Good semi-bituminous coals and smalls for cement and lime making are much inquired for and in lean smalls there is still nothing to dispose of. Briquets are rather dull and will certainly not be improved by a rise in the price of pitch, which is foreseen for this month.

There is no abatement in the excellent demand for domestic fuels; for anthracite it may even be termed very strong, especially from France. The scarcity of supplies is causing prices to go higher. Prices quoted for coke are nominal.

Prices for industrial coals have been reduced 2 fr. on semi-washed half-bituminous smalls, washed lean smalls, and coking smalls; 7 fr. on washed half-bituminous smalls; 3 fr. on half-bituminous and lean peas; 2 fr. 50c. on briquets.

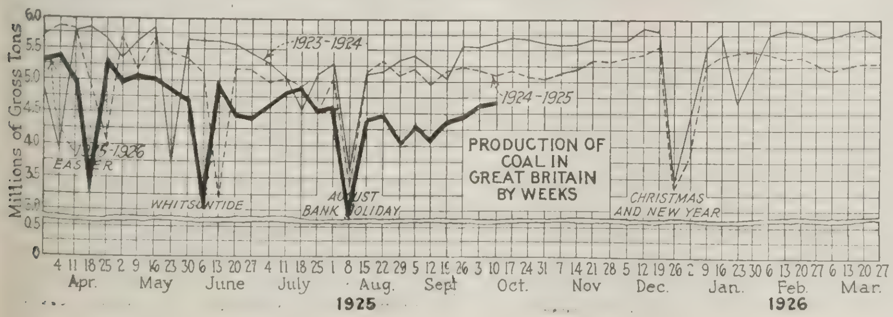
For domestic coals increases have been made of 5 fr. on half-bituminous through coal, 50-60 per cent; 10 fr. on half-bituminous and anthracite beans; 15 fr. on half-bituminous nuts, anthracite nuts and anthracite cobbles; 5 fr. on half-bituminous cobbles.

### Industrial Coals Reviving in French Market

In the French coal market a revival in the textile and glass-making trades is making itself felt in the consumption of industrial coals. In domestic grades the situation is even better than might have been hoped for a few months ago.

The Nord and Pas-de-Calais collieries having finally agreed to raise to 40 per cent the "living costs bounty," the prices of certain sorts of coals—sized coals particularly—will be increased, but, quotations on the whole will not be greatly modified.

Imports of free German coals, which can be brought into France only under special import permits, have not been important thus far, as the French Government has been desirous that such German fuels purchased on the free market be considered as "prestations in kind" and paid for by the Payment Agent of the Reparation Commission, as in the case for indemnity coals. The Germans were at first unwilling to accede to this demand, but the pressing necessity of selling their coals seems to have put them in a more conciliatory frame of mind.



### Normal Tone at Hampton Roads

Hampton Roads business is about the same as last week, except that coastwise movement is somewhat stronger. Approaching cold weather in some sections gives promise of a livelier market and has a slight tendency to strengthen prices. Foreign trade is falling off, but bunker business is about normal.

Movement to Canada, which had strengthened the market for months, has fallen to a minimum, due to shipments of Welsh coal. None of it has come this way, however. The tone of the market is fairly strong—approximately normal for this season.

### Export Clearances, Week Ended Oct. 24, 1925

# News Items From Field and Trade

## ALABAMA

The byproduct coke plant of the Republic Iron & Steel Co., located at Thomas, which has been in course of construction for the past year, was placed in commission last week. There are fifty-seven ovens and necessary facilities and equipment for the preparation and storing of all the various coal byproducts. The plant is modern to the minute in every way and was constructed by the Koppers Co., of Pittsburgh, Pa.

The Tennessee Coal, Iron & Land Co., Bessemer, is planning the development of a town for its employees, equipped with water works and electric lights.

L. E. Boyette, of Birmingham, is interested in the development of coal lands in Blount County, Ala.

The Brown Lumber Co., with main office at Fayette, is contemplating development of coal mines on its holdings near Tuscaloosa.

## ARKANSAS

Preliminary arrangements have been perfected by A. M. Malone and his associates and articles of incorporation will be applied for in a few days by the Ouita Coal and Railroad Co., which will build a railroad line into the old Ouita coal basin and carry on extensive mining operations in that section, which was the scene of the first mining activities in the Russellville field. Officers of the company, which will be capitalized at $150,000, are: A. M. Malone, president; D. R. Dorente, vice-president; W. D. Brogdon, secretary, and C. E. McKoin, treasurer.

## ILLINOIS

B. F. Bliss, of Chicago, was appointed receiver Oct. 7 for the Union Fuel Co., operating mines in Sangamon County. The appointment was made by Judge E. S. Smith, in circuit court, at Springfield.

The properties of the St. Louis Coke & Iron Co., east of Granite City, was bid in at public auction at noon Oct. 20 for $3,000,000. The successful bidder, C. H. Hand, of New York, represented the holders of the $6,800,000 first mortgage bonds, $3,099,000 of preferred stock and 92,000 shares of $5 par value common stock. It is anticipated that the sale will be approved immediately by the United States District Court at Springfield, so that an early reorganization of the company can be effected. The new company will be incorporated under the laws of either Delaware or Maryland and have about $2,000,000 of additional capital. This will finance the installation of a new blast furnace and other improvements to the plant.

## KANSAS

James Howat, a miner, brother of Alexander Howat, deposed president of District 14, United Mine Workers, and George Brown, a former miner, were found dead in a house in which they "batched" near Girard, Oct. 21. Several empty whiskey bottles and one containing some liquor indicated that they had drunk poison "hooch," and the coroner considered an inquest unnecessary. Howat was 50 years old. He was born in Scotland. Brown was 70 years old and had not worked for several years because of his age.

A Kansas coal digger, Ludwig Reindhaler, of Croweburg, committed suicide Oct. 16 by tying a stick of dynamite about his neck and lighting a fuse attached to it. Reindhaler was said to have been acting queerly three years.

## KENTUCKY

The government last week placed two sixty-car orders for mine-run coal through Louisville jobbers, the Drabelle Yager Coal Co. getting a contract for delivery on the Ohio River at Addison, and the Southern Coal Co., at Owensboro, also for river work. It is reported that the coal was sold on a delivered basis, which would figure about $1.25 f.o.b. mines. The business was placed under option whereby the buyer can take as much more coal at the same price.

Coal had an important bearing on car-loading by the Louisville & Nashville R.R., which broke all traffic records for August and September and also set its largest day on record, according to President W. L. Mapother. On Oct. 8 7,144 cars were loaded and moved. In August 168,181 cars moved; and September broke that record with 171,165. October is expected to run over 180,000. It is believed that the final quarter of the year will far exceed past records.

## MISSOURI

James C. Wilson, president of the Wilson Coal Co., Kansas City, Kan., was fined $100 in police court in Kansas City, Mo., Oct. 22, on a charge of misrepresenting coal he sold a buyer on the Missouri side of the line. The charge was supported by the Coal Credit & Correct Weights Bureau, of Kansas City, Mo., an association of retailers organized to promote public confidence in the industry by maintaining a high standard of ethics in the trade. Wlison was accused of delivering Hume (Mo.) coal on an order calling for Cherokee coal. His defense, supported by witnesses, was that "Cherokee" was a name used by the trade to denote a particular vein of coal, and that to be "Cherokee," coal need not come from the Cherokee County (Kansas) field. He charged his arrest was persecution by Missouri dealers to prevent his competition on their side of the line.

Operation has been resumed at the Trenton mine after a period of idleness lasting since last spring. It is expected that near capacity production will be attained within a few weeks.

## NEW YORK

The fires of 55 coke ovens of the Hudson Valley Coke & Products Co., Troy, were lighted at 7 a.m., Oct. 18 and after 24 hours of operation more than 1,000 tons of coke had been produced. Full production is expected by Nov. 1, at the latest, when the byproducts plant, producing coal tar, benzol and various other chemcials, is expected to go into operation. The gas produced incidental to the manufacture of the coke is to be sold at wholesale to the utility companies supplying Troy, Albany and Schenectady.

"Earnings of the United States Distributing Corporation and subsidiaries are good and those of one of its principal subsidiaries, Pattison & Bowns, have not been reduced so far by the anthracite suspension," was the statement on Oct. 23 of Harry N. Taylor, president. "Earnings of Pattison & Bowns have held well as a result of storing a large amount of hard coal before Sept. 1, from which deliveries have been made since."

## OHIO

Bids will be opened Nov. 16 by J. E. Harper, director of Public Welfare, Oak and Ninth streets, Columbus, for two steel coal bins of 500 tons capacity each and an ash bin of 50 tons capacity for the Hospital for Epileptics at Gallipolis; also for an electric coal elevator with a capacity of 50 tons per hour and a larry to haul the same capacity.

Dumpings at the docks of the Hocking Valley Ry. for the week ending Oct 21 totaled 210,582 tons. The same docks have handled 6,933,921 tons up to and including Oct. 21 as compared with 5,556,473 tons during the same period in 1924. Dumpings at the docks of the New York Central lines for the week ending Oct. 21 were 43,715 tons; or for the entire season up to that date, 2,143,534 tons. Dumpings for the season of 1924 up to Oct. 21 totaled 102,817 tons.

J. P. Brennan, state purchasing agent, who expected to receive bids the latter part of August for approximately 225,000 tons of either nut, pea and slack or run of mine coal for 25 state institutions, has not yet set the date. Mr. Brennan has been buying coal on the open market, rather than on contract, to make sure that strikes will cause no delay in the shipment. At the same time he is getting fuel from 10c. to 30c. per ton cheaper than would be possible on contract. "I will continue to buy on the open market, unless conditions change materially, and prices are reduced," he said. To date about 75,000 tons have been purchased.

The Y. & O. Coal Co. has resumed operations at its No. 1 mine at Amsterdam. The mine was idle for 18 months. Married men were given the first chance at the available jobs.

## PENNSYLVANIA

At a recent patriotic meeting held in Scranton under the auspices of the American Constitutional League an attempt was made by leaders of the United Mine Workers to introduce a resolution condemning the courts of West Virginia for injunctions and demanding that the government act in the situation there. The leaders of the meeting spragged the resolution, however, on the ground that it was of a political nature. The resolution was to the effect that the courts of West Virginia have denied the right of free speech to union mine workers.

A contracting company has started work on a pile foundation for a coal tipple at the Ella Mine at Milesville, on the Monongahela River, for the Hillman Coal & Coke Co. Construction is about to start also on a river tipple for Evan I. Brown, at Riverview, 35 miles above the mouth of the Monongahela River.

The Youngstown Sheet & Tube Co. will enlarge its coal mining property at Nemacolin. This mine, developed during the last five years, is now producing an average of 4,500 tons a day with output running as high as 5,000 tons some days. It will be expanded and new equipment purchased for a production of 6,000 tons a day.

Appointment of a fuel administrator to take over and have charge of the distribution of fuel at Erie, owing to the strike of anthracite miners, is being sought by the city's finance director, who plans to sound Governor Pinchot on the subject. While Erie is supplied largely from the bituminous district, the director felt that there would be suffering in the city during the winter.

The new breaker of Madeira, Hill & Co., at Marion Heights, is almost finished and the management hopes to have operations started in it once the strike in the anthracite field has ended. This breaker will take the place of two other structures once it begins to operate. The structure is built of concrete and steel throughout, and is equipped with the most modern machinery.

**A Coke Producing Plant in the Hills of New Mexico**

These coke ovens, boilers and power house are located in Dawson, N. M., and are owned and operated by the Phelps Dodge Corporation.

The Buck Ridge mine at Johnson City, said to be one of the most modern in the anthracite valley, is involved in an interesting legal battle. More than a year ago the operation went into the hands of a receiver. About this time it was placed in charge of Madeira, Hill & Co. of Philadelphia, which improved the mine in different ways, replacing old pumps with new electric ones and driving new tunnels to tap rich coal veins. Now it is rumored that other mining interests are using their influence with a Philadelphia banking concern which controls the Buck Ridge operations to gain possession. It is reported that the Madeira-Hill company has been notified of a change in the lease and that injunction proceedings are now contemplated.

Coal companies in West Mahanoy Township have launched proceedings in court in Schuylkill County with the hope of wiping out some of the high paying tax collector and school treasurer jobs in boroughs and townships. The coal companies, by far the heaviest taxpayers in the township, contend in court that it is out of reason for the school treasurer to receive a salary of $12,000 a year. The operators believe a salary of $5,000 would be ample and have asked the court to hand down an order to this effect.

The new steel washery at Coleraine, which will replace the abandoned colliery of Van Wickle & Co., is fast assuming definite shape. The new owners are said to be planning heavy production when the mine suspension ends.

The Margaret Coal Mining Co., located in Indiana County, has let a contract to the Fairmont Mining Machinery Co. to erect a rope and button conveyor at its mine.

Maintenance men assert that the coal companies in the Panther Creek region are making heavy reduction in the forces. Operations at the Lansford shops also have been curtailed due to the mine strike. Usually more than 600 are employed at these shops, but just now the working force does not exceed 200.

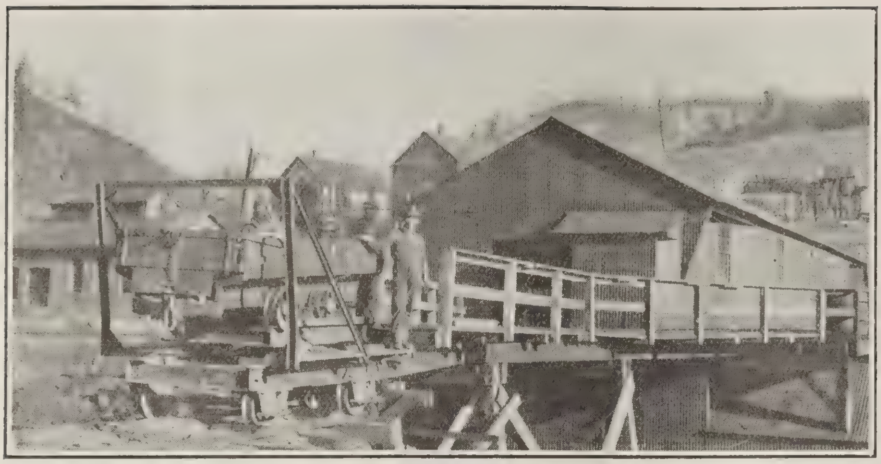
A new situation affecting the coal industry in the Pittsburgh district has arisen in the proposed abandonment of the slackwatering project in the Youghiogheny River which would make the stream more readily navigable. The United States Army engineers have suggested that plans for three locks in this river be abandoned and the immediate result has been many objections. There is a coal reserve of 14,000 acres in the lower Youghiogheny valley containing approximately 100,000,000 tons of coal, according to the Pittsburgh Coal Co., one of the principal objectors. The coal company points out that eventually consumers, principally steel companies, all along the Monongahela and Ohio rivers as far as Wheeling, will turn to the Youghiogheny valley for their coal supply.

## UTAH

H. H. Calvin, special representative of the United States Fuel Co. for the past two or three years, prior to which he was general salesmanager, has resigned to go to California. He is a son of the vice-president of the Union Pacific System and has been connected with the local fuel company since 1913.

## WASHINGTON

The engineering department of the Pacific Coast Coal Co. has announced that the two tunnels at the company's New Black Diamond mine, 20 miles southwest of Seattle, have been connected, and that the mine is expected to commence commercial production early in 1926. When in full working order the mine will produce about 2,000 tons of coal per day. About $1,000,000 has been spent in this development work since July, 1924. The town around the old mine will be abandoned and accommodations for the men will be provided in the locality of the new operation, which will give employment to about 500 men.



**End-Dumping Larry at Pond-Creek Pocahontas Co.'s Big 4 Mine**

This West Virginia operation disposes of slate by running cars carrying three and one-half to four tons of rock through the tipple onto an electric car-dumping larry. As this larry does not swing, it can dump over the end only. The track, as shown, is only about 50 ft. long so trolley wires are not in use, the larry being operated by a cable reel.

## VIRGINIA

The Virginia Iron, Coal & Coke Co. reports for the quarter ended Sept. 30, 1925, net income of $61,997 after interest, depreciation and taxes, equivalent after preferred dividend requirements to 30c. a share. This compares with net loss of $70,264 in the preceding quarter and net loss of $27,973 in the third quarter of 1924. Net income for the first nine months of 1925 totaled $209,038, equal to $1.15 a share, comparing with net loss of $73,380 in the corresponding period of 1924.

## WEST VIRGINIA

The sale of the Coal River & Eastern R.R. to the Chesapeake & Ohio Railway Co. was completed at a meeting of officials of both roads held in Washington on Oct. 15. Negotiations for the sale of the road have been going forward for some time. The Interstate Commerce Commission passed the final order for the sale of the road two weeks ago. This road is owned by the Coal River Collieries Co. It extends ten miles into Boone County between Seth and Prenter.

Fire of unknown origin late on Oct. 16 destroyed the blacksmith shop of the Starford Gas Coal Co. at Brydon, six miles west of Grafton. During a rainstorm the building burst into flames and burned to the ground in a few minutes. Officials said that burning of the shop resembled work of the conspiracy gang that operated in the Brydon section during the first five months of the year.

The Clarksburg District Mining Institute held a meeting Oct. 24, when plans were made for the revival of a mining extension class.

The coal industry was represented by a number of operators and sales agents who carried the message of Southern coal to New England when the visit of certain New England organizations last year was returned between Oct. 11 and 20 by representatives of Virginia, West Virginia and the Carolinas. In the party of West Virginia operators were T. E. Farrell, vice-president of the Pocahontas Fuel Co.; E. E. White, president of the E. E. White Coal Co.; Major W. P. Tams, Jr., president of the Gulf Smokeless Coal Co.; W. E. E. Koepler, secretary of the Pocahontas Operators Association, and others. R. H. Gross, president of the New River company, who lives in Boston, and numerous others connected with the smokeless industry joined the party on its arrival in New England.

The Wise Pocahontas Coal Co., Fairmont, has increased its capital from $50,000 to $100,000.

Increased production from the mines of eight coal companies operating in Raleigh and Wyoming counties in the Winding Gulf field, is to be made possible, according to an announcement, through a reorganization effected by Pittsburgh and New York capital. The Cory-Mann-George Corporation, of New York, is to be the sales agent for the various companies concerned. Included in the reorganization are the following companies: Sullivan Pocahontas Coal Co., Wood-Sullivan Coal Co., Pickshin Coal Co., Mead-Pocahontas Coal Co., Tommy Creek Coal Co., Raleigh Fire Creek Coal Co., Harty Coal Co., and the Barkers Creek Coal Co. Howard N. Eavenson is to become vice-president and treasurer of the New organization.

The Raleigh-Wyoming Coal Co., Glen Rogers and Edwight, is distributing a Safety-First button 1¼ in. in diameter in red, white and blue, "the colors of our national flag, believing that a careful man is at the same time a good citizen."

The Lovejoy Coal Co., composed of Masontown and Uniontown (Pa.) interests, has purchased the mine of the A. L. Black Coal Co. at Maidsville, near Morgantown, which consists of 30 acres of Sewickley coal land.

A sudden call for 3-in. lump coal came to the Northern West Virginia coal fields last week. Some of this coal is moving to the piers, but other shipments are being made to Jersey City and as far north as New Hampshire by rail, according to reports. The shortage of anthracite has created a demand for this size.

The American Coal Co. of Allegany County, McComas, is installing five type Y American pneumatic coal separators at its Crane Creek plant to treat coal passing $\frac{1}{8}$-in. screens as one size with a portion of the dust removed through aspiration. As a result of this additional installation all $\frac{1}{16}$-in. screens, or one-third of the total in the plant, will be removed. Two older type separators also will be removed, which with the screens will partly equip an additional plant. After this change has been made the coal company will treat all coal passing 2-in. screens with two less sizes than heretofore. The plant will have a capacity of 300 tons per hour when the work has been completed. The American Coal Cleaning Corp., Welch, is supplying the separators and the coal company is erecting them.

J. W. McCarthy has been arrested in New York City and is held under $5,000 bond to apear in federal court at Charleston on Nov. 17, it has been announced by W. C. Volkerdin, post office inspector. McCarthy, who operated the Kanawha-Hazard Coal Co., with general offices in the Moore Building at Charleston, is charged with using the mails to defraud. It is alleged that McCarthy represented to coal operators that he had an unlimited market for coal of all kinds and would place orders with various companies for coal to be delivered to consumers. After he secured orders he would have the coal shipped to the consumers, collect for the shipment and then fail to pay the operator for his product, according to the authorities.

## WYOMING

About 100 members of the United Mine Workers in Rock Springs have enrolled in the Rock Springs Labor College, which started class work Oct. 20. Six courses, including economics, civil government, journalism and public speaking, are offered. Co-operation between ministers of various Protestant churches and the labor leaders make this college possible.

Despite a recent heavy increase in production, the Rock Springs district coal output for September was approximately 20,000 tons short of the same period in 1924.

Following its policy of making home owning possible for its men, the Union Pacific Coal Co. is offering more lots for sale in the Brooks and Clark additions to Rock Springs. Recently the company agreed to deed to the City of Rock Springs a three-acre tract in the center of the city for the creation of a city park. The people who have been living in this district will be given preference in the purchase of the proffered lots. Sections of the former course of Bitter Creek also have been deeded to Rock Springs and when the filling in process is completed, will form salable lots and streets. The creek has been changed from a course through the center of the city to the northern edge, traversing coal and railroad company ground.

### CANADA

The house of William Hopkins, in the village of Newcastle in the Drumheller coal district of Alberta, was wrecked by an explosion on the night of Oct. 15. A stick of dynamite with a fuse attached had evidently been used. Hopkins is a coal miner and had worked at the A. B. C. mine during the strike and was quite active in the United Mine Workers organization. Some material was stolen from the Newcastle powder house two days before and this is apparently the use to which it was put. An investigation is being made by the authorities and the miners belonging to the U. M. W. A. have appealed to the federal Minister of Labor and the Attorney General of Alberta asking for protection from further outrages.

## Traffic

### Rates to Cement Mills Put on Parity

The Interstate Commerce Commission has ordered railroads hauling bituminous coal from the Pittsburgh-Youghiogheny, West Virginia, Meyersdale and Cumberland-Piedmont districts to Union Bridge, Md., via the Western Maryland direct and via the Baltimore & Ohio and Western Maryland railroads through Cherry Run, W. Va., to apply rates to that destination no higher than the charges contemporaneously maintained by the same carriers to Security, Md.

Tidewater Portland Cement Co. et al vs. Cumberland & Pennsylvania R.R. Co. et al (mimeographed report). The principal complainant, a cement mill, pointed out that the existing adjustment forced it to pay 51c. per ton more on coal from the Cumberland-Piedmont and Meyersdale regions than did its competitors at Security, 39 miles less distant. At the same time the Commission declined to disturb general group interrelationships or to find the rates to Union Bridge per se unreasonable.

### Demurrage at Mines Outlawed

The attempt of the Tennessee R.R. to charge demurrage on empty cars placed at the mines for coal loading and on cars held under load awaiting billing instructions has come to grief. The Interstate Commerce Commission, in a mimeographed opinion in I. & S. Docket 2443, *Demurrage on Coal and Coke*, has ordered the carrier to cancel tariffs under suspension, which excepted such cars from the exemption provided in the Uniform Demurrage Code. The carrier sought to justify the exception to the general exemption on the ground that per diem charges on foreign equipment held at the mines were a serious drain upon its financial resources and further alleged that operators, recognizing this, had agreed several years ago to reimburse it for such car rental when cars were held over 48 hr. following the first 7 a.m. after placement. Refusal of the Roach Creek Coal Co. to continue such payments led to the filing of the tariff under suspension.

"Although respondent (carrier) states that the proposed schedule was published for the sole purpose of recovering its car hire cost on cars under load," concludes the Commission, "It would be applicable to all cars. In other words, it would have the effect of largely offsetting respondent's cost of car hire by assessing shippers an amount equal thereto beyond a certain time. Respondent is under obligation to furnish the equipment necessary for the transportation of traffic tendered to it, and if it does not possess such equipment the charges paid for the rental thereof cannot be considered as an item of expense which is not included in the rate. * * * The exception here proposed has no apparent purpose except to transfer respondent's car-hire costs to the coal operators."

### Tombstone Rates Approved

Rates on bituminous coal and coke from mines in Colorado and New Mexico, groups 1, 2, 3 and 4, and from Albuquerque, San Antonio and Gallup, N. M., to Tombstone, Ariz., are not unreasonable, holds the Interstate Commerce Commission in a recent mimeographed opinion dismissing the complaint in *Harry E. Macia v. A. T. & S. F. Ry. Co. et al.* Complainant had sought the application of main-line points maintained at Fairbanks to Tombstone, located on a branch-line of the Southern Pacific 9 miles distant from Fairbanks. The differential against Tombstone is 70c. per ton.

## Obituary

**Warren S. Lee**, 72, veteran merchant, banker and president of the Russett Coal Co., operating mines in the Buckhorn district of Cambria County, and who also had a hand in the development of the Wopsonnock district some years ago, died at his home in Altoona Oct. 18.

**Senator William Roche**, of Halifax, N. S., died on Oct. 19, at the age of 83 years after an illness of several months. He was extensively engaged in the steamship and coal business and was one of the prominent business men of Halifax, where he was born and spent most of his life. He represented Halifax in the Canadian House of Commons for some years and in 1910 was appointed a member of the Senate.

## Industrial Notes

**The Robert June Engineering Management Organization**, of Detroit, Mich., has acquired control of the **Electric Flow Meter Co.**, at Kansas City, Mo., formerly the Hyperbo-Electric Flow Meter Co., of Chicago, and will henceforth operate the business under its own management with executive offices at 8835 Linwood Ave., Detroit. Robert June becomes president of the company, J. M. Naiman, formerly general manager, becomes vice-president, consulting and chief engineer, with Major W. W. Burden, of the Robert June Organization, as treasurer.

A direct factory branch has been opened in Birmingham by Fairbanks-Morse & Co., with offices in the Birmingham Athletic Club Building, Fourth Avenue and Twenty-third Street, North. A large warehouse will be established for the distribution of Diesel engines, electric pumps, motors, domestic light and water plants, gasoline engines and feed mill machinery. M. B. Brister, formerly located in New Orleans, will be the local manager.

**The Climax Engineering Co.**, Clinton, Iowa, announces the appointment of the Coast Machinery Corporation, 829 Folsom St., San Francisco, Calif., as sales representative for California. Other new agencies are as follows: The George W. Whitehead Co., 61 The Terrace, Buffalo, N. Y.; Edward C. Dingman, 1005 Keefer Building, Montreal, Can.; Harvard Turnbull & Co., Ltd., 912 Excelsior Life Building, Toronto, Ont.; the Advance Contractor Repair Co., 1332 W. Lake Street, Chicago, Ill.; the Mine & Smelter Supply Co., 121 West Second St., Salt Lake City, Utah; McDonald & Burgman, Jacksonville, Fla.

**The Electric Controller & Mfg. Co.** announce the appointment of **Eicher & Bratt**, Seattle, as representatives for the sale of E. C. & M. control equipment in Oregon, Washington, Alaska, and the Panhandle district of Idaho. Eicher & Bratt also represent in their territory the Pittsburgh Transformer Co., Jewell Electric Instrument Co., and the Electric Power Equipment Corporation.

At a reorganization meeting of the board of directors of the **Cincinnati Electrical Tool Co.**, Cincinnati, Ohio, the following officers were elected: Joseph Wolf, president and treasurer; R. K. LeBlond, vice-president; Edw. G. Schultz, secretary. This company manufactures a large variety of portable electric drills, grinders and buffers, has branch offices in all the large cities and also is represented in the principal foreign countries. Plans are under way to move into larger quarters soon and expand the business in a general way.

**The Diamond Power Specialty Corporation**, of Detroit, announces that the territory of the **Lathrop-Trotter Co.**, 733 Union Trust Bldg., Cincinnati, Ohio, which has been sales representative for the Diamond Power Specialty Corp. in the Cincinnati territory for many years, has been extended to take in Indianapolis and adjacent territory in central and southern Indiana.

Consolidation of the Weir Frog Co. and the Kilby Frog & Switch Co., to be known as the **Weir Kilby Corporation**, is announced. O. DeG. Vanderbilt, Jr., is president of the company; E. M. Kilby, first vice-president, and J. K. Lansdowne, vice-president. Sales offices and plants are at Cincinnati, Ohio, and Birmingham, Ala.

**The General Electric Co.** has moved its Birmingham (Ala.) office from the Brown-Marx Building to the fourth floor of the new twelve-story office building of the Alabama Power Co., Sixth Avenue and Eighteenth Street, North.

## Association Activities

D. H. Morton was elected president of the **Kanawha Coal Operators Association** by its directors after the directors had been re-elected at the annual meeting of the association held at Charleston W. Va., Oct. 15. Mr. Morton was advanced from the vice-presidency he held last year, succeeding John Laing, of Charleston, as president. E. O. Dana was elected vice-president and John L. Dickinson and D. C. Kennedy were re-elected treasurer and secretary respectively. President Morton, W. M. Wiley and F. O. Harris were chosen as members of the executive board. The board of directors consists of Mr. Laing, Mr. Dana, Mr. Wiley, Mr. Harris, C. A. Cabell, Holmes Morton, W. C. Mitchell, J. L. Warner and E. M. Merrell.

**Coal Operators Association** will hold a combined annual members' meeting, golf tournament, banquet and efficiency meeting in Knoxville, Tenn., Nov. 20. The board of directors, with C. W. Henderson, president, will meet at the association headquarters in the Bankers Trust Building, followed by the general members' meeting and annual election of officers at 10:30 a. m. At 2 p. m. the Southern Appalachian Efficiency Association, composed of the mine superintendents and foremen, will meet. In the afternoon a golf tournament, arranged by Victor N. Hacker, will be held at the Cherokee Country Club, where the banquet will be held at 7 p.m. with Judge H. B. Lindsay as toastmaster. Transportation and other officials of the railroads serving this field will be guests at the banquet.

## Coming Meetings

**Canadian Institute of Mining and Metallurgy.** Annual western meeting, Nov. 3-5, Winnipeg, Manitoba, Can. Secretary, George C. Mackenzie, Drummond Bldg., Montreal, Que., Can.

**Illinois Mining Institute.** Fall meeting, Nov. 6 and 7 at West Frankfort, Ill. Secretary, Frank F. Tirre, St. Louis, Mo.

**Harlan County Coal Operators' Association.** Annual meeting, Nov. 18, at Harlan, Ky. Secretary, E. R. Clayton, Harlan, Ky.

**American Society of Mechanical Engineers.** Annual meeting at New York City, Nov. 30-Dec. 3. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**Fourth National Exposition of Power and Mechanical Engineering.** Nov. 30 to Dec. 5, at Grand Central Palace, New York City.

**Coal Mining Institute of America.** Annual meeting, Dec. 9-11, Pittsburgh, Pa. Secretary, H. D. Mason, Jr., P. O. Box 604, Ebensburg, Pa.

**American Mining Congress.** Twenty-eighth annual convention, Dec. 9-11, Washington, D. C. Secretary, J. F. Callbreath, Munsey Bldg., Washington, D. C.

## New Companies

**The Rogers Coal Co.,** Drakesboro, Ky., capital $25,000, has been incorporated by C. A. Rogers, I. C. Rogers and Edgar Rogers.

**The Janney Coal Mining Co., Inc.,** New York City, has been chartered at Albany, N. Y., with $25,000 capital, all subscribed, to operate coal mines. G. M. Janney, Robert R. Schote, 1 Broadway, and G. T. Goldthwaite, 20 East 35th St., New York City, are directors and subscribers.

**The Tar Distilling Corporation,** New York City, has been chartered at Albany, N. Y., with capital of 1,000 shares of no par value, to produce coal, coke and coal tar, by James H. Tully, N. P. Callaghan and Wallace Ingraham, of 25 Broad St., New York City.

**The Muir Pratt Coal Co.** has been chartered by W. C. Muir and Andrew Dunlap, 310 42d St., Birmingham, Ala.

**The Carnall Coal Co.,** capital $15,000, has been incorporated by Wm. McKinnin and Walter Cobb, of Fort Smith, Ark.

**The New Garland Pocahontas Coal Co., Bluefield, W. Va.,** has been chartered by S. N. Huffard and Kenneth C. Patty.

**The Logan-Winifred Coal Co.,** Logan, W. Va., with a capital of $25,000, has been incorporated by G. R. Claypool and G. W. Raike.

**The White Star Coal Co.** of Cincinnati, Ohio, was incorporated under the Ohio State laws on Oct. 16 and will be directed by Louis H. Stone as general manager. Stone until Sept. 1 was general manager of the Southern Coal & Coke Co. Mines at White Star, Mathel, Hamby and Adelia, Ky., are in the group for which this company will be the distributing outlet.

**The Oxita Coal & Railway Co.** has been formed at Russellville, Ark., with A. M. Maline as president to develop coal land in the Russellville region.

**The Republic Coal Co.,** of Mulberry, Kan., has been granted a Kansas charter. The capitalization is $30,000. The incorporators are J. A. Holland, Silas James and A. E. Ginther, all of Mulberry. The company last August purchased the electric shovel and holdings of W. P. Kelley, of Pittsburg, and since then has been producing 200 tons a day on the 200-acre lease, which is near Mulberry.

## Trade Literature

Heisler Locomotive Works, Erie, Pa., has issued a new bulletin on **Haulage**, divided into sections according to the different industries served. Increases in haulage capacity from 60 to 100 per cent are described. The bulletin contains 18 pp.; 8½ x 11 in.; illustrated.

The D. O. James Mfg. Co., Chicago, Ill., announces its new general catalog No. 99, of 288 pp., covering its complete line of products, including **gears, speed reducers and couplings**. It is well illustrated and contains general engineering data of interest to engineers, designers and purchasers of transmission equipment.

**Portable Air Compressors.** Sullivan Machinery Co., Chicago, Ill. Bulletin 77-N. Pp. 31; 6 x 9 in.; illustrated. Describes three distinct types: WK-312 and WK-314, gasoline-engine-driven; WK-34, belt driven from a tractor, and WK-32, driven by belt from an electric motor.

**IXL Speed Reducers.** Foote Bros. Gear & Machine Co., Chicago, Ill. Catalog No. 26. Pp. 80; 8½ x 11 in.; illustrated. This revised edition contains much new engineering information pertaining to the solution of problems involving spur- and worm-gear reducers. Tables, formulas, practical problems and general information of interest to engineers and plant executives are included.

The Diamond Power Specialty Corp., Detroit, Mich., has reprinted a bulletin entitled **"The Best Paying Investment in the Power Plant,"** featuring Diamond Valve-in-Head Blowers and containing information of interest to power operators.

The Kuhlman Electric Co., Bay City, Mich., recently issued a handbook entitled **"30 Years of Uninterrupted Service to the Electrical Industry."** It contains practical engineering data and material for the electrical or consulting engineer and the man who operates transformers.

**Diamond Core Drills.** Sullivan Machinery Co., Chicago, Ill. Catalog No. 80. Pp. 80; 6 x 9 in.; illustrated. Describes the process of diamond core drilling for prospecting mines and mineral lands and for engineers' test borings, and includes specimen lists of diamond drill equipment, instructions for selecting an outfit and a chapter on setting up and operating the machine under ordinary field conditions.

# New Equipment

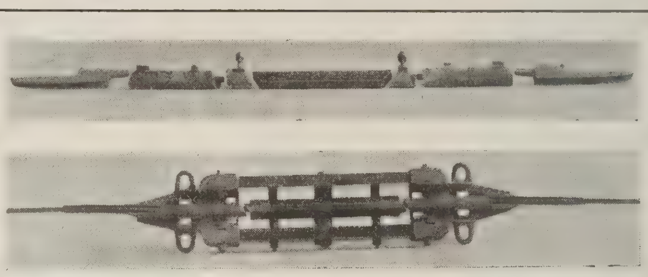
## Double Insulation Improves Section Insulator

Long life, double insulation, bronze arcing tips and renewable underrun are the outstanding features of the new section insulator manufactured by the Westinghouse Electric & Manufacturing Co.

Section insulators should be capable of breaking a motor-load current up to 750 amp. and 650 volts under all conditions without holding the arc, and should also insulate trolley lines from each other and from the ground, up to 750 volts without noticeable current leaks, under all weather conditions. This newly designed section insulator meets these requirements through the use of double insulation, a hickory runner and two air gaps. It has 8 in. of minimum runner insulation. It is claimed that this hickory runner is admirable for its special use, and in addition, is able to withstand severe weather conditions due to the treatment that it undergoes in construction. The additional insulation in the form of air gaps is particularly effective because it has bronze arcing tips of high tin content on both sides—an entirely new feature in air gap insulation. The skewed air gaps will break a current under all weather conditions. They have ample blow-out surface.

Long life of the insulator is assured by its sturdy construction. The main body of the insulator is made of such material that it will last indefinitely. End castings are made of high grade malleable iron, thoroughly cleaned, treated and zinc flooded. All bolts and studs are made of phosphor bronze, while end clamps and arcing tips are of bronze with a high tin content.

Smooth underrun is another feature of this new design. The complete underrun can be replaced without removing the insulator from the line. In fact all wearing parts can be replaced by merely removing two hexagon nuts, and without disturbing suspension spans, trolley wires or insulator bodies. Bayonet approaches help prevent hammer blows as the trolley wheel enters the insulator.



**Increases Its Utility**

## Pleasing the Public

CONSIDERATION for the public has been the watchword of the anthracite producer, wholesaler and retailer, since the quarrel between the operators and miners started.

From the very first the operators desired to forestall trouble. They asked for arbitration. They desired to continue working at the old scale till the matter was arbitrated. They sought a contract so long, yet so subject to reasonable modification, as would assure the public of a continuous supply of coal.

Denied these three they went into conference with the miners and listened patiently day by day to their arguments for more wages and allowances. All in vain; the miners broke up the conference and called a strike.

Then when anthracite began to get scarce, the retailers agreed to buy bituminous coal in place of anthracite, and the hard-coal producers volunteered their services, established to encourage the sale of anthracite, to sell the rival fuel. The retailers also put coal on one side to take care of the small consumer.

Nothing more could have been done. Mr. Lewis realizes that the readiness of the hard coalers to help the consumer has won the hearts of the public, and he is making much capital out of an alleged identity of anthracite and bituminous operators. The fact that the president of one anthracite company, which he manages and does not own, has a son who is in a position of authority in some West Virginia soft coal properties means nothing even if true. The statement that the Glen Alden Coal Co., an anthracite corporation, has a bituminous subsidiary is incorrect. It is true, however, that the Lehigh Valley Coal Co. has a 1,000-ton mine in the bituminous regions. Some of the leading independents like Madeira-Hill, Whitney & Kemmerer, the M. A. Hanna Co. and the Dodsons have bituminous mines, but only one of these companies produces low-volatile coal. Moreover these are smaller concerns, and what are they among so many?

The anthracite companies are in no way profiting from the strike. It is to them a most unfortunate event. They do not like to see soft coal replacing hard but they wish the public to keep warm, they seek the goodwill of the people and do not want a surrender made to those who are creating trouble for operators and public alike.

## Is the Miner a Man Or a Ward?

WHY IS THE PUBLIC so interested in whether the miner is well paid? The ditch digger's family has to live just like the miner's. Why not be as much anxious to see him get a square deal? The difference is that the miner has by good advertising and the threat that he will cut off the public's coal supply made the man on the street take an interest in something that really is not any more a matter of concern to him than whether his iceman, the girl behind the counter at the store or the telegraph boy is getting a sustenance wage. These people shift for themselves and it seems that the public might leave the miner equally free to do the same.

If he is not paid a wage as good as the wage of other men, he can look for other jobs. There are plenty of them. Why worry the public? The cure is in his own hands. Calvin Coolidge hasn't said so but he seems to take the point of view that the miner is just one among many and not entitled to the paternalistic interest of the Government. Is the miner a man or is he a ward? When the federal authorities interest themselves in wages the activity should be general not specific and should be devoted to those industries where the pay is lowest.

## As an Engineer Thinks

NEED for the engineer to take part in the direction of national affairs is being expressed wherever any of the profession meet. This sentiment has been advanced by Herbert Hoover and more recently by Governor Dern, of Utah, at a meeting of the American Institute of Mining and Metallurgical Engineers. In point of fact has not this estimation of the engineer as the real thinker of thinkers been somewhat overdone?

The engineer truly thinks concretely and, as he is, or should be, college bred, he has a degree of idealism which seems to come to most of those who set themselves off from the world for three or more years to study and reflect. But as the rest of mankind does not think quite so concretely, does not analyze, arrange and argue on the basis of statistics and has a lesser degree of idealism it is easy for the engineer to get into a wrong psychologic attitude and to fail accordingly in his leadership. He may draw his conclusions from masses of figures; he may exercise his judgment with due idealism but when he comes to make his suggestions he must speak in the terms of his hearer's psychology. To think in one formula and argue on the basis of another requires a finesse that few engineers acquire.

The engineer is loath to cast overboard all the elaborate figures he has done so much to accumulate. He is prone to endeavor to preach a turgid idealism that the public is slow to accept unless an emotional appeal is added to the argument. He gives pro and con for every statement forgetting that to the public the sum of many pluses and minuses is always zero regardless of which has the greater value. The man who leads is he who lets the public infer that success has only one sign.

As an engineer thinks so is he? Only rarely do we find men who like study and reflection delighting also in the hurly-burly of political life. We seldom discover men who find pleasure in long columns of figures and tabulations who are also gifted in the art of moving the passions of mankind. There are such men, patient in detail and yet capable of forensic effort, but on the whole one class of men is prone to think and the other to talk and the talkers will never be thinkers nor the thinkers talkers, more's the pity.

## What Will Britain Do in May?

AT THE DINNER of the Academy of Political Science in New York last week Lord Thompson, a British brigadier-general and former Secretary of State for Air, received all the honors that Americans usually give to foreigners who come preaching a gospel of beneficence. He prefaced his remarks with a statement that if profits and a living wage are mutually exclusive so that if there is a living wage there can be no profits and if there are profits there can be no living wage, then the profits may have to be foreborne.

But it must be remembered that the mine workers of Great Britain are working only seven hours a day and really have little right, therefore, to be discussing the living wage. Furthermore, they have repeatedly and deliberately restricted output as has been shown by actual tests and by the output of miners in mines run on the co-operative basis.

At one mine having a 4-ft. 6-in. seam of coal with a good roof it was decided by the local union that four gross tons a day was all a man could be expected to get with the aid of a compressed-air "radial drill." The company demurred at setting the daily stint so low. "Accordingly the mining manager," we are told, "described as a man of 50, rather large, in company with an underground manager of 60, who also was very large showed the officials [of the union] what they could do. These two men averaged 15 tons 7 cwt. [17.19 net tons] each for a seven-hour day. After this demonstration the union officials put the figure no higher than eight tons for a day's work."

The big talk about inefficiency in British mining is largely for the consumption of the public. The miners are opposed to efficiency. They think it will lay off British workmen. Nowhere is this idea less justified. In Great Britain, the export trade is important. The British mines are being thrust out of that trade by high prices and if efficient methods of production were adopted it would be foreigners who would be laid idle and not Englishmen, Welshmen or Scotchmen.

Then again, if coal were cheaper, more coal would be bought within the confines of the island. The cost of steel, for instance, would be greatly reduced if coal were cheaper. Yet again, the house fires of Great Britain are used with amazing frugality. It is true they waste coal and heat, but the British householder goes without a fire in as many places as he can. The high price is making him more frugal than ever. In America so well are the houses heated that it would be difficult to increase the sale of domestic coal, at least in normal years. This year there will be some real frugality, it is true, but usually there is no great opportunity to expand domestic demand. But in Great Britain that should not be so.

Another significant fact is that the tonnage per man has been decreasing for years in the British Isles, from 332 tons annually in 1883 to 220 tons annually in 1924 despite the introduction of machinery. There is evidence that the British workman wants a living wage but is none too anxious to earn it. It might be well also to suggest that the lowest living wage is not the basis for calculation. Some of the mining areas which pay low minimum wages really should not be working at all.

What will Great Britain do in May when the subsidy ends? Will she give way to coercion and renew the subsidy? Let us think awhile. The wages cannot be so much lower in mining than in other industries, or the miners would desert the mines. That is what happens in other industries in Great Britain when wages get too low. Why should the miner and railroad man be protected more carefully than any other workman? Why indeed? Solely because they are organized and paralyze the public of Great Britain when they strike. Here, as in England, it is not the wrongs of the worker but the threat of idle factories and cold houses that makes the public act. His Lordship did indeed work a wonderful spell on the Political Scientists of the United States at their annual powwow, that they doffed their thinking caps in his honor.

## Keep Right With the Community

NO COMPANY is justified in ignoring the interests and goodwill of the community in which its plant is located. Friction perhaps cannot always be avoided. The new company officials are interlopers in an old order long established; the superintendent is a newcomer among the first families of the village. Even the county school superintendent, the sheriff, and the distinguished representatives of the bar may be eclipsed temporarily by the new coal company representative.

So it is well to go easily, creating goodwill as one goes. There are assessments to be levied, taxes to be paid, safety laws to be enforced, roads to be maintained, and it is well to have the community favorable to the company success. The miners, too, react to an atmosphere of favor or of criticism. They get some of their ideas from local opinion, and when a newspaper reporter comes into the town he is led or misled as the case may be according to the prevailing sentiment.

No operator seems to care about the local editor who sends press notices to the city and to whom the city reporter directs himself when he comes to town for a story. Knights of the pen working for yellow papers are usually bent on getting just the kind of material they have been sent for rather than the truth, but their work is eased and the result made more certain if the village is well sprinkled with those who wish the company ill.

If the industry would thrive it must have friends at home. It must cultivate the goodwill not only of the miners but of the community. Those industries have been most successful that have looked beyond their employees to the employees' families and beyond the families to people of the immediate vicinity—the merchants, the farmers and others forming the community bordering on the mine. No company will succeed that believes itself to be operating in a vacuum.

MANY ENCOURAGING TRENDS toward greater prosperity are to be observed in the business currents of the country. The Atlantic States Shippers Advisory Board has just completed a survey showing, for instance, that distribution of goods at wholesale and retail in the Eastern Atlantic states for the last quarter of this year will show an increase of from 10 to 15 per cent over the last quarter of 1924. This fact means something to the basic industries of the country.

# Reconditioning Cuts Valier Mine Costs

## Labor and Power Saved and Safety Increased By Program of Changes that Already Has Made Total Reductions Estimated at 20c. a Ton

**By Frank H. Kneeland**
Associate Editor of *Coal Age*
New York City

VOLUME OF OUTPUT from a coal mine usually exerts a potent influence upon the expense of producing coal but it is not always the controlling factor. A determined effort on the part of the operator to cut down his mine costs may be even more potent. This has proven true at the Valier mine of the Valier Coal Co. in southern Illinois. Although this mine for a brief period last year held the world's record for tonnage brought through a single opening during a single shift, thus establishing its claim to greatness, its output for the year dropped 21 per cent which would, in the natural course of events, increase the cost per ton. But the total production cost during 1924 actually was reduced 20c. a ton. And this reduction is still going on. The company hopes for even lower costs through better equipment and management.

### IT *CAN* BE DONE

IF AN operator determined to reduce his mine costs 50c. a ton just where would he begin?

This article tells where the Valier Coal Co. began—and shows it got somewhere. Since the early part of 1924 a program of cost reduction has been in progress at Valier. During that year changes in equipment and method were made involving the expenditure of $48,100. They are resulting in annual economies estimated at $76,380. Even though the mine worked only 158 days in 1924 as compared with 231 days in 1923 and produced less than a million tons instead of equaling the 1923 output of 1,226,447 tons, the operating expense was reduced 10c. a ton and total production cost was lowered 20c. a ton. More improvements have been added this year.

During the past few months a whole series of improvements in various details of operation have been made at this mine, all of which have as their primary object either a reduction in the labor force or a decrease in the expenditure of power. Such changes and alterations cannot fail to make their influence felt on the cost sheets and increase the financial efficiency of the operation, which, in the last analysis is the kind of efficiency in which the stockholder feels the keenest and most lasting interest. On the other hand, some of the improvements made at this mine have aimed at safety and safety alone. It is well recognized, however, that greater safety pays.

The changes made and contemplated at this mine naturally divide themselves into four main divisions, namely: Economic changes below ground, economic changes on the surface, safety measures below ground and similar measures on the surface.

Although the original plan of the bottom permitted the handling of a large volume of coal, it possessed certain clearly defined drawbacks. In the accompanying drawing the original layout is shown in light lines and the improvements made during the past summer are shown heavier. The main haulage headings extend east and west. By the original arrangement when trips came from either side the haulage locomotive uncoupled from them and had to wait until the bottom motor pushed the cars into the bottom before it could couple to the waiting empties and move them back into the mine.

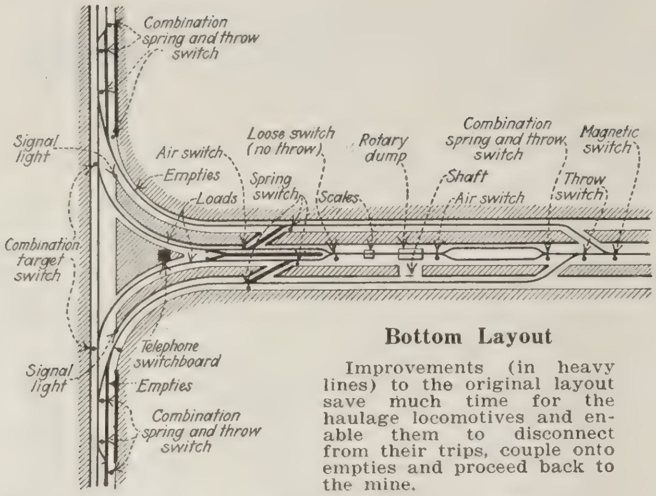
By slightly separating the loaded tracks and laying a motor track between them, switching at the shaft bottom has been minimized. Suppose a trip comes from the west side of the mine. The haulage motor proceeds onto the left-hand loaded track leading to the dump as far as the slant passage or "shoofly" leading to the left-hand or west-side empty track. Here it uncouples from the trip, travels through the shoofly, couples onto the empties there waiting and returns immediately back into the mine.

The forward end of the loaded trip is left in such a position that it may be engaged readily by the shifting ram that works back and forth across the top of the bottom locomotive. By means of this ram or push bar, which is moved by means of a rack on its lower side engaging with a pinion on a shaft actuated by a handwheel from the driver's seat, a trip of cars upon either track may be pushed forward to the dump. Trips coming from the east side are treated in exactly the same manner. Thus there is no waiting of one motor for another on the main bottom.

A trip from either side must, however, be fed practically through the dump before another loaded trip from the same side may proceed into the bottom. This condition is indicated by a signal light at the entrance to the bottom, the position of which is shown on the drawing. A green light indicates that the sidetrack is clear and that a loaded trip from that side may proceed. A red light signals that loaded cars still block the shoofly to the empty track and the loaded trip accordingly waits on the main haulage road until the light changes.

### MANY TYPES OF SWITCHES USED

This bottom is decidedly interesting also because of the various types of switches employed in its layout. Thus, there are spring switches, air switches, throw switches and magnetic or solenoid switches as well as combinations of spring and throw types. Several of the switch stands both here and elsewhere throughout the mine are provided with targets similar to those used on railroads. These are lighted electrically thus obviating all danger of igniting either gas or dust from



**Bottom Layout**

Improvements (in heavy lines) to the original layout save much time for the haulage locomotives and enable them to disconnect from their trips, couple onto empties and proceed back to the mine.

an open flange. Annual savings in 1924 alone are estimated at $9,182.

During the past summer the dump at the shaft bottom, which is of the rotary or revolving type discharging two cars at a time was raised $1\frac{1}{2}$ ft. and the door or valve that controls the flow of coal to the bins below it so arranged that it can be thrown by compressed air. This saved the services of one man and rendered operation of the door quick and positive. At this mine the skips are unusually large, holding three mine car loads of coal or about 13.2 tons each. When this mine broke the world's record on Nov. 25, 1924, by hoisting 8,664 tons of coal in a single shift the hoisting cycle averaged 44 to 45 sec. so that quick, positive manipulation of this valve is essential.

### Rolls Make Heavy Grades

Although the No. 6 coal bed of Illinois is a highly persistent measure and fairly uniform in thickness, it is so subject to rolls and minor faults in this locality that it is the exception rather than the rule that any plan of projection can be strictly adhered to. When, however, a definite plan is followed, as must be the case with the haulage roads if a large output is to be obtained, the grades are liable to be heavy both with and against the loads.

This was the case at Valier and in order to minimize the evil effects of such grades both on the rolling stock and the power consumption much of the main haulage roads have been regraded, bottom being lifted in some localities and top brushed in others. In one place a cut 13 ft. deep has been made. While such work is expensive it means savings in power, decreased wear and tear on both track and rolling stock and increased safety and reliability in operation.

All the main haulage tracks in this mine have been overhauled and all bonds put in proper shape. In this work copper terminal bonds have been electrically welded to the rail flanges. These bonds are located on the inside of the rail and span the fish plates, or splice bars thus assuring a good return for the power circuit.

Automatic reclosing circuit breakers have been installed below ground tying all sections of the mine together electrically. This will obviate delays arising from the overloading of any one section as well as doing away with the services of two men. An investment of $7,500 results in a saving of $3,372 a year.

### Change Motor-Generator Station

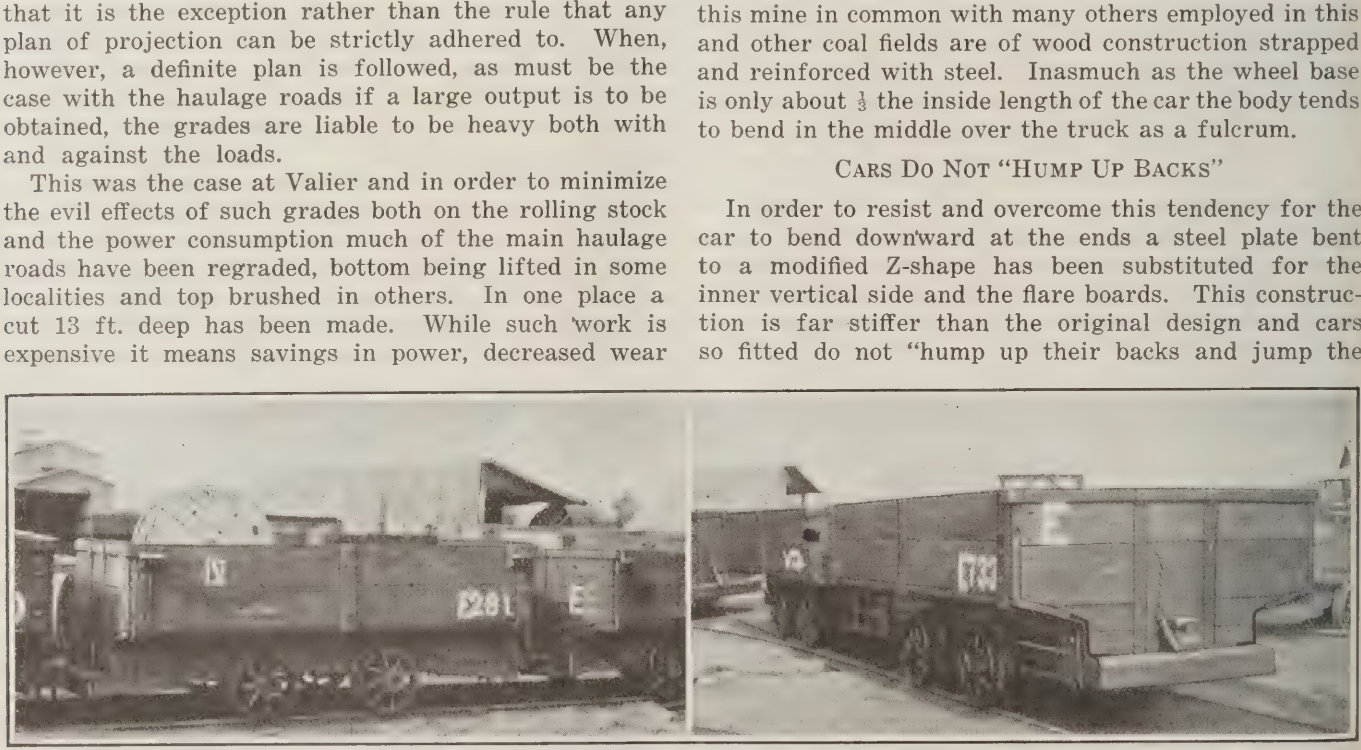
The underground motor-generator station has been relocated. Thus it has been brought more nearly to the center of the underground load which it serves, resulting in better voltage regulation. The capacity of feeder lines has also been increased so as to obtain adequate power for haulage and other purposes throughout the entire mine.

A change has also been made in the lubricant employed for the mine cars and in the means of applying it. Grease was first substituted for oil as a mine car lubricant and then an electrically operated grease gun replaced the hand methods employed in grease application. The saving made by installing the electric gun was $2,000 last year and the total reduction in lubrication cost was $12,000 more.

Nor has improvement to the car been confined to means and methods of lubrication, even though these accomplish much in the way of lessened expense, increased reliability and decreased wear and tear. The design of the mine car has been improved so as to increase its longitudinal stiffness and its resistance to drooping at the bumpers. The cars originally used at this mine in common with many others employed in this and other coal fields are of wood construction strapped and reinforced with steel. Inasmuch as the wheel base is only about $\frac{1}{3}$ the inside length of the car the body tends to bend in the middle over the truck as a fulcrum.

### Cars Do Not "Hump Up Backs"

In order to resist and overcome this tendency for the car to bend downward at the ends a steel plate bent to a modified Z-shape has been substituted for the inner vertical side and the flare boards. This construction is far stiffer than the original design and cars so fitted do not "hump up their backs and jump the



**Drooping Tendency of Old Mine Cars Overcome in New Design**

On the left is an old car of all-wood construction. The tendency toward drooping at the bumpers and humping in the center over the truck is plainly discernible. On the right appears a car of the new design in which is embodied a plate bent to the form of a modified Z affording great longitudinal stiffness. Each car is numbered and those for the east half of the mine are stenciled E and those for the west half W. Thus the cars are kept separate, even though passed through a common dump.

**Where 6,000 Bits Are Sharpened Daily**

Two men, two oil furnaces and two bit sharpening machines do work that probably would require from 12 to 16 men if equipped only with ordinary forge and anvil. Bit sharpening is practically a manufacturing process and manufacturing methods may be followed in its performance.

track" as the old ones sometimes had a way of doing. The difference in the appearance of the old and new cars is readily apparent from the accompanying illustrations.

In order to improve the "nervous system" of the mine and render inter-communication between its various members quick and sure a complete telephone system has been installed. This is fitted with a central exchange the location of which is shown in the drawing. It is similar to that employed in large office buildings and small towns. Where noise is liable to interfere with the use of outlying phones these are installed within a suitable booth provided with a door. The coal mine thus borrows a leaf from the metropolitan telephone system's notebook.

For a long time, probably ever since this mine had been started, men had been employed to carry sharp bits to the machine runners. This was obviously extravagant in man power yet followed precedent established long ago when "nipper boys" carried the pick points of the old pneumatic punchers. Bits for the undercutters are now handled through a regular bit station. Sharp bits are shipped to this point in bulk. Each machine runner has a bit bucket or container and sharp bits to a number equal to that of the dull ones turned in at the close of the previous cutting shift are issued to him at the beginning of the night's run. This one change, which was instituted at practically no cost, is responsible for aggregate savings estimated at well over $5,000 per year.

### Savings Made Above Ground

But changes and savings effected at this mine have by no means been confined to the underground. The original railway track grades were such that handling of cars in the mine yard and at the tipple was difficult and expensive. It was often necessary to resort to pinching in order to move the cars before, during and after loading. These tracks have now been regraded so as to obviate all pinching and car retarders have been installed under the tipple.

Control of all cars while loading has been centralized in the hands of one man stationed in a booth suspended between the lump and egg tracks. This man can easily oversee all loading operations and move the cars as necessity may require. It is estimated that savings in labor costs alone aggregating at least $4,000 per year will result from this method of car control.

Refuse from the picking tables as well as slate and rock were formerly dumped into a bin together. From here this mixed material was shoveled into wagons or carts and hauled away to be used in making fills. Today the pickings and the mine rock are segregated, the rock being discharged into flat cars from which it is unloaded by means of a locomotive crane fitted with a clamshell bucket. Instead of wasting the pickings from the tables this material is now utilized as fuel.

For years materials and supplies intended for use at the mine—ties, props, sand, cement, machinery and what not—were unloaded from cars on the track above the tipple and hauled to storage by teams or trucks. Last summer a "material track" was installed rendering it possible to unload timber direct to the timber yard and other supplies to the appropriate warehouse or storage shed beside the track. The savings in time and man power thus rendered possible are obvious.

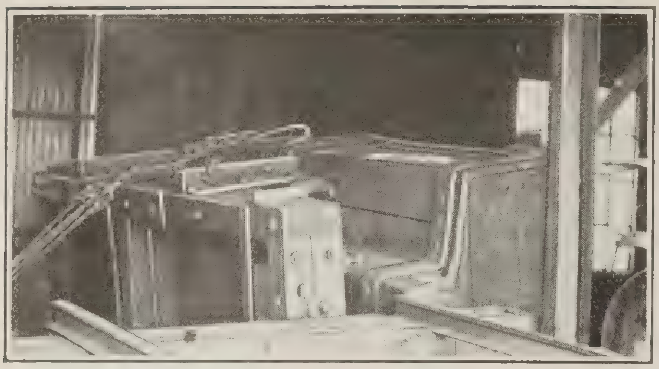
### Motor Truck Does Hauling

For performing the general hauling and trucking about this mine a motor truck has been substituted for horses and wagons. One truck of this kind, largely because of its greater speed of travel, has been able to supplant two teams. The services of one driver and, upon occasion, those of at least one helper have simultaneously been dispensed with.

Steam is generated to heat water for the bath house. Fuel for this purpose was formerly delivered to the steam plant in mine cars from which it was shoveled by hand to the floor space in front of the furnace doors. A rotary, or what might more correctly be termed a tip-over dump has now been installed to discharge these cars of fuel. The track on the platform of this dump turns sidewise on trunnions or a shaft below it so that

**Car Control Underneath the Tipple**

All of these tracks have been so regraded as to avoid all necessity for using pinch bars. Control of the movement of all cars under the tipple is centered in the hands of one man stationed in the narrow booth in the upper foreground at the top of the ladder.



**One Way of Reducing Fuel Cost**

This simple device that overturns by gravity but is righted by an electric motor saves shoveling fuel coal from the mine car to the boiler room floor in front of the furnace. It thus greatly simplifies and cheapens the problem of fuel supply.

the car is nearly overturned and completely discharged by gravity. It is righted by means of a small electric motor arranged to wind a cable onto a spool. This cable passes through a set of tackle blocks one of which is attached to the side of the car. This same motor is employed to pull the loaded cars up the grade leading into the fuel shed of the heating plant. The cost of this installation was $1,800 but the saving is expected to be $1,372 a year.

### HAS 37 MILES OF ENTRY DUSTED

Until about a year ago inert dust for treating the various roads and headings in this mine was purchased. A pulverizing plant has now been erected, however, at which roof rock is ground for rock dusting purposes. Approximately 37 miles of entry have already been dusted in this mine and several miles more yet remain to be similarly treated. All of these passages will be redusted every six months or as much oftener as may be necessary. The plant last year reduced dust costs $7,184 or nearly enough to pay the whole first cost of $7,500.

As originally constructed, the man and material shaft at this mine contained a car cage traveling in one compartment and a counterweight in another. Coal is hoisted at this shaft for docking and boiler fuel purposes only. Cars were pushed off the cage, dumped and recaged by hand. A pneumatic de- and re-cager has been installed in this tipple that does the work formerly performed by two to three men. This device works promptly and consumes a comparatively small quantity of air.

This machine is simple in construction and is easily operated. It consists of a cylinder made of steel pipe provided with a piston, piston rod, crosshead or ram sliding in guides, and the necessary valves, admission and exhaust pipes and the like. The front of the crosshead or ram is provided with both a buffer and a chain fitted with a hook. When a car comes up on the cage the ram is pushed forward and the chain hooked to it. Air admitted to the cylinder forces the piston back, retracting the ram and pulling the car off the cage and onto the dump. After the car has been discharged and righted the ram is thrust forward pushing the car onto the cage. The general appearance of the ram is plainly seen in one of the accompanying illustrations. The whole device is controlled by a 3-way cock, conveniently located.

### SAVES $2,744 A YEAR ON BITS

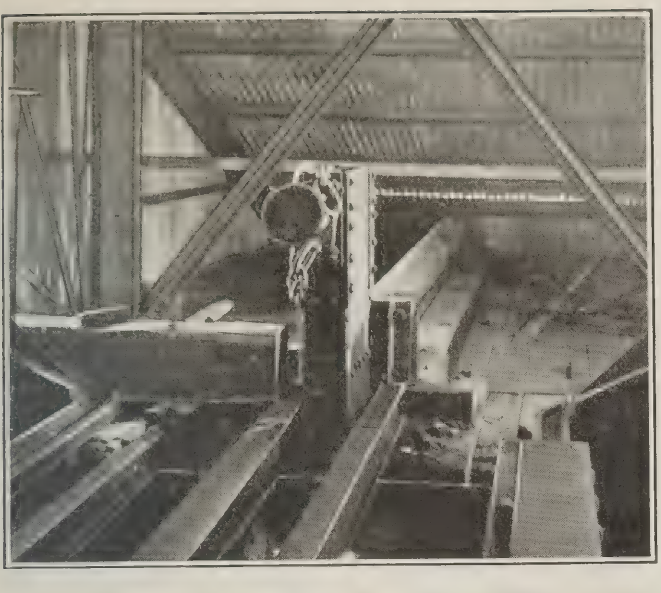
In coal of the consistency here mined it requires nearly one sharp cutter bit for each ton of daily production. Oil fired bit heating furnaces and bit sharpening machines have been installed in the shops at this mine which enable two men to sharpen about 6,000 bits per day. Each bit can be sharpened or resharpened from 15 to 20 times before it is worn out and must be discarded. But sharpening now costs annually $2,744 less, thanks to an investment of $1,100.

Several of the changes and improvements recently made at this mine have been intended primarily to attain safety. Their economic value is thus indirect and intangible although by no means negligible. First and foremost of these comes the practice of rock dusting. As has been stated a dust grinding plant has been built at this mine and many miles of underground passageways have already been treated to a coating of inert dust. This process will be continued until all headings have been similarly treated. These passages will be redusted twice each year or as much oftener as is necessary to maintain the inert content of the mine dust at the inexplosive point.

In addition to rock dusting the mine uses water sprays to reduce coal dust danger. These have been installed over the rotary dump at the foot of the main shaft and in the two runarounds which the empties

**Saved $7,000 Last Year**

This shows the dust grinding plant which last year reduced dust costs, $7,184, while under process of construction. It has long since been completed and placed in operation. Nearly 40 miles of heading in this mine have been treated with inert dust and several more miles remain to be similarly treated. Periodic analyses of the mine dust are made from time to time.



**Pneumatic Ram Does Three Men's Work**

This de- and re-caging device performs the work formerly done by two to three men and does it promptly. Its consumption of air is low and its upkeep practically negligible. It was built in the local shops.

traverse before they return to the active workings to be reloaded. The sprays lay the dust that may be present either in the coal or clinging to the cars themselves.

A partition wall has been built in the air shaft. This is of concrete and separates the intake air compartment from the cage and counterweight compartments. Originally this shaft contained a car cage and a counterbalance. The counterbalance has been replaced by a double-decked man cage onto the lower deck of which a weighted car may be run when coal is to be hoisted. When men are to be raised or lowered this car may be run off the cage and men accommodated on both decks. Double-decked landings have been provided at both the top and bottom of this shaft, and explosion doors also have been placed at the top.

Underground, the oil switches controlling the current to this mine have been inclosed in a fireproof structure. By this means fire originating from any cause within this switch station cannot be communicated to the outside and similarly fire from the outside cannot enter.

### BOTTOM CAN BE ISOLATED

Steel doors sliding on overhead tracks and moving back into narrow slits or kerfs cut into the ribs have been installed upon either side of the air shaft foot. By this means this bottom can be completely isolated in case of emergency.

The mine air and dust are analyzed regularly. Analyses of mine air are made once each week with a portable Burrel apparatus with an Orsat apparatus as a check. Samples of the dust along the headings, haulage roads and like passages are also taken and analyzed at regular intervals. In addition to a safety engineer two other safety men are employed who devote their entire time and effort to the cause of safety. It should be mentioned also that closed lights only (electric cap lamps) are used in this mine.

Some further changes are contemplated but have not yet been made. These, like those already enumerated, have as their objects either increased safety of operation or savings in the expense of coal production. Among them might be mentioned:

(a) The installation of car stops at the foot of the air shaft to facilitate the movement of cars at this point and render running of cars into the sump an impossibility.

(b) Rounding off the shoulder at the foot of the air shaft. As this shaft is at present constructed the heading at its foot leads off at an abrupt right angle. The air coming down the shaft is thus compelled to make an abrupt turn of 90 deg. at this point. This wastes power, and since the ventilation must be maintained continuously even small savings in power expenditure represent appreciable economies at the end of a year's time.

(c) Deepening the sump at the foot of the main hoist shaft and installation of an elevator and cross conveyor so that this sump may be cleaned mechanically. Naturally there is more or less spillage into any shaft sump. This, probably, is in greater volume where skip hoisting is practiced than where the cars are brought to the surface for discharge. At this mine with present arrangements the sump must be cleaned by hand. This expense, which is now appreciable, could be materially lessened by the installation of a mechanical cleaning device, the operation of which would entail only the cost of power and the wear and tear on the machinery.

Most machines require tuning up and adjustment after installation; most large mines must undergo a process that is exactly analagous. The changes made and to be made at Valier and here briefly enumerated partake of this nature. They have already reduced operating and total production costs. Their completion will unquestionably reduce these costs further—possibly even attaining the 50c.-a-ton reduction which is the goal.

**Air Shaft Has Double-Deck Landing**

This shaft contains two hoisting compartments. In one of these travels an ordinary car cage; in the other moves a counterweight cage, upon which a counterweight car can be run or removed at will. This cage is double decked and double landings are provided at both top and bottom of the shaft. Thus the counterweight cage even though far narrower will accommodate approximately as many men as the car cage.

# Don’t Be a John Hardy—*Prevent* Explosions

**By S. L. Morrow**
Birmingham, Ala.

THE MOST ESSENTIAL and the most important thing for a miner to do in the event of a mine explosion is to help prevent that explosion. Accidents of all kinds, including explosions, are constantly wandering around looking for a place to happen; and in ninety-nine cases out of a hundred they cannot happen without the help of some human being. Let every miner take this home to himself and think of it daily.

### WHY THIS WAS WRITTEN

DOWN in Alabama they are pushing safety. The Joseph A. Holmes Safety Association with 27 chapters in that state is backed by the Alabama Mining Institute, the U. S. Bureau of Mines, the state mines department, insurance companies and mining men of all degree. Monthly chapter meetings in some of the mining towns draw 800 or 900 people. This fall a series of papers has been prepared to be read as a part of the program at each chapter meeting. This story is one. It is printed here in the hope that it may be helpful to Holmes chapters everywhere.

Is there a coal mining man who wants to form a partnership with a mine explosion and by his help cause it to occur? Your answer, of course, is no; in big letters. All right then, it is up to each of you to be constantly on the lookout for any dangerous condition in and around your mine and when you find one either correct the condition yourself or report it promptly to the mine foreman or safety inspector.

Keep an eye on all new men who come into the mine and see that they do not jeopardize their own lives or yours. Prevent the explosion and the remainder of this paper will be worthless.

Stupidity and carelessness are first and second lieutenants in the army of accidents. They walk constantly by the side of every miner. Today they go to the face of the Fifteenth Left with John Hardy. John has had many years’ experience in the mines. He reaches his working place and through force of habit taps the roof in various places with his pick. One place sounds hollow and he starts back to the last cross-cut for a timber. Lieutenant Carelessness whispers in his ear: ‘Aw, what’s the use? That place won’t fall for a week.” John hesitates and turns back and greets his new buddy who has just come in.

An hour later the “drummy” place in the roof lets go, crushing a mine car, and the new buddy narrowly misses getting caught. The wreck cleaned up, the two finish loading out their coal and move into the aircourse to shoot down the coal for the next shift.

There is a little pool of water at the face next to the right-hand rib and rather than get his feet wet John points his auger too far to the right, boring his hole well back in the solid. After the hole is up, John looks at it and scratches his head a moment and starts to bore another hole, when Lieutenant Carelessness whispers: “Aw, let ’er go, she’s not much on the solid.”

John sends his buddy across to the heading to gather up the tools while he loads the holes. He places powder in all his holes properly fused. He hesitates at the right rib hole. Caution tells him to bore another, but Carelessness wins and he places his powder in the improperly drilled hole in preparation for shooting it.

John now goes to his clay box and finds it nearly empty. He picks up the box and starts back to the side track for more clay when Carelessness says: “Gee, that’s a long walk, why take it?” Lieutenant Stupidity now chips in with: “Go on and use coal dust. You used it twice last week and nothing happened. Besides you are using permissible powder and it is safe.”

John hesitates and is lost; he turns back to the face and tamps up his holes using what clay he has, finishing out with coal dust. The two lieutenants stand by and watch him complete the job and then, Lieutenant Stupidity says to Lieutenant Carelessness: We’ve done a good job. Let’s beat it to a safe place.”

John gathers up his tamping stick, tools and surplus fuse and puts them into his tool box. As he starts back to the face he notices quite a quantity of dust on the bottom and makes a mental note to tell the mine foreman to send the sprinkling crew in the next day.

John lights his shots and then walks rapidly back to the second cross-cut and sits down to wait till they go off. In a few seconds come the dull boom of three or four properly placed shots, a short interval and then a sharp crack like a cannon, a bright flare of flame and a gust of wind.

A few seconds later smoke and flame are seen belching out the mouth of the slope accompanied by a sharp, roaring, cracking sound. It is as though Hell itself has broken loose.

### Death Strikes Fierce Blow

A death-like lull follows for a moment. Then sharp cries of agony break the stillness. They come from two men blown off the tipple who lie on the ground broken and bleeding.

Men with horror stricken faces rush from the shops, the other plant buildings and the superintendent’s office. Soon the level heads bring order out of chaos. Doctors and ambulances are summoned. Rescue apparatus is brought out and rescue parties are organized.

In the camp mothers and daughters stop short at the sound of the explosion and with blanched faces exclaim: “My God, Number 2 Slope has gone up.”

At the schoolhouse, children crowd to the windows and gaze toward the mine in wide-eyed terror, each with a prayer in his heart—“God save my daddy.”

Now come back with me into the mine.

John Hardy’s place was in the Fifteenth Left off the main haulage. Three thousand feet outby the Fifteenth Left and about 600 ft. from the bottom of the slope the first right and left cross-entries turned at right angles to the main haulage, each on a separate air split. The right cross was only driven a few hundred feet.

The left cross was in about 4,800 ft. driven as a main entry with the First North turned to the right at 2,200 ft. and the Second North at 4,400 ft.

When the explosion occurred, Assistant Mine Foreman Billings was just coming out of the First North into the left cross. The force of the explosion blew out his carbide lamp and nearly blew him off his feet. He quickly recovered himself and relighted his lamp. In a few minutes panic stricken men began to pour out of the First North and a brattice crew and a track crew came rushing down the cross-entry from the direction of the Second North. All were making for the main haulage and the slope. It was with great difficulty that Billings got them to halt long enough to explain that it was certain death to try to get out and that their only hope was to go back up the First North and barricade themselves in. All were convinced, except two men who persisted in going out. Their bodies were found by the rescue party some 12 hr. later several hundred feet from the slope.

"Well, boys," said Billings, "We must get busy." He turned to the boss trackman: "Jack, will you take Henry and go back to the Second North and get all the men together and barricade yourselves in, while I go with the rest up the First North?" Both Jack and Henry agreed and started on their way.

### LEAVES MESSAGE FOR RESCUERS

Before starting Billings picked up a cap board and with the flame from his carbide lamp wrote: "Men in First and Second North, follow arrows." He laid the board in the middle of the track. "All right, boys,, I have just counted noses and find that there are 22 of us. Come on. Every man bring his dinner bucket and his water and pick up any thing you see that will help build a barricade. It's a good thing we are on short turn today or there would have been more of us in here."

Every 200 or 300 ft. Billings marked an arrow on the roof with his lamp.

The First North was in about 1,200 ft. with three room entries turned to the left. These all had ventilating doors. As they passed these entries Billings ordered each of the doors propped open to short circuit the air.

Arriving at the Third Left, Billings decided to build his barricade across the First North, just inby the Third Left. The barricade would have to be 12 ft. wide by 5 ft. high. It would be necessary to build a second wall across the last cross-cut in the First North.

Billings at once began issuing orders. He sent two men to the face of the Third Left to get a car and all the shovels they could find. He sent five men under the boss bratticeman to the last cross-cut in the First North with instructions to start building a barricade, consisting of two rock walls about 2 ft. apart with a well-tamped filling of dirt, cautioning them to make it air-tight.

### CONSTRUCTING THE BARRICADE

Billings opened a water valve in the sprinkling line and found that there was water, but at low pressure, meaning that the pipe was broken somewhere up the slope.

The two men from the Third Right returned soon with a car and several shovels and Billings sent four men with the car back to the Second Left sidetrack for a car of tamping clay which he had seen as he passed.

Thirteen men were left including himself. Eleven of these Billings put to collecting rock from the gob wall and piling it near where they would build the barricade. He then took one man with him to the face of the First North. He stopped at the last cross-cut and gave the crew some instructions. This cross-cut had an air-course track in it and the crew had brought out a car and a number of shovels from the face of the air-course.

Billings, with his one man, went on to the face and found a car loaded with bugdust; they found two shovels and a bucket of drinking water in the heading tool box. They loaded these on the car of dust and proceeded to push it back in the entry to the site of the main barricade. In the meantime the crew had collected a pile of rock for the walls.

The four men who had been sent for clay arrived soon and Billings ordered it unloaded just inby the barricade. He had the car of bugdust unloaded and then sent six men with the two cars up the entry with instructions to load them with dirt from the bottom.

**Fire Stop**

Had lumber been handy this type of fire-stop might have been erected by "Billings" and his men trapped by the explosion. As a matter of fact this particular one was built in the King mine at Princeton, Ind., and helped seal off a bad fire last summer. It contains an 18-in. wall of clay with ends hitched into the ribs and the top luted with clay to seal it tight.

He selected a place for the barricade where the entry had been driven "tight" in order to turn the Third Left. With the remainder of the crew he started two rock walls across the entry with about 2 ft. of space between them. When these walls were about a foot high, the space between them was filled with dirt and coal dust well tamped. This was repeated for each foot of wall until within a foot and a half of the roof. The outby wall was then built up to the roof, and the connection with the roof carefully plastered with mortar made of clay and water from the sprinkling line. All the dirt possible was then thrown up against the outby wall. The inby wall was then finished to within a few inches of the roof, and all the dirt possible packed in. A few minutes work and the inby wall was completed to the roof and well plastered with clay all along the roof and for a foot down.

Billings then examined the wall all over and decided to chink up the ends of each rib with clay. This done, he ordered all hands to the face to help the crew on the other wall. Some clay was left and this was loaded in a car and taken along. They found the wall nearly done. They were short of clay so they plastered the connections between the outer wall and the roof, and when the inner wall was completed, they rolled a sufficient number of jumpers and stuffed these tightly between the top of the wall and the roof.

### Completed in Less Than Two Hours

Billings carefully examined the wall and pronounced it as good as it could be made. He looked at his watch and remarked that it had been just an hour and three quarters since the explosion had occurred.

"Now," said Billings, "Let's all go back to the other barricade." On arriving, he asked: "How many dinner buckets in the crowd?" Checking revealed 14, with 2½ or 3 gal. of water but little food left over from lunch.

"Use this bucket I found in the heading to drink out of, and when it is empty fill it from your dinner buckets. Go easy on drinking so as to make the water last as long as possible," continued Billings.

"I want to compliment all you boys on the way you have kept your heads and worked for the last two hours.

"Now everybody scatter out about 40 or 50 ft. and sit down. Now put all your lights out. My light will be enough to see by and we will save both carbide and oxygen."

When these orders were carried out Billings started to walk up and down from one end of the crowd to the other, talking to them in order to keep up their morale as much as anything else.

"Boys," he said, "I have seen some of you at our Joseph A. Holmes Safety meetings and some of you I haven't. Some of you who do attend don't seem to pay any more attention than the law requires. I've got you all here now where you can't get away and I am going to tell you a few things which I think you ought to know.

"In the first place, this entry is about 350 ft. long from the barricade to the face. It is about 12 ft. wide and 5 ft. high. It, therefore, contains 21,000 cu.ft. of air. Add to this about 2,000 ft. in the six cross-cuts out to the stoppings, and we have about 23,000 cu.ft. or somewhere near 850 cu.ft. of air to live on until rescued.

"One cubic yard of normal air will sustain a man for an hour if he is at rest and breathing quietly. Lights consume oxygen and that is the reason I ordered lights out.

"Normal air contains 21 per cent oxygen, I learned by studying the subject carefully. A safety lamp or open torch will go out when the oxygen is reduced to 17 per cent. A carbide lamp just burns in air containing 13 per cent of oxygen and goes out when the percentage is less.

"Every breath we take we consume a certain quantity of oxygen and give off about an equal quantity of carbon-dioxide.

"We have about 850 cu.yd. of air in here and there are 22 of us, therefore, at a cubic yard per hour per man, we have enough air to last us—let's see, now—about 39 hr.

"A man moving about consumes twice as much air as one perfectly quiet. I am moving slowly so as to keep the air mixed. I had you scatter out to keep the carbon-dioxide which we exhale from our lungs from collecting in one place.

### Learned Program at Safety Meetings

"I am going to tell you the most important things to do if you find yourself entrapped in a mine by an explosion or mine fire. I got this all down by heart because I took an interest in safety at the association meetings:

"Keep your head. Weigh your chances of getting out through some opening away from the direction of the explosion.

"If you are sure you are cut off from any escapeway, quickly head for the deep workings with the idea of building a barricade before the poisonous gases reach you.

"Leave marks behind to assist the rescue party in locating you.

"Take everything possible with you that will help build a barricade, such as tools, boards, brattice cloth, etc. Don't forget your dinner bucket, water and carbide.

"Barricades such as we have built today are easier to make air-tight than if built of boards or brattice cloth.

"As you go back, short circuit the air in every possible way to prevent the gases from following too rapidly.

"If there is compressed air in the mine try to locate your barricade so that you will have an air valve in your space behind it. If there is no valve, break the pipe. The compressed air will add to the available supply back of the barricade.

"Always include as much space back of the barricade as possible regardless of the number of men in the party.

### Always Conserve Air

"After the barricade is built, sit down and remain quiet, to conserve all air possible. Lights out.

"Do not barricade yourself in a place known to give off methane, as the gas may be ignited and cause the death of the entire party.

"If you'll think back over the things we have just done, you'll see we've followed out these directions pretty closely."

Billings sat down midway the crowd and continued:

"I have been reading one of the Bureau of Mines circulars about the number of men who have been saved by building barricades after explosions and fires.

**How's the Gas?**

When men are on rescue work, such as was done by the team hunting for "Billings" and his trapped crew, they make haste slowly, testing carefully as they go. Here, they are looking for the telltale blue cap that indicates the presence of inflammable gas. The second man from the right in his right hand carries a small wooden cage in which is a canary. These birds are particularly susceptible to the influence of poisonous carbon monoxide. When the little bird falls from its perch it is time for men to watch their step carefully, for they are in the same deadly atmosphere.

The record shows that in 16 disasters 431 men built 25 barricades and 324 lives were saved out of the 431. Men have been rescued from behind barricades after having been imprisoned as long as seven days. In the Dolomite No. 3 explosion in our own district 50 men were rescued from behind a barricade after about 5 hr. So you see that it pays to keep your head and barricade yourself in.

"I feel confident that we are safe and that it is a question of only a few hours until we will be reached."

Slowly the hours dragged along. Some of the men tried to sleep. Others tried to carry on a subdued conversation. A few broke down and cried, murmuring brokenly: "I wish to God I could send word to my wife and babies."

Finally, at 4:30 a.m. 13 hr. after the explosion, there came a sound of knocking on the outside of the barricade, and a muffled voice saying: "Hello, anybody back of the wall?" As one man the crew sprang up, shouting: "Yes, yes." All lamps were quickly lighted and two or three men grabbed picks and started to attack the barricade. "Hold on," shouted Billings, "Let's find out if the air is all right outside." He shouted through the wall: "Is it safe to come out?" "Yes," came the reply, "The air is all right."

Some of the men attacked the wall with picks, others clawing feverishly with their bare hands helped break a hole through. In a few minutes they were all through the wall and greeting five helmet men with helmets off, their test canary as chipper as a lark in its cage.

Questions and answers were hurled back and forth. One man dropped to his knees and thanked God for his life. The rescuers explained that they had put the fan back in service 5 hr. after the explosion and that they had replaced blownout stoppings with brattice cloth, and after reaching the entry they were in they had closed each door as they came to it and waited awhile until the air cleared ahead before proceeding.

Then started the three-quarter mile walk to the outside. Reaction had set in. Some of the men could scarcely walk, and had to be assisted by the stronger ones.

They saw many evidences of the explosion in the cross-entry before they reached the slope, but the slope itself was a wreck. Cross-sets were blown out, there were falls from roof, a trip of cars half way up the slope when the explosion happened was wrecked and cars were hurled in every direction. Timbers were charred and covered with coke, and above all, that dank, sour odor of afterdamp.

They reached the surface just as the sun was creeping over the trees. Women and children with sunken eyes and drawn faces were huddled around little fires, waiting and praying that husbands and fathers would come out alive. When the men appeared at the mouth of the slope there was a rush from the women, each with a prayer that her man was among them. Those who didn't find their mates turned away silently weeping.

Doctors examined the men. Some were sent to the hospital in ambulances, others were sent to their homes.

Rescuers found 24 men in charge of the boss trackman in the pump room in the Second North, behind brattice cloth barriers. The pump was driven by compressed air, supplied by a pipe coming from the surface through a borehole. The men started the pump and were kept alive by the exhaust. All the men working in the room entries off the main haulage were killed by the force of the explosion.

John Hardy's body, burned to a crisp, was brought to the surface 24 hr. after the explosion.

It is true John Hardy paid the price, but what of the dozens of widows and scores of orphans who paid and will continue to pay through no fault of theirs?

My story is ended and the moral is, *don't let the explosion happen.*

# Many Refinements Render New Tipple Extremely Flexible[*]

### Rotary Dump, Balanced Shakers, Degradation Screens, Spiral Pickers and Swinging Booms Form an Unusual but Efficient Combination

THE TIPPLE recently constructed by the Spring Canyon Coal Co., Spring Canyon, Utah, differs from the ordinary structure of its kind, in numerous refinements for grading and otherwise preparing the mine product. Coal from the mines is delivered to it over a surface tramroad. Two tracks capable of holding about 40 cars, are provided for the loads and one track which will hold about the same number of mine wagons for the empties. The loads are fed to the dump by gravity from both tracks and are controlled by two squeeze blocks. These are of the type first designed by W. J. Elwood, but unlike the original blocks which were of wood operated by hand levers, they are built of steel and are actuated by compressed air at 100-lb. pressure. They are capable of holding securely 24 three-ton cars on a 2.5 per cent grade.

Loads are discharged by a full-revolving dump having a capacity of 5 cars per minute. After being dumped the empty cars go to the usual kick-back and gravitate onto the empty track. The hopper under the dump has a capacity of approximately 15 tons, and from it the coal is delivered to the shakers by a reciprocating feeder.

## SHAKER TYPE SCREENS USED

The screens are of the usual shaker type. They are 8 ft. wide and 72 ft. long built in two balanced sections. The pitch is 12 deg. 30 min., and the travel 6 in., the eccentric shaft making 100 r.p.m. The upper section of this shaker is shorter but heavier than the lower section. It contains the slack and nut screens, consisting of plates with 1⅝ and 3-in. circular perforations, respectively. The lower section contains plates with 4½, 6 and 8-in. circular openings extending from top to bottom of the screen in the order named. The shaker is so arranged that nearly all changes necessary for producing the different sizes of coal desired may be made merely by shifting levers. The most complicated of these alterations has been made in 2½ min.; most of the other changes can be made in less than one minute and some without even stopping the machine.

## FINE MATERIAL REMOVED

One of the refinements embodied in this machine is what is called a degradation screen. Just before the coal leaves the shaker it goes over a plate with 1⅜-in. circular perforations. This removes the fine material made while the coal is passing over the other screen openings. This fine coal goes into hoppers and thence onto the degradation conveyor which delivers it to the slack chute.

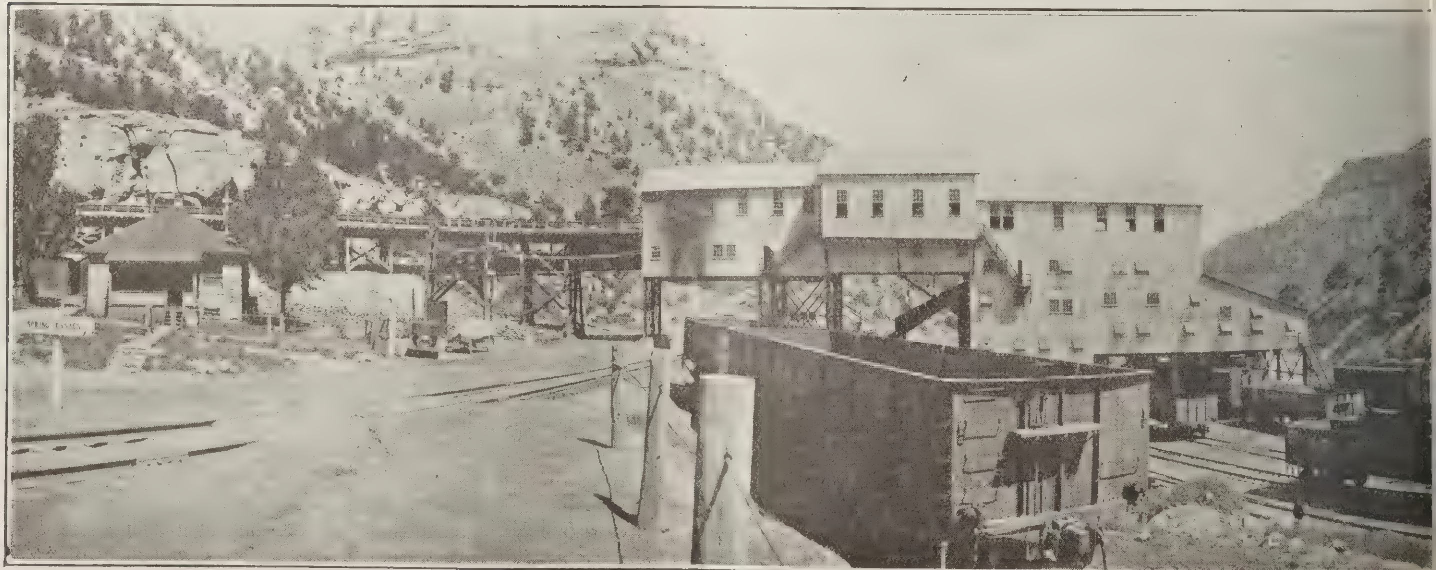
The different sizes of coal, excepting the slack, are delivered by the shaker onto three picking tables. These are horizontal for 24 ft. where they are hinged to form loading booms. Each picking table thus forms one unit of continuous conveyor.

Centrally located under the picking tables and below the floor, is the refuse conveyor extending at right angles to the tables. The impurities picked from the coal are dropped through openings in the floor and onto this conveyor, which discharges them into a bin of 100 tons capacity. From this bin the refuse is loaded into railroad cars through a gate.

Slack may be loaded directly into railroad cars through a chute from the hopper under the shaker, or it may be conveyed to the rescreener. Gates are provided by which all or any part of this material may be sent over either of these routes.

## CONSTRUCTION OF RESCREENER

The rescreener is a shaker 4 ft. wide and 16 ft. long provided with ¾-in. circular openings. The framework is of wood and the pitch is 5 deg. It is driven by eccentrics having a 5¾-in. throw and running at 143 r.p.m. This shaker is hung on 1x10-in. ash boards rigidly fixed at both the support and shaker ends, so that the spring of the boards permits the necessary



One of Utah's Newest and Most Complete Coal Preparation screen movement. The eccentric rods are also of ash, rigidly attached to the shaker. Movement of the eccentrics is likewise permitted by their resiliency.

---

[*] Abstract of a paper entitled "A Brief Description of the New Steel Tipple Recently Built by the Spring Canyon Coal Co., Spring Canyon, Utah," prepared by George A. Murphy, general manager of the Company, for the Rocky Mountain Coal Mining Institute meeting at Price, Utah, but not formally presented before that body.

Dust going through this shaker drops into a bin of 80 tons capacity from which it is loaded into railroad cars through a gate. A car may thus be loaded from this bin in two minutes.

### DISTRIBUTING SHAKER IN FOUR SECTIONS

Screened slack, or pea coal, from this rescreener is delivered to a distributing shaker driven from the same eccentric shaft that operates the screen, through eccentrics of the same throw, the two being balanced. The distributing shaker is divided into four sections, each occupying one quarter of its width. Each of these sections discharges its coal through a chute to a spiral. As the coal runs down on these spirals, the impurities or heavier materials move close to the center or axis, while the coal is thrown off the outer edge. The impurities are discharged into a conveyor and taken to the refuse bin, while the coal goes onto a boom and is conveyed to railroad cars.

Mention has been made of the refuse conveyor which runs under the picking tables. At a point near where this conveyor discharges into the refuse bin, pickers are stationed to remove lumps of coal that contain but little refuse matter. These are dropped into a crusher that discharges into an elevator-conveyor which delivers the coal to the main shaker in the form of slack and nut. The impurities are then taken out of the slack by the spirals, and are hand-picked from the nut on the picking table.

### HOW LOADING TRACKS ARE INSTALLED

Six loading tracks are installed as follows: No. 1 for loading lump coal into box cars; No. 2 for loading lump into open cars; No. 3 for loading egg and stove into either open or box cars; No. 4 for loading nut coal into open or box cars; No. 5 for loading mine run, straight slack, dust and pea coal into open cars, and No. 6 for loading dust and refuse into open cars. Still another track passes under the tipple, and is used for unloading sand and other material.

The combined picking table and loading boom on No. 2 track is fixed except that the boom end may be raised and lowered. It is so arranged that all or any part of the coal going over it, after passing the pickers, may be diverted to the box car loader boom serving No. 1 track. The Nos. 3 and 4 booms are of a modified swinging type. They are located on one side of the tracks, and when loading box cars are in a position parallel to them. When loading open-top cars, however, they are swung to positions such that they discharge directly over the center of the tracks.

All booms, five in number, are raised and lowered by electric hoists with pushbutton controls. Booms Nos. 3 and 4 are swung sidewise by means of trolleys on which the hoists are mounted. When loading box cars the Nos. 3 and 4 booms discharge into transverse conveyors that deliver the coal to the loaders. These conveyors are mounted on shafts near the ground. They are pushed into the car and removed from it by electric power.

Two extension-conveyor type box car loaders have been installed on tracks Nos. 1 and 3. The transverse conveyor and the foundation have already been built for the installation of a similar loader on track No. 4, but the machine itself has not yet been put in place.

### FIVE PUSHBUTTONS CONTROL MOTORS

All tipple motors are fitted with remote pushbutton controls, these latter being located in a central station in the weigh-room. Here five buttons control all of the motors. These buttons are so located that when operated successively from left to right, the several units of the tipple are started in the proper order.

There are a dozen or more pushbuttons located at various points about the tipple and used in stopping the machinery when necessary for shifting cars, changing the screens or any other reason. These buttons are so connected that when pushed they automatically stop all of the machinery that it is necessary to shut down in order to accomplish the work in hand and sound a gong in the central station. When this gong is rung twice from any of the pushbuttons, the weighman starts the several units in the proper order.

The capacity of the tipple is, 3,500 tons in 8 hr. and its cost, together with approaches, box car loaders, rearrangement of railroad tracks, etc., was approximately $260,000.

**Plants Is This One at the Big Mine of the Spring Canyon Coal Co.**

# Prompt, Efficient Action Saves Men and Mine from Fire

### Flames Are Attacked First with Hand Extinguishers and Men Are Withdrawn—Modern Equipment Is Great Aid—No Casualties

With the possible exception of an explosion the underground fire is probably the most spectacular of all mine disasters. Many fires, however, are "nipped in the bud" and extinguished before they can gain formidable headway. Such treatment necessitates prompt, careful and efficient action on the part of the mining organization, if serious property damage or even loss of life is to be averted. Such action saved the workings and the employees of the Kingston Coal Co., of Kingston, Pa., recently when a fire developed over night in one of its operations.

This fire broke out sometime during the night of Friday, May 15, 1925, in the Red Ash Bed, of the old Slope-Mountain Tunnel district which is tributary to No. 2 colliery. At this point a gang had been timbering on Friday afternoon. At the close of work in accordance with the usual custom the regular roundsman made his daily examination, finding nothing wrong. In fact, this roundsman was the foreman in charge of this particular job of timbering, so that in making his examination he inspected his own work.

On the following morning, Saturday, May 16, at about 7 o'clock, this roundsman found the timber set up the day before to be on fire. A nearby cog or crib was also burning. Notification was promptly given to the superintendent and foremen who immediately attacked the fire, the location of which is shown at *M* on the accompanying drawing, with hand extinguishers.

By this time, however, the volume of the smoke and gases had so increased that some of the men were overcome and had to be carried to a place of safety at *D* in the Eleven Foot Bed near the head of the rock slope to which point the foul gases had backed. This district is connected with No. 3 shaft and the fumes from the fire worked their way through other openings such as *L* and *N* and the caved area back of the fire thus gaining access to the No. 3 workings. Here they affected a number of men before they were able to make their escape. This necessitated rescue work at No. 3 shaft as well as in the immediate vicinity of the fire.

As soon as the nature of the fire was determined word was sent to No. 3 for the withdrawal of all men from the mine. It required some time to conduct a canvass of the total number of hands there employed and make sure that everybody was safe. In all about 40 men were more or less affected by noxious gases (chiefly carbon monoxide, CO) and smoke. Medical aid was given wherever necessary and no casualties were sustained.

Plans and preparations were immediately made to combat the fire. All men were withdrawn from the workings of No. 4 colliery which connected with the No. 2 workings and the production of coal was stopped in all mines of the company. The door at *N* was opened and the ventilating current from the Nos. 4 and 3 fans short circuited to pull direct through the caved district and away from the fire in the gangway. The chief object sought was to prevent the fire from spreading up the pitch into the outcrop.

With this change in the ventilation current the air moved down the rock slope from *D* to *R*. Next, by the use of brattice from *R* to *F*, it was possible to reach the door at *G*, which was kept closed. Good air was coming out the gangway at *H*, from the east side in the Red Ash Bed. A stopping (*H*) was accordingly erected at this point which cut off this air current.

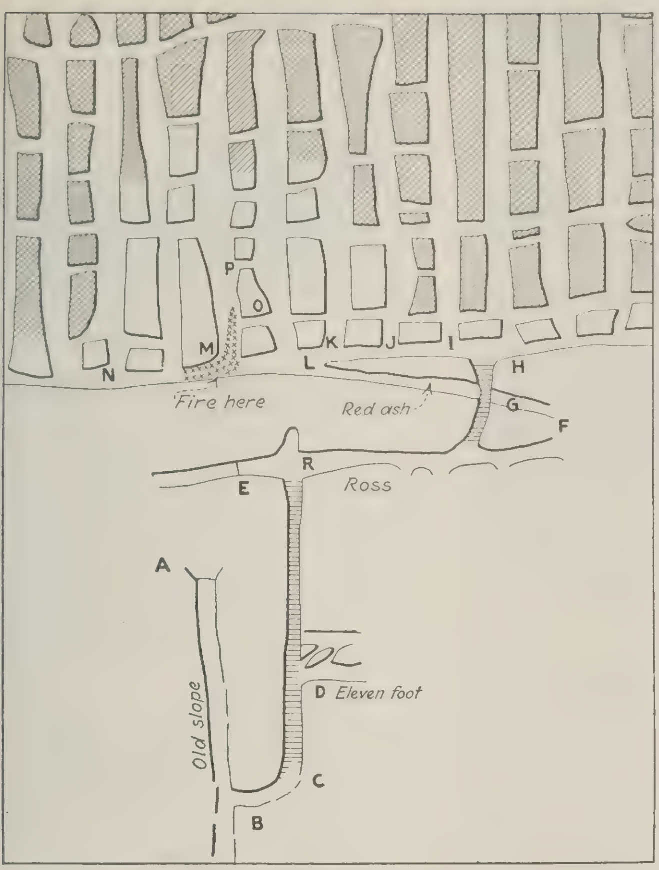
The fire was fought between the points *G*, *O* and *N* by men wearing oxygen-tank helmets. A relay station where the helmets were equipped with new tanks was established at *R*. On Saturday night an emergency blowing fan was installed at the mouth of the old slope, and the openings at *B*, *C* and *D* in this slope, the Bennett and the Eleven Foot beds were closed with stoppings. The brattices and other air current-control equipment between the points *R*, *F* and *G* were also tightened up so that the fire-fighting crew was ready for almost any emergency. Fortunately, however, no emergency demanding the use of this fan arose, and it was never necessary to place it in operation.

This emergency fan installed at the slope collar was direct connected to a steam turbine. It had a capacity of about 45,000 cu.ft. per minute. When the fire started, this machine was employed in the No. 2 power house supplying draft to the boilers. It was removed from its foundation at about 6:30 p.m., Saturday, May

**Hoist House Which Served as Cafeteria and Slope Mouth with Emergency Fan**

This building originally housed a steam hoist. When this was supplanted with the electric machine now used it left the rear of the building vacant. This made an excellent place for the cafeteria where food, fruit and coffee were served free to those fighting the fire which broke out almost directly below this building.

This fan was set up hurriedly to be ready to supply air in case of an emergency. When the fire was discovered it was supplying draft to the power plant boilers. It was removed from its foundation, transported about a mile, reset on mud sills and connected to a source of steam supply 2,000 ft. away.



**Plan of Workings Where Fire Occurred**

Only a portion of the Old Slope is here shown. This connects by somewhat circuitous passages driven through the rock with the measures in which the fire occurred. In fact the fire was almost directly under the hoist house serving the slope.

16, was transported over a distance of approximately one mile, was set up on a foundation of mud sills at the slope mouth, connected to a steam supply by about 2,000 ft. of 2-in. pipe and was ready for operation at 4:30 a.m., May 17. This is remarkably quick work considering the difficulties involved and the care that must necessarily be exercised in the setting and alignment of every high-speed machine.

Tests were constantly made on the composition of the air coming down the chutes at *H*, *I*, *J* and *K*. This gave a good check on the condition of the air and gases at the fire, the main object being to blanket the blaze as much as possible at the rear or at the points *N* and *O*. The plan of campaign was confined to a steady and continuous effort to prevent the fire from getting up into the caved and robbed area between its point of origin and the outcrop.

Water for fighting the fire was obtained through hose of the Edwardsville fire department, connected to the Spring Brook water main in the Borough of Courtdale. Several lines of this hose were laid over the surface and carried down the slope *A*. This means of obtaining water for direct application to the fire was augmented by a 2-in. pipe line. By 10 a.m., Monday, the fire was extinguished and on Tuesday work was resumed at all the collieries of the company.

Throughout the entire fight against this fire the company officials enjoyed the fullest co-operation from the state mining department, the U. S. Bureau of Mines, the mine rescue crews of neighboring coal operations and people of the vicinity. Thus, rescue crews came from the Glen Alden Coal Co., and also from the Lehigh & Wilkes Barre Coal Co. These men held themselves in reserve ready for any emergency that might arise, while their chiefs took council with those of the Kingston company who were actively engaged in fighting the fire.

Two and a half hours after the fire started, three women living in Courtdale nearby, arrived at the mouth of the slope, each carrying a big pot of hot coffee. This supply lasted until a cafeteria was put in operation in the rear of the hoist house. Sandwiches were furnished in large number by a local lunch room until they could be prepared by the operating force of the coal company. Fruits such as apples, oranges and bananas were also dispensed to the workers as well as pickles, olives and the like.

From start to finish this fire was fought in a scientific manner by the aid of modern equipment. Thus, gas testing machines, CO detectors, helmets and gas masks were freely employed. The loss of coal sustained was practically nil, the fire being confined almost entirely to the timbers and the gob. Much credit is due to the skill and hard work of the superintendents, foremen and assistant foremen as well as to the rank and file of the men, who exhibited marked loyalty and tenacity in fighting the fire.

### No Confusion or Disorder

One noticeable detail of this work was the perfect order which prevailed by common consent, also the excellent co-operation that existed between all parties. Throughout the entire progress of the fight there was no confusion, no loud shouting or obvious excitement. As upon many another similar occasion, however, some of the men became overzealous. Thus, at one period all the mine foremen were underground at the same time. This, however, was shortly after the fire was discovered and the foremen went in to warn and bring out the underground employees.

Of the 600 men employed in the slope and the No. 3 mine about 40 were overcome by gas and smoke and were brought out on stretchers. The remainder came out unaided by helmet men but in many cases assisted more or less by their fellows. In all about 12 helmets and 16 gas masks were employed. After the fire had been brought partially under control the masks were used far more than the helmets, and it became a task to provide canisters for them. These were procured from practically every source available in northeastern Pennsylvania. Some were purchased from nearby coal companies, some were borrowed and 50 were shipped in by express from Pittsburgh.

It looked for a time on Saturday morning as if this fire might prove decidedly serious from every standpoint. Fortunately, no human fatalities or even permanent injuries are to be recorded. Two mules, however, which at the time the fire started were in the higher workings of No. 3 mine succumbed to the action of the poisonous carbon monoxide. Several hundred rats did likewise. The mules appeared to have died peacefully in their stalls. The rats all left their holes and when found were lying flat on their bellies with all four legs extended as if they had simply given way under them.

The origin of this fire could not be determined definitely. The timber gang that worked on Friday used carbide lamps, and it is believed that the flame from one of them may have come in contact momentarily with some of the old timber being repaired. If this started the fire it doubtless grew from a smouldering spark in the evening to its formidable dimensions when discovered on the following morning.

# News Of the Industry

## Anthracite Miners and Operators Sit Back Awaiting Developments; Lewis Clings to Strike Weapon

Anthracite operators and miners settled back again this week and assumed the rôle of spectators in the hard-coal controversy after emphatically denying that peace proposals had been made by either side.

Without exception, operators interviewed during the week declared themselves in sympathy with the expressed policy of the negotiating committee to continue along the present lines in demanding that a new wage agreement carry with it provision for the avoidance of future suspensions of hard-coal mining.

An address delivered by John L. Lewis, international president of the United Mine Workers, in Shamokin Oct. 29 at a John Mitchell Day celebration brought little if any reaction throughout the region. The miners' spokesman declared in the course of his talk that the miners would not now or at any future time voluntarily relinquish the strike weapon. Philip Murray and Thomas Kennedy, vice-president and secretary-treasurer respectively of the international organization, also spoke at the meeting.

### Lewis Charges Gouging

Declaring that many anthracite companies also owned soft-coal mines, John L. Lewis charged that the hard-coal operators were trying to persuade people to use soft coal as a substitute for hard coal in order to gouge the public with both hands. The charge was made in a letter Oct. 28 to Major General Charles W. Berry, chairman of the New York State Coal Commission.

Samuel D. Warriner, chairman of the Anthracite Operators' Conference and the president of the Lehigh Coal & Navigation Co., refused at the company's New York office to reply to the Lewis statement. Only a few anthracite producers owned soft coal mines, Mr. Warriner said. Their total production from these holdings he estimated at not more than 1,000,000 tons a year. Inasmuch as little, if any, of the soft coal produced by anthracite operators came into the New York market he said, Mr. Lewis's statement was too "ridiculous" to warrant a denial.

The week brought with it several requests from washery operators to the Scranton district headquarters of the union for permission to operate their plants in order to supply coal to schools and churches in the region. Permission was granted to the Traders' Coal Co. to furnish a specified amount of anthracite for use in the Plains (Pa.) schools. The coal is to be washed from a refuse dump.

The other applicants for permission to operate are Reap & Murphy, North Scranton; Plymouth washery, owned by William Cook, of New York; Peckville washery, owned by Martin O'Toole, Scranton, and No. 14 washery, owned by Judge George W. Maxey and Attorney Frank Benjamin. These companies seek authority to supply coal to schools and churches in Plymouth, Plains, Hanover and Wilkes-Barre, all anthracite region cities. The applications will be acted upon soon by the executive board of District 1, United Mine Workers.

The Scranton union headquarters announced that circular letters are being mailed to local unions throughout the district forbidding the distribution of union funds in the local treasuries. It was reported that locals were dividing their funds among the needy members. This, according to President Rinaldo Cappellini, is a direct violation of the constitution of the union.

Reports from the lower field are to the effect that dredgers of river coal in the Schuylkill River are reaping a financial harvest as a result of the strike and demand created by local scarcity fears. In several places the coal is being loaded directly from scraper lines out of the river bed into trucks for delivery to consumers, without being screened.

Activities of mediators or peace bodies in the anthracite field, if any, are veiled with secrecy. Since the Rev. J. J. Curran's reported proposal to the miners, no others have been heard.

### Father Curran Calls on Governor

Father Curran spent several hours with Governor Pinchot at Harrisburg on Oct. 26 discussing the strike situation. Neither the Governor nor the clergyman, however, would later comment upon their meeting. Father Curran participated in the settlement of the 1902 strike and two years ago called upon the Governor just prior to his calling the conference of operators and miners to Harrisburg.

Statements attributed to a former New York fuel distributor telling of an alleged plan by Secretary Hoover for composing the anthracite strike have been denied vigorously by Mr. Hoover. He declared that he has made no such suggestion to anyone.

Directors of the Hazleton Chamber of Commerce last week discussed a suggested plan to bring about a resumption of negotiations between the striking anthracite miners and the operators, with chambers of commerce from other parts of the hard coal field participating. The matter was referred to a committee.

The efforts of the Hazleton Chamber of Commerce is in line with that of Scranton, which has been making efforts to have the wage negotiations resumed and the mine workers in the meantime return to work.

Independent operators at Pottsville have suggested to the striking miners that the coal strike may be considerably shortened if delegates to the convention which will pass upon the terms of settlement are elected in advance. It is estimated that the strike can be shortened nearly ten days by such action. After the committee of union leaders negotiates terms with the operators, it is necessary to refer the terms to a tridistrict convention. The election of delegates to such convention, heretofore, has been the cause of delay.

Miners stated they will comply with the suggestion if it does not conflict with any of their regulations. But they pointed out that nearly all locals will want to pass upon the merits of any suggestion to settle the strike and the sentiment can be expressed by instructions to delegates.

Operators said they merely made the suggestion to cut out some red tape when a final agreement shall be reached.

### *Industries Have Coal Stocks For Fifty Days*

Industrial activity climbed to a new high level in September, when 7.1 per cent more anthracite and bituminous coal was consumed in industry than in the month of August, according to the monthly report of the National Association of Purchasing Agents. The September consumption is estimated at 38,746,000 tons.

With bituminous production at capacity and with a tremendous slump in anthracite production from 8,845,000 tons during August to 39,000 tons in September, the estimated stocks of coal in the hands of industrial consumers on Oct. 1 was 65,012,000 tons. This is enough to last 50 days, based on the September rate of consumption.

# Scott Turner Named As New Director of Bureau of Mines

Scott Turner, of Lansing, Mich., has been selected as the new director of the Bureau of Mines. As Congress is not in session he has been given a recess appointment by President Coolidge. He is expected to assume his new duties Dec. 1. The White House statement announcing the appointment reads, in part, as follows:

"The appointment of Mr. Turner was made on the unanimous recommendation of the advisory committee from the mining industry recently appointed by Secretary Hoover and composed of representatives of the American Institute of Mining & Metallurgical Engineers, the American Mining Congress, the National Coal Association, United Mine Workers, and the American Petroleum Institute. In reporting to Secretary Hoover, J. V. W. Reynders, chairman of the advisory committee, wrote as follows: 'It is believed that the appointment of Mr. Turner will conserve the ability of the various divisional heads in the tasks to which they have been devoting themselves and promote the forward-looking plans which you have in mind for the extension of the Bureau's service in the economic and industrial development of the country.'"

### Called a Happy Selection

The committee's selection is generally regarded as a happy one. It is believed that Mr. Turner will bring to the Bureau a relationship with industry that could not have been secured otherwise. At the same time it has been made plain that the committee did not go outside of the Bureau for a director because of any lack of capable men on the staff. The President in announcing Mr. Turner's appointment did an unusual thing in bringing out this very point.

Mr. Turner when in Washington two weeks ago to confer with Secretary Hoover expected to be able to arrange his business affairs so as to take up his new duties Dec. 1. His confirmation by the Senate practically is assured, as the Michigan Senators are known to be well pleased with the appointment.

Mr. Turner was born in Lansing, July 31, 1880. He was graduated from the University of Michigan in 1902 and from the Michigan College of Mines in 1904. A sketch of his work as a mining engineer follows: Assistant engineer, Development Company of America, Tombstone, Ariz., 1904-05; field work, South Dakota, Montana, Oregon, California, Nevada, May-July, 1905; millman in Colorado, 1905; superintendent, San Pablo Gold Mining Co. and Pontiac-Panama Co., Province of Veraguas, Panama, 1905-06; examining engineer in Nevada for Detroit syndicate; miner Standard Mine of Federal Mining & Smelting Co., Mace, Idaho; Hecla Mining Co., Gem, Idaho, April-July, 1906; millman, Hercules Mining Company, Burke, Idaho, 1906-07; assistant editor with T. A. Rickard, *Mining and Scientific Press*, San Francisco, January-October, 1907; Superintendent Granny Gold Mining Co., Manhattan, Nev., October-December, 1907; engineer for F. W. Bradley, of San Francisco; smelter representative, Tacoma, Wash., for Bunker Hill & Sullivan Mining & Concentrating Co., and Alaska Treadwell, February-June, 1908; in Dawson, Fairbanks, and Nome, Alaska, with T. A. Rickard, June-September, 1908; engineer, Wild Goose Mining & Trading Co., Nome, Alaska, September-October, 1908; at Tacoma Smelter for F. W. Bradley, of San Francisco, 1908-09; chief assistant to mining geologist, U. S. Smelting, Refining & Mining Co., of Boston, 1909-10; mining geologist, Mammoth Copper Mining Co., Kennett, Calif., April-December, 1910; field work, tin mines, Cornwall, England, 1911; field work, Spitzbergen, J. M. Longyear, of Boston, June-August, 1911; general manager Arctic Coal Co., of Boston, in Norway and Spitzbergen; general manager for Ayer & Longyear, of Boston, in Europe; agent Arctic Steamship Co., 1911-16.

Scott Turner

He opened and operated for five years coal mines at 79 deg. 13 min. North Latitude on the Island of Spitzbergen (825 miles north of the Arctic Circle, on No Man's Land).

Mr. Turner started in the spring of 1916 for South America on mine-examination work for London banking interests; he spent the next two years in Peru, Chile and Bolivia, but when the United States entered the war he returned and signed on with the Navy for four years, receiving a commission as Lieutenant, senior grade. In January, 1919, he was placed on the inactive list, and at once went to Canada as chief field engineer for the Mining Corporation of Canada, Ltd., and its various subsidiaries. A few months later he was promoted to the position of consulting engineer to the corporation, which position he still holds.

## Seeks Soft Coal Bids

Bids have been invited on 28,400 tons of bituminous coal for the period from Dec. 1, 1925, to June 30, 1926, by the chief engineer of the Government Fuel Yards at Washington, D. C., up to 10 a.m. Nov. 16, 1925. Bids will be considered on either run of mine, nut and slack, or slack coal.

## National Coal Association Starts Research Program

How to combat the use of oil, how to help the consumer get greatest value out of his coal, how to "keep cool with coal" in the summer are the three studies which the members of the National Coal Association are going to study at once due to the activity of the association's research committee. Others will come along in due time after these have been studied.

As the result of a conference Oct. 14 at Washington, D. C., Walter Barnum, chairman of the committee, on Oct. 28 appointed sub-committees to study the three subjects which seem most to need the consideration of the research committee.

The subjects chosen are:

(1) Oil competition — methods of approach and valuable comparative data; M. B. Lanier (chairman), president, Munro-Warrior Coal & Coke Co., Birmingham, Ala.; J. B. Pauley, president, J. K. Dering Coal Co., Chicago, Ill.; E. L. Thrower, general manager, Warner Collieries Co., Cleveland, Ohio.

(2) Possibilities of servicing heating and power plants, including domestic heating plants, with report on (a) physical conditions as they exist and direct results that should be obtained; (b) indirect results likely as regards local and national good will; J. G. Bradley (chairman), president Elk River Coal & Lumber Co., Dundon, W. Va.; M. J. H. Jones, vice-president, Bertha Consumers Co., Pittsburgh, Pa.

(3) Increased summer coal consumption with special reference to artificial refrigeration and to systems for providing lower summer temperatures for office buildings, theaters, homes, etc.; Warren Blauvelt (chairman), president, Vigo Mining Co., Terre Haute, Ind.; Thomas De Venney, superintendent, Portsmouth Byproduct Coke Co., Edgarton, W. Va.

### Consider Seven Subjects

The committee had nineteen problems before it and felt that it was impossible to investigate all thoroughly and therefore favored concentrating on seven, among which are the three mentioned and the four following: (1) Preparation—washing and screening; (2) pulverized coal—methods, costs and adaptability; (3) distillation, (a) high and low temperature, (b) complete gasification of coal and possibilities of steady load factor resulting from condensation of this gas into motor fuel during low summer gas consumption, (c) commercial possibilities through concentration of plants near mines, high pressure transmission of gas, and oven load factor; (4) acid mine-water stream pollution.

The research committee recommended that it assist in the collection and creation of a library which will be a library of practical progress and actual new or growing accomplishment in any way connected with the production and use of coal rather than a library of text books of future and scientific value. It also favors the appointment of a trained specialized librarian who shall act as general secretary to the research committee.

## 142 Die in September In Coal-Mine Accidents; Rate Continues to Fall

Accidents at coal mines in the United States in September, 1925, resulted in the loss of 142 lives, according to information furnished by state mine inspectors to the U. S. Bureau of Mines. All of the fatalities were at bituminous mines, as work at the anthracite mines was suspended during September. No major disasters were reported during the month.

As the September output of bituminous coal was 46,817,000 tons the 142 fatalities represented a death rate of 3.03 per million tons compared with 3.32 in the previous month and 3.76 in September, 1924. No fresh-mined anthracite was reported, but a small amount was obtained from dredges.

During the first nine months of the present year 1,612 men have been killed by accidents at the coal mines throughout the United States, a death rate per million tons of 3.76 as compared with 4.48 for the same period last year. Reports for bituminous mines alone showed a nine-months fatality rate of 3.35 as against 4.28 for the corresponding months last year, a reduction of 22 per cent during the present year. The reduction in the death rate was due to the smaller loss of life in major explosions during 1925 as compared with 1924. For the anthracite mining industry the accident records for the present year from January to September showed a fatality rate of 6.19 per million tons as compared with 5.49 for the same months last year.

An analysis of the causes of the 1,612 fatalities in 1925 shows a reduction of 50 per cent in the per million tons death rate from explosions of gas or coal dust, including small and large explosions, the rate being 0.61 for 1925 and 1.23 for the nine-month period in 1924. Slight reductions in the fatality rate from electricity, haulage and falls of roof and coal also are shown. The rate for explosives shows an insignificant increase.

A comparison of the rates for the first nine months of the two years is shown by the following figures:

| | Jan.-Sept. 1924 | Jan.-Sept. 1925 |
|---|---|---|
| All causes | 4.476 | 3.761 |
| Falls of roof and coal | 1.841 | 1.794 |
| Haulage | .632 | .609 |
| Gas or dust explosions | 1.227 | .611 |
| Explosives | .174 | .184 |
| Electricity | .150 | .121 |

### West Virginia Mines Please Note

The Great South Wales Railway Co. announces that although less than two years have elapsed since the campaign for high-capacity wagons was begun by its general manager it is now possible to see the 20-ton wagons in considerable numbers working regularly on the routes serving the South Wales ports. — *The Engineer, London.*

## Output in North of France Higher in 1924

Coal output in the French departments of the North and Pas-de-Calais totaled 25,650,000 metric tons in 1924, as against 20,897,000 in 1923. The output for 1913 was 27,389,000 metric tons. The figures have been just reported by Consul Davis, Calais, to the Department of Commerce. Of the 1924 output 2,220 metric tons went to coke ovens and 18,952 to buyers of coal. Forty per cent of the miners are importees. Payroll personnel stood at 180,000, against 133,000 in 1913. Under the law of June 24, 1919, the workers are on an eight-hour basis.

The daily output per miner dropped from 1,333 gross kilos in 1893 to 1,058 in 1913, to 752 in 1922, and was 813 kilos in 1924. The wage cost in francs per net metric ton was 5.35 in 1893, 7.58 in 1913, 36.26 in 1922, and 41.10 in 1924, or in purchase power almost double the value of the 1893 wage and substantially higher than in 1913.

---

Mining and metallurgy are losing popularity as fields for technical careers whereas more men are entering the fields of civil and electrical engineering, according to the trend of enrollments just made public by Lehigh University, at Bethlehem, Pa. For years Lehigh University has been a mecca for students of mining and metallurgy, a condition that has been attributed by some educators to the proximity of the school to the anthracite field.

## Coal-Mine Fatalities During September, 1925, by Causes and States

(Compiled by Bureau of Mines and Published by *Coal Age*)

| | Underground | | | | | | | | | | | | Shaft | | | | | Surface | | | | | | | Total by States | |

# Pitfalls in Path of Coke Industry Show Need of Byproduct Association

**By Paul Wooton**

Washington Correspondent of *Coal Age*

With coke for domestic use heading for pitfalls similar to those encountered in 1922 and 1923 it has been suggested that this is a propitious time to organize the proposed byproduct association. Some 3,000,000 tons of coke was sold during the winter of 1922 and 1923, but few permanent customers for this fuel were made. Prices reached unreasonable levels and large quantities of metallurgical coke were put into the channels of retail distribution.

It has since been shown conclusively that gouging was not practiced by the coke producers. Their average sales realization during that period were no greater than those of the year before. They simply were not able to control prices once their coke got into the channels of trade. In the same way no effective steps were taken to keep shipments of foundry coke, unsuited for domestic use, out of the hands of the householder.

The same thing is in a fair way to happen again. The prices of beehive coke are rising sharply. Considerable quantities already are being sold for domestic use. The fear is expressed that this material is no better suited for household purposes than was that sold three years ago. The byproduct industry naturally is anxious to meet this situation. Such problems have been met with success in Great Britain by the association there. It is thought the experience of the British indicates what can be done here, particularly if the manufacturers of equipment could be included in the membership of the byproduct association.

### Co-operation Is Necessary

The present situation offers even a better opportunity to the coke producers than that of 1922, but it is apparent that little can be accomplished toward establishing standards of quality and their maintenance without co-operation among the byproduct producers.

Experiments conducted by the Bureau of Mines have demonstrated that coke properly prepared and mixed with fine anthracite provides a fuel with all the advantages of the larger sizes of hard coal and at a price frequently 20 per cent cheaper. Some of the coke being wished onto the domestic consumer is not suitable for household use. Ordinary metallurgical coke, even when broken down to egg, cannot be burned successfully in household equipment. Coking has been carried so far that the product is hard to ignite. When once well kindled, however, the fire is difficult to control. This resulted in such annoyance to householders three years ago that dealers in many instances were required to take back the coke they had placed in cellars.

It is believed to be entirely possible to produce a good domestic fuel in a beehive oven by the reduction of coking time. The problem of crushing beehive coke into sizes suitable for domestic use is a comparatively simple one. It also is suggested that if the beehive producers were to establish an association they could study better the needs of the situation and take the necessary steps to meet them.

While it is improbable that beehive operators would be interested sufficiently to undertake the creation of a permanent market for a domestic coke, such a course is regarded as essential to the future of the byproduct industry.

Just at this time, it is pointed out, an association of the byproduct manufacturers would find plenty to do. It could undertake an advertising campaign setting forth the advantages of coke as a household fuel. It could send out demonstrators to show consumers how to burn coke to best advantage in furnaces not designed for its use. It could issue some form of certificate of quality. While the association would have no direct control over beehive shipments, by keeping behind the local fuel committees it could be influenced in keeping unsuitable coke off the domestic market.

It always has been argued that a byproduct association is not necessary because the business at each plant is local, but had there been an association in 1922 the coke industry might not have missed the great opportunity offered then. To have an organization that would be able to prevent runaway prices during this emergency and keep up the quality of the product, would justify its existence for a long time to come, many think. Once formed and with the services of a capable secretary, it soon would be apparent that there are various constructive activities which such an association can follow in normal times. The headquarters of the British association at Leeds has proved to be one of the most valuable of the industrial clearing houses in the United Kingdom.

---

## *Put Out the Fire Before It Starts*

Joseph J. Walsh, Secretary of Mines, of Pennsylvania, has sent a letter to bituminous mine inspectors warning them of the approach of the winter season, "when the bituminous mines, by reason of the low atmospheric temperature, become extremely dry if not frequently moistened by watering. This gives rise to a dangerous condition. As the cold air enters the mine it slowly increases in temperature and consequently in volume, thus increasing its moisture-holding capacity. Thousands of gallons of water are each day carried in the air current from a single mine. This condition makes it necessary to use every precaution to prevent dust explosions. You are therefore instructed to be diligent in your efforts to have all the mines in your district properly and thoroughly watered or rock dusted as a preventive of coal dust explosions. Water or rock dust should be used freely in all dry mines throughout the winter. When applied as required by law, the coal dust is rendered inert to explosibility, and the propagation of flame cannot occur."

---

## Troops Withdraw from Oklahoma Coal Field

With the preparations by union officials to carry on their picketing activities with one man and three women to each squad, as allowed in the injunction issued by federal Judge R. L. Williams at Okmulgee, state troops, which have been on guard in the Henryetta district for the last several months, were reported as being withdrawn. The withdrawing of the guards came as a surprise, in that it was officially announced in Oklahoma City that only four officers and no enlisted men had been on active strike duty in the fields around Henryetta for the past several weeks.

Union miners at a mass meeting in Okmulgee last week decided to accept a loan of $200,000 which had been offered by unions outside of the state, it was reported. The fight has not been lost yet, according to a union statement.

Predictions made by coal operators that the injunction would result in many idle miners returning to work seems to be correct, as larger working forces are reported at mines Nos. 7, 10 and 12 in this area, over near Hartshorne.

---

## Jones & Laughlin to Have 422 Coke Ovens

The Jones & Laughlin Steel Corporation, Pittsburgh, Pa., has placed a contract for the construction of another battery of sixty coke ovens at its byproduct plant in Hazelwood, Pa. The value of the contract is close to $1,000,000. The ovens will be installed by the Wilputte Coke Oven Corporation. The new addition will bring the total number of ovens at the Hazelwood byproduct plant to 300.

The corporation, in addition, now has under construction at its Aliquippa works 122 Becker type ovens, and with the completion of the Hazelwood addition it will have a total of 422 ovens with an estimated capacity of 1,957,000 net tons of coke per year.

---

## To Discuss Standardization

E. A. Holbrook, chairman of the Mining Standardization Correlating Committee of the American Engineering Standards Committee, has tentatively called a meeting of the former, to be held in New York City Nov. 11. For several months routine business of the committee has been handled by correspondence, but the point has been reached where a thorough discussion by the full committee is necessary to a decision on some important subjects which will be announced later.

## Two Big Union Mines in Northern West Virginia Strike Zone Close Down

One of the most serious blows that was dealt the United Mine Workers of America in its effort to retain the organization in northern West Virginia occurred over the week-end, when mines Nos. 1 and 2 of the Simpson Creek Colleries Co., at Galloway, Taylor County, 12 miles west of Grafton, among the largest mines in the Fairmont field and the biggest plants to work with organized labor, were closed down indefinitely, throwing 500 union miners out of work with the approach of winter, according to press reports. The company is officered by persons being affiliated in an official way with the Y. & O. Coal Co. of Cleveland, where the concern has its headquarters.

Incendiaries are believed to have burned down a tipple at No. 6 mine of the Gilbert-Davis Coal Co. on Scott's Run, at Randall, near Morgantown, in the early morning of Oct. 28, causing a loss of $5,000. Either grease or oil was used to saturate the structure before the match was applied, it is believed. The mine, it is said, was operated on a co-operative basis, but union miners' officials say that the company is signed up as a union company. A new tipple will be erected.

Non-union coal production is on the increase in the region. More non-union coal was produced Oct. 28—1,792 cars—than on any day since the strike started, April 1. A new non-union coal loading record was attained on the Monongah division of the B. & O. on the same day when 961 cars were produced. In the first half of the week the non-union mines of the region produced 5,156 cars of coal compared to 4,790 cars in the corresponding period of the previous week. On the average there were 208 non-union and 17 union mines at work in the region in the first half of the week.

By the use of the distress warrant the Consolidation Coal Co. was recently awarded possession of 23 houses by Justice of the Peace W. H. Billingsley in Fairmont. The houses are located in Ida May, Carolina, Baxter and other mining towns. The company did not resort to the usual means of eviction, but took the landlord's proceedings to have tenants quit the premises. It is reported that the union will appeal the cases. Observers say that usually it requires less time to obtain the houses under a distress warrant than under the other type of procedure.

---

The U. S. Bureau of Mines is planning investigations into causes of accidents by falls of roof and coal, in co-operation with the mining department of West Virginia. R. M. Lambie, chief of the Department of Mines of West Virginia and the Bureau of Mines will detail investigators who will conduct tests in West Virginia mines with a view of decreasing accidents of this character. According to officials of the Bureau, strength of roof and timbering is not the only factor involved, but details of mining methods and administration enter into the situation.

## Western Shippers Oppose Reconsignment Boost

E. M. Platt and H. J. Trossen, speaking for a committee of coal shippers, opposed an increase in reconsignment charges from $2.25 to $2.70 on coal and coke to points in Western Trunk Line territory, at a public hearing held Oct. 27 in the Western Trunk Lines committee rooms in the Union Station, Chicago. The carriers took the protest under advisement. Mr. Pratt is chairman of the traffic committee of the American Wholesale Coal Association and Mr. Trossen represented the Old Ben Coal Corporation, Chicago. The other members of the committee were: Roscoe B. Starek, president of the Chicago Wholesale Coal Shippers' Association; G. H. Merryweather, Waubun Coal Co., Chicago; Abe Mitchell, Mitchell & Dillon Coal Co., Chicago; and James Anderson, of C. M. Moderwell & Co., Chicago.

## Repeal of Taxes Urged

Allan H. Willett, for the National Coal Association, on Oct. 27 urged before the House Ways and Means Committee the repeal of the capital stock tax, the stamp tax on stock certificates, and also the retroactive features of the Revenue Act of 1924 dealing with reorganization of companies.

## *Oil-Electric Locomotive Makes Debut*

What is said to be the first oil-electric locomotive purchased in this country went into service Oct. 24 in the switching yards of the Central of New Jersey R.R. near New York City following tests which revealed that the cost of operation was about a fifth of that for the ordinary steam locomotive and that in performance the new engine was revolutionary. It weighs 60 tons. The Long Island R.R. has contracted for a 100-ton locomotive of the same type, to be put into service soon, according to George Doubleday, president of the Ingersoll-Rand Co.

Mr. Doubleday said that the sale of the two new locomotives marked the advent of a new era in railway operation, for not only is the cost of operation greatly reduced through the use of crude oil as fuel, but great speed is possible without sacrifice of load. The locomotives are being produced by Ingersoll-Rand, in conjunction with the American Locomotive Co. and the General Electric Co. A similar locomotive has been produced by the Baldwin Locomotive Works and the Westinghouse Electric & Mfg. Co.

Mr. Doubleday announced that four locomotives of the new type were in course of construction and four more are to be built. Five trunk line railroads have requested the company to submit propositions regarding the locomotives, and inquiries have come from other carriers.

## Bethlehem Mines Will Join 1917 Wage Group In Pittsburgh Region

The Pittsburgh district movement to reopen mines on the 1917 wage basis grows slowly but steadily. The Bethlehem Mines Corporation is planning to open its mines at Marianna, near Bentleyville, on the low rate. It is understood that the company has already asked for property protection from the sheriff of Washington County and has erected a strong 36-ft. fence around its properties. The mines in that section, known as the Pigeon Creek Valley, has been closed for some time. The section is a union stronghold.

Union officials declare that all previous attempts to operate below the union wage in this section have met with failure. They recall that three years ago when an attempt was made to operate a mine at Cokeburg Junction with non-union workers the situation became so serious that it was necessary to have a unit of the Pennsylvania National Guard encamped nearby.

According to an unofficial report in local coal circles, the Lilley Coal & Coke Co. is working 12 men in its recently opened Lilley mine in the Monongahela Valley under the 1917 scale.

The Pittsburgh Coal Co. announces that it has more men working under the 1917 scale in the Pittsburgh district than ever before. The 198 men working at the Midland mine, near Houston, also is the highest since the pit opened three weeks ago. There as a total of 674 men on the rolls of the company in that district. In two weeks the company placed as many men at work at Midland as it required six weeks to enroll in the Youghiogheny Valley mines. Banning No. 1 has 205 men and Banning No. 2 mine, 271.

Production of coal in the Pittsburgh district for the week ended Oct. 25, as reported by the railroads, amounted to 345,552 tons, from 83 mines, compared with 341,483 tons from 82 mines in the preceding week.

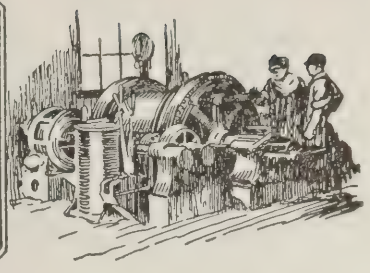
## Belgian Miners May Strike

Belgian coal mine operators having refused demands for a 5-per cent increase in wages last week, the miners threatened to strike this week. The producers contended that it was already impossible for the industry to meet foreign competition. Meanwhile, the government, in hope of stimulating the market, proposes to purchase 50,000 tons of Belgian coal monthly for the railroads. This coal heretofore has been furnished from the German reparation shipments at an actual loss to the government.

## Union Officials Quit

Frank Ledvinka, for six year president of Sub-district No. 5 of District No. 6, United Mine Workers, has resigned. His resignation became effective Nov. 1. His is one of the half dozen resignations of officials in that district and probably is the result of the ineffectiveness of the miners' officials' efforts to unionize the section.

# Practical Pointers For Electrical And Mechanical Men



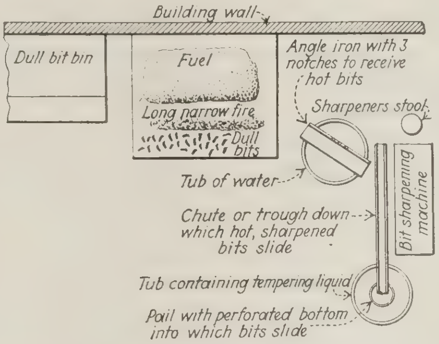
## "Factory Methods" in Mine Shop Make Bit Sharpening More Scientific

With the extended use of the mining machine or undercutter has come the necessity of quickly and accurately sharpening the bits. In this operation the coal mine shop can, in large measure, emulate the example and imitate the methods followed in any factory where a long series of duplicate or at least similar operations are to be performed.

At the No. 8 mine shop of the Old Ben Coal Corporation at West Frankfort, Ill., the sharpening of undercutter bits has been reduced almost to a science. In other words, this routine work has been so planned that there is extremely little lost motion, the bits moving through the sharpening operation in practically a continuous stream, only two men being required for this work.

In this shop the bits for thirty-five undercutters are regularly sharpened. These are passed one at a time through a Sullivan bit sharpener which not only properly shapes the bit but rolls it to a point or an edge. Three shapes of bits are used in the mines of this company—the pick point, the chisel point and the fishtail. The pick point is used for hard, the chisel for medium and the fishtail for easy cutting.

Formerly, machine bits were sharpened by hand on the anvil. Later the power hammer came into use and lastly the bit sharpening machine. In the shop in question, two men now sharpen as many bits as formerly required six blacksmiths—four on the day and two on the night shift. Furthermore, the sharpener rolls each bit to shape without loss of metal, whereas the old trip-hammer method cut some steel away at each sharpening with the result that bits now last approximately twice as long as formerly. There is, therefore, a saving in labor, a saving in steel, the bits last longer, and since they are more nearly uniform in shape the stresses imposed on the undercutter are likewise more nearly uniform, repairs are less and the power consumption is smaller.



Building wall
Dull bit bin
Fuel
Long narrow fire
Dull bits
Angle iron with 3 notches to receive hot bits
Sharpeners stool
Tub of water
Chute or trough down which hot, sharpened bits slide
Bit sharpening machine
Tub containing tempering liquid
Pail with perforated bottom into which bits slide

**Arrangement of Bit Sharpening Equipment**

The heater faces the furnace and holds his tongs in his right hand, placing the heated bits in the notches of the angle iron between the furnace and the bit sharpener. From here they are picked up as required, put through the machine and dropped into the chute or trough down which they slide into the tempering liquid.

In the sharpening process the bits, or rather their points, are first heated. This is done in a furnace about 4 ft. square with the tuyere pipe extending from end to end about a foot from the front edge. This leaves a front and a rear hearth. On the front hearth are piled the bits to be sharpened while the rear hearth serves as a storage for fuel, which, in this case, is small sized coke. The fire is thus about 6 in. wide and 3½ ft. long. Into this fire the bits are placed point down and as fast as one is removed another is added so as to keep a supply always ready for the machine.

One man does the heating and one the sharpening. As the bits are taken from the fire each is laid in a rectangular notch in one leg of an angle iron that passes across the top of a tub of water at the right of the sharpener. They thus lie in the most convenient position possible for him to grasp with his short, curved-nose tongs. The sharpener quickly places a hot bit in the jaws of the machine, gages it as nearly as possible and starts the ram carrying the shaping roller. As a rule one stroke of the ram is sufficient to sharpen the bit although sometimes two or even three strokes are required.

After the bit has been sharpened in this way it is removed from the machine and dropped into a trough down which it slides into a bucket with a perforated bottom. This bucket is immersed almost to its rim in a half barrel of "tempering fluid" sunk into the floor of the shop. This tempering fluid is merely water to which a strongly alkaline laundry soap has been added. About 1½ bars of this soap are used per day. This liquid is replenished from time to time as it boils away under the action of the hot bits. The arrangement of furnace, sharpener and the like is shown in the accompanying plan.

In many respects this process of bit sharpening reminds one of that of heating rivets in construction work. The bits move in a fairly steady stream from the hearth, through the fire, through the sharpener and into the compound at the rate of from 12 to 14 per minute. As a rule the heater and sharpener change off. That is, one will shovel a pail full of bits from the dull-bin, pile them on the hearth, heat and pass them to the man who operates the sharpener. When these have been run through the machine the men change places. At each change the bits in the tempering pail are drained and dumped into a barrel containing sharp bits. This process goes on until all the bits dulled during the preceding day or night have been sharpened.

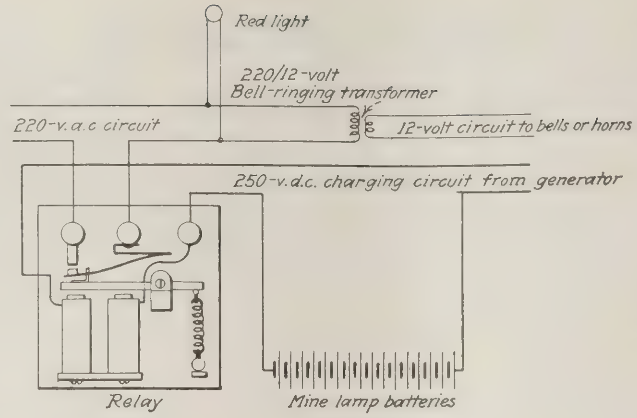
---

## Signals Tell When Charging Current Fails

When the direct current used to charge the batteries of electric cap lamps fails at the Union Pacific Coal Co.'s mines, a signal quickly carries this information to the lampman or watchman. By means of a relay, alternating current is supplied to red lights located at the power house, the lamp house and even at the lampman's home. In some in-

**Relay Operates Signals**

The battery-charging current normally holds the relay contacts open. If the direct-current circuit is broken, alternating current is supplied to the signal lamp and a bell or horn.



stances these signal lamps are supplemented by a buzzer or horn.

As long as direct current is flowing through the relay its magnet coils are energized but as soon as the direct-current circuit is broken the relay closes its contacts upon a circuit which supplies alternating current to the red light signals and also to a bell-ringing transformer which furnishes low voltage to noise-making alarms.

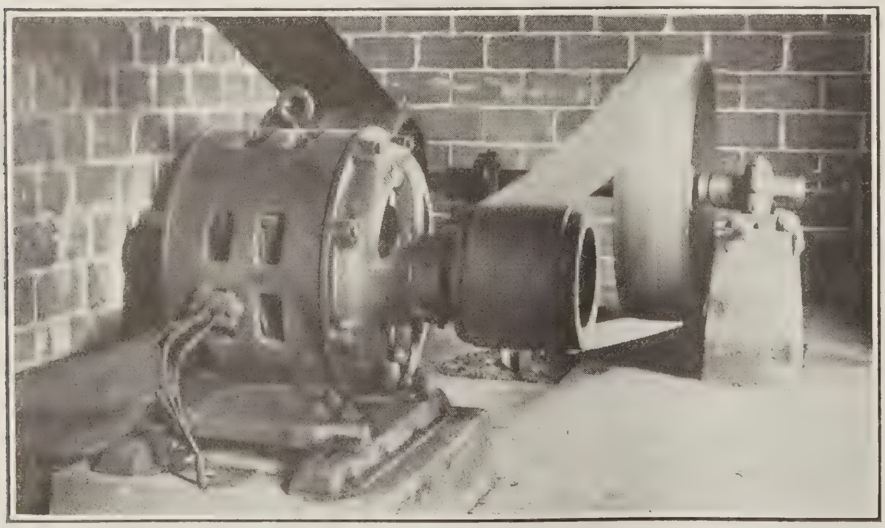
Thus a complete charge of the miners' lamps is assured when morning comes and there is no delay or complaint regarding the number of hours that the cap lamps will remain lighted when in the mines.

## Long Take-Ups Are Used on Fan Countershaft

In certain instances countershaft belt drives have proved unsatisfactory for mine fan service. In many cases no way was provided for increasing the belt center distance in order to compensate for stretch of the main belt. A spliced belt had to be used and there was the frequent expense of cutting and shortening, yet the belt was seldom at the correct tension.

A countershaft drive which has proven highly satisfactory is that of the Pike County Coal Corporation, at Petersburg, Ind. Here a 14x6-ft. mine fan is driven at 59 r.p.m. by a 690-r.p.m. motor. This large reduction is obtained with a 16-ft. belt center between the fan and countershaft. The feature which makes this installation successful is the use of long-movement take-ups on the bearing pedestals supporting the countershaft.

This adjustment, combined with that provided by the motor base, gives the installation a flexibility which makes it possible to use endless belts. The fan pulley is 96 in. in diameter and its mating pulley, on the countershaft, 26 in. The other countershaft pulley, 44 in. in diameter, is driven from a 14-in. motor pulley. The belt-center distance between the motor and countershaft is 9 ft. This makes a compact installation which, as compared to a single-reduction belt drive, has but one objection: three extra bearings must be lubricated and maintained.

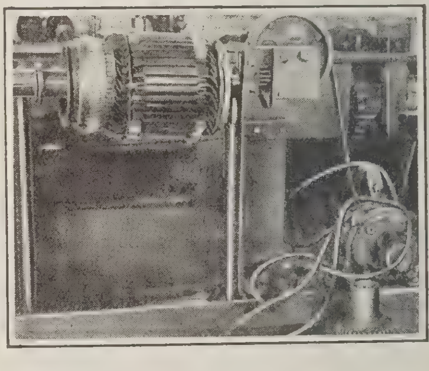


**Fan Drive of the Pike County Coal Corporation**

This compact countershaft drive is satisfactory because long-movement take-ups are used on the three bearings supporting the countershaft. The use of these take-ups makes it practical to employ endless belts. The motor operates at 690 r.p.m. and the fan at 59 r.p.m. The large speed reduction is obtained with but 16 ft. between the centers of the fan and countershaft.

## Armature May Be Wound and Banded on Same Stand

In electrical repair shops at coal mines many kinds and types of armature stands for use in rewinding these parts have been devised. The accompanying illustration, however, shows a device of this kind by means of which an armature can not only be rewound but rebanded as well. This particular machine was designed and built by the electrical repairmen in the shop of the Valier mine at Valier, Ill.

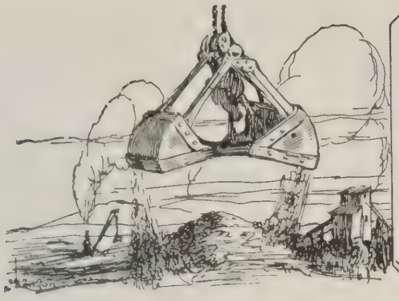


**Almost Ready for Banding**

When rewinding of this armature is completed the little motor near the floor may be started, the tightener pulley forced down and the armature banded without removal from the stand.

It consists primarily of an armature stand not unlike those of the ordinary variety except that both standards are mounted on a common base which is extended to take a small motor. This is belted to a nest of back gears which can be connected to the armature shaft if desired. The armature may thus be power-revolved whenever such a movement is wanted. The belt from the motor ordinarily hangs loose but may be tightened by means of an idler pulley.

By means of this device, after an armature has been rewound in the ordinary manner it may be banded without removing it from the stand. This arrangement thus saves the time necessary to remove the armature from the winding stand, transfer it to a lathe and set it up ready to receive the banding wire. Furthermore, this machine relieves the lathe from the banding operation and permits it to perform the work for which it was primarily intended.



# Production And the Market

## Bituminous Coal Market Gains Strength As Demand for Prepared Sizes Increases

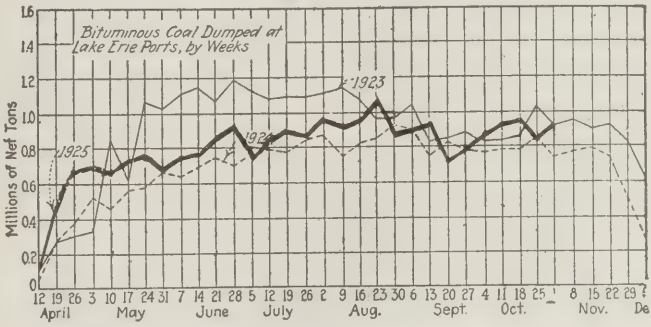
Increased strength characterizes the soft-coal market as the demand for screened coals gains momentum, domestic consumers continuing to turn to such substitutes for anthracite with the end of the strike nowhere in sight. Mine-run is beginning to pick up some in sympathy but is still comparatively quiet. Steam-coal business is showing more signs of life with most of the railroads taking full quotas on contracts and industrial consumption on the upgrade. Coal is moving through the Cincinnati gateway in record-breaking volume for this season, 15,314 cars having passed through last week, 3,124 destined for the lakes. Congestion in the latter traffic has caused a car shortage on the Louisville & Nashville R.R.

The comeback of West Virginia smokeless is a notable feature of the market, demand being so strong that there has been a scarcity in some centers, and prices, of course, show a steadily upward tendency. Noticeable firmness is in evidence even in New England, though there has been no marked improvement in demand. Unwilling to pay the high figures asked for Pocahontas, many Midwest dealers who hitherto have been specializing in smokeless are turning to high-grade southern Illinois coals. Screenings are finding a ready market. Cold weather has been bringing buyers out in force.

Central Pennsylvania low-volatile coals, especially egg and stove sizes, are in strong demand in Eastern markets, and at advancing prices. A large number of mines in this field that were closed down during the summer have resumed, but a good many are still idle. Inability to obtain prompt shipments of low-volatile in some instances has caused a marked increase in the sales of medium- and high-volatile grades. The heavy demand for prepared coals is making the disposal of slack somewhat troublesome.

Pea coal having almost reached the vanishing point and buckwheat rapidly moving into the scarce category the anthracite market is practically a thing of the past. Coke, which was the first substitute for hard coal to which consumers turned, now is a difficult article to obtain and the price shows a skyward tendency.

Bituminous coal output during the week ended Oct. 24 is estimated by the Bureau of Mines at 12,104,000 net tons, the first time the 12,000,000 mark has been exceeded since last January. This compares with 11,770,000 tons produced in the preceding week.



Anthracite output in the week ended Oct. 24 totaled 13,000 net tons, a decrease of 4,000 tons from the previous week.

*Coal Age* Index of spot prices of bituminous coal on Nov. 2 stood at 181, the corresponding price being $2.19, compared with 178 and $2.15 the week before.

Dumpings at Lake Erie ports during the week ended Nov. 1, according to the Ore & Coal Exchange, were: Cargo, 873,665 net tons; steamship fuel, 45,760 tons—a total of 919,425 net tons, compared with 850,696 tons in the preceding week. Hampton Roads dumpings in the week ended Oct. 29 totaled 405,873 net tons, against 437,190 tons in the previous week.

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Midwest Trade Responds to Cool Wave

A snowstorm and a substantial drop in temperature last week did the Midwest coal market a world of good. Dealers are clamoring for Illinois and Indiana domestic sizes, and in some cases operators with coal in transit or with car numbers were able to obtain a slight premium.

There is some doubt in the minds of southern Illinois operators as to the advisability of increasing circular prices 25c. a ton Nov. 1. Some of them, it is said, will advance 6-in. lump and 6x3-in. furnace to $3.50, while others will remain at the $3.25 level, though nothing definite has been decided at this writing. Producers of high-grade domestic coals in Indiana and in other parts of Illinois are holding back circulars until they find out what the Franklin County operators are going to do. They will, of course, be very largely influenced by the policy of the Franklin County people.

Eastern coals, which have been cutting quite a figure in the Chicago market during the past year or so, proved to be unusually scarce last week. The West will not pay the prices for smokeless prepared coal that the East is willing to pay, and dealers who heretofore have been specializing in smokeless coals are now falling back on high grade southern Illinois fuels. The Western market is willing to go as high as $5.50 or $6 for Pocahontas lump and egg, but no higher. Pocahontas mine-run shows signs of strength and moves freely at $2.50. It is expected that an advance will take place before many days. High-volatile coals from West Virginia, which were offered in the Chicago market a little while back at around $2.50 for prepared sizes, are now quoted at $3.25@$3.50.

The steam coal market continues fairly satisfactory. High-grade southern Illinois and high-grade Indiana Fourth Vein 2-in. screenings are finding a ready market and a good demand. The bigger industries show an inclination to buy, fearing a possibility of labor difficulties in the Illinois and Indiana fields arising out of the use of loading machines. A satisfactory volume of screenings is being sold and at reasonably satisfactory prices. The less favored coals of Indiana and Illinois are having hard work in finding a market and continue to drag.

Nobody shows any particular interest in hard coal. The public is buying coke as never before, and it is likely that when the anthracite strike is settled anthracite operators will encounter some difficulty in getting back their old trade. Outside of a few cars moving to branch offices of operating companies, practically no hard coal is in the Chicago market.

Seasonable weather continues to show an increased movement of domestic sizes in the Carterville field and also in the Harrisburg district, especially of lump and egg, but the nut sizes and steam are slow and at various points in the last week a slight car shortage developed. The movement

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Nov. 2 | Oct. 26 | Oct. 19 | Nov. 3 |
| Index ................... | 181 | 178 | 176 | 171 |
| Weighted average price.. | $2.19 | $2.15 | $2.13 | $2.07 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and, second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

of coal by the carriers is unusually slow. Working time is from four to five days a week at the shaft mines and railroad tonnage is reported fair. There is no change in prices.

In the Duquoin district four and five days a week is the working time at the mines that are operating, but the only size moving well appears to be lump. Egg and nut are slow, with no railroad tonnage except at one mine. Strip mines in this district are working regularly. The Mt. Olive field shows remarkable activity, having almost full working time, a market for all coal and an unusually heavy railroad tonnage moving. Working time is four to five days a week.

In the Standard field there is little change. Coal is still selling at about cost of production and there is no unusual demand for any particular sizes excepting 6-in. lump, and this is scarce because there is no market for the smaller sizes. Steam is slow and railroad coal is reported light. All mines carry "no bills." Working time ranges from three to four days a week. Prices are unchanged.

Domestic business in St. Louis continues to show improvement on account of seasonable weather. The movement of coke locally became good this week; anthracite and smokeless are still slow, dealers in St. Louis having an abundance of anthracite on hand, although smokeless is pretty well cleaned up. Carterville is beginning to move fairly well but the demand continues for middle priced coals. Standard is beginning to get into its own with the poorer classes. Apartments and schools are pretty well filled up. Country domestic is fairly good on all sizes. Local wagonload steam continues to show improvement. Carload is fair but is not equal to the supply. Country steam is fairly good. Several hundred cars of coke have been shipped out from the St. Louis switching district ovens in the last week. Some of these orders are for Buffalo, Toronto and points farther West. This call is for chestnut coke, which takes the place of anthracite. No change in prices.

## Heavier Movement from Kentucky

Demand and movement are stronger in Kentucky this week and prices are better. Eastern Kentucky has advanced until practically no block coal is under $2.85, and best grades are quoted as high as $3.50; lump and egg running $2.25@$2.75, and nut, $2@$2.25. Mine-run is unchanged at $1.40@$1.65, but screenings are a shade weaker at $1.10@$1.35 due to larger production. In western Kentucky 6-in. block has advanced to $1.90@$2.25; lump, $1.75@$2; egg, $1.75@$2; nut, $1.25@$1.50; mine-run, $1.20@$1.50 and screenings, 70c.@$1.10. Steam coal is weaker as a result of small nut and screenings being in larger supply. Car shortage is developing in eastern Kentucky.

Railroad consumption is running very heavy, while utility and plants show no real indication of a let-up.

Eastern Kentucky mines appear to be very busy, with a lot of good business in hand, a heavy movement to the lakes, and a steady increase in coal moving into sections affected by the anthracite strike. Western Kentucky is gradually increasing tonnage moving to the North and Northwest.

## Fresh Burst of Activity in Northwest

Colder weather over the Northwest contributed to a fresh burst of activity in the Duluth-Superior coal market last week. All the docks operated full time in loading out cars for transmission to points over a wide area including Minnesota, North Dakota and northern Wisconsin. So brisk has been bookings by retailers in the last few weeks that many are taking on fresh supplies.

Industrials are ordering steam coal more freely and inquiries from public utilities are broader than for some time. Some of these buyers have been contracting further ahead recently. On the whole, dock operators are more optimistic regarding the outlook.

Last week forty-one cargoes of coal were unloaded at the docks and ten more were en route. Free bituminous coal on the docks is now placed at 3,700,000 tons and stocks of railroad coal are figured nearly 2,000,000 tons additional.

No panic over the possibility of an anthracite shortage has as yet developed. Dealers are experiencing a steadily expanding trade in Pocahontas and other smokeless fuels and it is figured that supplies of those fuels coming forward will be found ample to cover all requirements.

A brisk and increasing demand for bituminous coal is reported by the managers of coal docks in Milwaukee, and a sort of scramble demand for the comparatively small tonnage of anthracite still in stock. The increased call for Pocahontas consequent upon the shortage of anthracite has kept the price firm and on the upgrade. Dealers are looking for a further advance in prices at the mines, but no change has been made here yet in the rates that have prevailed for several weeks. The weather is unseasonably cold, and consumers now are eager to fill their bins.

## Southwest Sees Rebound

A return of cold weather has brought fresh joy to coal operators in the Kansas field, and in more modest degree to the entire Southwest. Oklahoma and Arkansas, because of a market reduced by labor trouble and rumors of labor trouble, do not share commensurately with Kansas in the seasonal activity. A brief period of warmer weather permitted a readjustment between domestic and industrial grades, but, with the resumption of heavy domestic demand due to the early arrival of below freezing weather, a screenings surplus again has begun to accumulate. Consequently, while the price of $4.75 for Kansas lump has become more firmly established, with some operators quoting it as high as $5, there is an increasing tendency to shade the list quotation of $2.35 for Kansas screenings.

Arkansas semi-anthracite lump quotations are fairly stable at $6@$6.50 a ton, with several big operators in the Arkansas field still keeping their mines idle.

McAlester (Okla.) lump is quoted at $7; nut, $5.50; screenings, $2.25. Henryetta (Okla.) lump is $5; nut, $4.25; screenings, $2@$2.25. A slowly but steadily increasing production is reported from Oklahoma.

The demand for the domestic lump and steam size coal in Colorado is in excess of the production, which is causing operators some difficulty to the extent that nut is slow to move. The situation probably will materially improve, as cold weather has set in in Kansas and Nebraska. Colorado anthracite mines are working at full capacity and the bituminous and lignite fields are operating about 90 per cent. There are no changes in current prices on coal since last week.

The Utah coal market continues dull, due to weather conditions. The railroads have been taking more coal for steam purposes than normal for the season on account of the heavy crops which must be moved, but heating plants are not taking much coal yet. The car supply is ample, but this is due to the light demand for coal rather than the ability of the railroads to furnish necessary transportation facilities. Prices are steady and the labor situation is good. Domestic lump, the next grade to straight lump, is becoming more popular.

### Smokeless Situation Mixed at Cincinnati

The smokeless situation in Cincinnati still proves a hard nut to crack. November circulars of the larger Pocahontas producers show one company's price $5 for lump and egg "to our recognized contract customers," another's $5.50 and a third's $6. In the face of all this mine-run marks time.

Under the influence of a car shortage on the L. & N. due to congestion at the lakes, southeastern Kentucky block has stiffened up to $2.75@$3.25 for coals that formerly had a range of $2.50@$3. Egg is $2.50 and 2-in. $2.25. Mine-run is about in the same range as last week and the slack commands $1.25@$1.35 for anything that is good. The Chesapeake & Ohio avoided a car shortage by obtaining 1,000 cars from an Eastern road on a mileage per diem basis. Still the congestion at the lake ports primarily and the jam at the gateways is getting rather serious in view of the fact that navigation gets its last fling about Nov. 10.

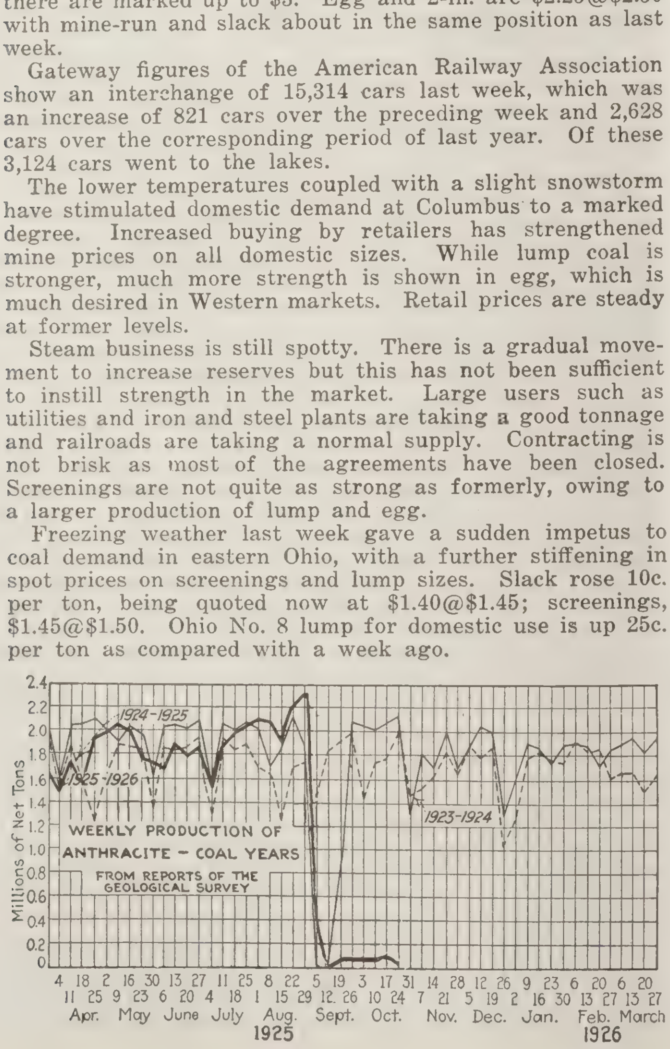
The price of West Virginia coals has started to move upward. One large competitor of a Logan County company that fixed an arbitrary of $2.50 on lump has broken away and has boosted the November price to $2.75. Kanawha also has refused to be led and some of the leading coals there are marked up to $3. Egg and 2-in. are $2.25@$2.50 with mine-run and slack about in the same position as last week.

Gateway figures of the American Railway Association show an interchange of 15,314 cars last week, which was an increase of 821 cars over the preceding week and 2,628 cars over the corresponding period of last year. Of these 3,124 cars went to the lakes.

The lower temperatures coupled with a slight snowstorm have stimulated domestic demand at Columbus to a marked degree. Increased buying by retailers has strengthened mine prices on all domestic sizes. While lump coal is stronger, much more strength is shown in egg, which is much desired in Western markets. Retail prices are steady at former levels.

Steam business is still spotty. There is a gradual movement to increase reserves but this has not been sufficient to instill strength in the market. Large users such as utilities and iron and steel plants are taking a good tonnage and railroads are taking a normal supply. Contracting is not brisk as most of the agreements have been closed. Screenings are not quite as strong as formerly, owing to a larger production of lump and egg.

Freezing weather last week gave a sudden impetus to coal demand in eastern Ohio, with a further stiffening in spot prices on screenings and lump sizes. Slack rose 10c. per ton, being quoted now at $1.40@$1.45; screenings, $1.45@$1.50. Ohio No. 8 lump for domestic use is up 25c. per ton as compared with a week ago.



A much improved demand is perceptible from almost all quarters, the chief activity being in domestic grades. Due to heavier shipments of smokeless from West Virginia mines to the East, Pocahontas is quoted at Cleveland at $6.25@$7 f.o.b. mines, as compared with $5 ten days ago, and retailers are said to be having difficulty in getting prompt delivery. Steam inquiries likewise are more active, and the railroads are reported to be taking 100 per cent on contracts.

### Increased Strength at Pittsburgh

The Pittsburgh district coal market has grown much stronger in the past week. Current output seems to have been well absorbed by previous purchases, making a market in which there is a fairly large volume of inquiry and offerings scant indeed. Inquiry is largely from the East and North and may be considered typical of demand for an anthracite substitute, as it runs largely to egg size, something the district ordinarily has little call for.

Curious results have followed from the demand running in this line. Egg coal has brought up to $4 and may be quoted at $3.75@ $4 as the going market of the past few days, whereas 3-in. lump has been bringing only $3.50@ $3.75. Ordinarily the Pittsburgh district does much in 1¼-in., which used to be the ordinary domestic size, and in 2-in., but when operators can get such high prices for egg they refuse to quote on 1¼-in. and 2-in.

Slack coal naturally has gone off, with the heavier shipments of egg and lump, and is now $1.15@$1.25 for steam and $1.25@$1.35 for gas, and weak at that. In general the market is up fully 25c. in scarcely more than a week and if demand continues so insistent prices on some grades may advance farther. Gas coal has not been able to maintain its premium.

Mines that operated through the summer are now running full and some additional mines have started.

The bituminous trade at Buffalo is in rather demoralized shape. Slack is hard to sell, but the producers of Pittsburgh lump and Allegheny Valley mine-run are putting their prices up 25c. or more, apparently just to see if they can get it. As a rule the shippers here say they cannot sell at the advance, but it may prevail for all that.

### Demand Light, Prices Firm in New England

The market in New England is noticeably firmer. Advances in prices on mine-run as well as prepared are being well maintained and it is clear that anything approaching steady demand will mean a still higher level, especially for the smokeless coals. A curtailment of mine-run to the Hampton Roads piers relieved the pressure and to such an extent was it carried out that a few of the agencies were without spot tonnage beyond contract commitments. There also has been some exchange of coal between shippers in order to clear cargoes, but for the most part the available supply is more than ample for current requirements.

On No. 1 Navy standard Pocahontas and New River the range has been lifted to $4.85@$5.10 per gross ton f.o.b. mines for mine-run, with slack continuing to sell at about $1.30@$1.40 per net ton f.o.b. mines. Notwithstanding better prices there is no marked improvement in demand; buying is very sparing.

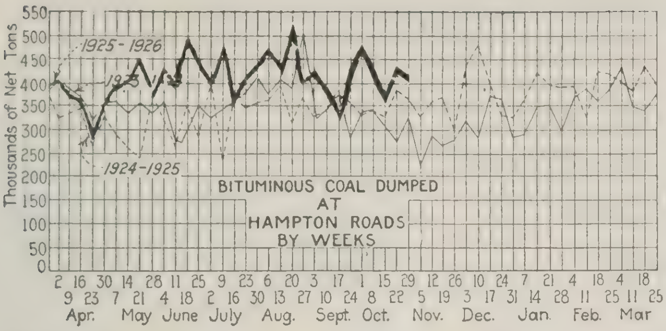
For delivery inland from Boston and Providence there is scattering inquiry, but latterly the mine-run smokeless coals have acquired a reputation for an undue proportion of slack, owing, the buyer surmises, to the heavy demand for screened coal. Prices on cars are $6@$6.25, with the probability of an advance within a few days to $6.50.

Lump and egg are being held firmly at $6.50@$6.75 for Pocahontas and New River, subject to some delay in shipment. From central Pennsylvania the range of price on the desirable coals is 50c.@75c. higher, retail dealers being willing to pay that much more because delivery is reasonably prompt and the all-rail tariff is so much less.

For Pennsylvania mine-run there is only light demand. Prices have improved, but the smokeless coals still have the call in this territory.

### Heavy Movement to New York

New York industrial buyers are calling for heavy shipments of mine-run coal, the retail trade is taking an increasing tonnage, both screened and unscreened, and the bituminous producers whose mines are in operation have



about all the business they can handle. Low-volatile operators equipped to ship prepared sizes similar to domestic anthracite are turning away orders for this part of their output, although the disposal of slack is causing them some trouble.

As high as $7@$8 a ton is being quoted for low-volatile egg and stove sizes by central Pennsylvania operators. Unsized lump from which the slack has been screened is bringing $5.50@$6.50, f.o.b. mines. Medium-volatile grades are from 50c. to $1 under these figures. High-volatile egg and stove range in price $4@$5 at the mines, and there has been a marked increase in demand recently because of the scarcity of other grades.

Retail dealers are buying an increased tonnage of mine-run, but many consumers have not yet started taking this coal. Cold weather will force them into the market sooner or later, if the anthracite collieries remain idle, and their requirements, added to those of industrial consumers and the railroads, bid fair to create a shortage unless the supply is materially augmented by the reopening of idle mines.

Domestic demand for soft coal is putting a little stir in the trade at Philadelphia, but steam business is as quiet as it has been for weeks past. Each day sees an increase in the domestic use of bituminous of all low-volatile grades. A strong demand is setting in for all mine-run coals of a lumpy nature. Now that the byproduct coke has been almost entirely absorbed there is a strong demand for the beehive product.

Sized gas coals are pretty well sold up, although this has produced a considerable amount of slack which is not moving with the speed that the producers would like. Buying for railroad account of all fuels is moderate and the situation at tide is only ordinary.

The soft-coal situation in Baltimore remains flat and uninteresting in so far as regular mine-run coals are concerned, although reports from the various offices indicate that prepared sizes continue strong and active, with a further advance in price likely. Latest quotations on these coals are from $5.50 to around $5.65 per net ton. The coke situation is unchanged, with prices at the highest level they have been for a long time. The export situation has gone absolutely dead, with no records of coal shipments since Oct. 13.

Demand for domestic coal at Birmingham continues to show improvement and spot buying during the past week has amounted to considerable tonnage. Most all business placed was by dealers who had nominal stocks which were depleted by the rush of retail orders following the several cold spells of late, and from community centers and small towns in the territory. The mines have taken on sufficient business to move their output without delay in connection with contract business, on which deliveries have not been materially increased so far. All spot buying was for prompt shipment.

Buying of steam coal is on the increase and there is some scarcity of the high-grade washed and mine-run product, creating a stiffer demand for medium and lower grades, which are moving better than before for some time. Utilities have cut their requirements to a low figure on account of greater activity at hydro-electric plants; the ginning season is about over, and demand from other seasonable industries has slackened considerably, but this loss has been more than offset by healthier and heavier industrial requirements. The stiff demand for all grades of coke has taken a large tonnage of fuel off the commercial market, foundry quotations having gone to $6@$6.50 per ton during the past week for spot shipment, with a very active call of wide range for all domestic sizes.

## Hard-Coal Substitutes High and Scarce

Even No. 1 buckwheat is no longer available in the New York wholesale market, except for a relatively small amount in the hands of wholesalers. Orders are no longer being accepted by the companies, it is reported, as they already have commitments for practically all the tonnage remaining in the stocking plants. Reserve stocks of other sizes in the hands of the larger producers were exhausted some time ago, and even the speculators have little left.

Some retail yards still have considerable anthracite left, but the bulk of it is steam sizes. The larger coal is being sold in small quantities to regular customers or held for emergencies. Buyers usually are required to take an equal or greater amount of soft coal or coke with each delivery of anthracite.

It is only a question of a short while now until the average dealer will have nothing but substitutes to offer. It is becoming difficult to obtain prompt shipments of the most desirable substitutes, namely, coke and sized low-volatile bituminous. The demand has been so great for several weeks that producers are sold up and in many cases oversold. Besides, the price has gone to a level which buyers hesitate to pay.

Because of these conditions the buying of screened high-volatile and medium-volatile coals has been greatly stimulated of late and prices have advanced.

Coke is now selling for $9@$10 at the ovens and is practically unobtainable for prompt delivery.

What little independent buckwheat is to be had commands around $5, mine basis, for line shipments. Loaded boats of this size in New York harbor are being held at $6.75@$7.25 alongside.

Not a great deal of pea and buckwheat arrived at Philadelphia during the week. The storage stock of pea seems to have almost reached the vanishing point and the price is $12@$12.50, with some at $13. Storage buckwheat is fast moving into the scarce class at $3, with an increase almost a foregone conclusion.

Dealers who delayed purchasing coke as a substitute now find it almost impossible to purchase. Wholesale prices range $9.50@$11.50 at the ovens and retail quotations $17@$18 per net ton, but the demand from consumers is not at all brisk.

The situation at Buffalo grows more complicated day by day, though more in people's minds than otherwise. So many anthracite consumers have the idea that there is a coal famine because they are not able to get large sizes that the city authorities sent a man to the mining regions and bought a thousand tons for distribution in small amounts at schedule prices to those who were without any. The offering of all sorts of substitute fuel goes on. Coke leads, for there is a great demand.

There is no change in the Baltimore hard-coal market, both dealers and operators apparently being satisfied to mark time for the present at least.

## Connellsville Coke Market Suffers Reaction

The Connellsville coke market gained in strength up to early last week, when something happened. Prices went up to a range of $8.50@$9—$9.50 is said to have been obtained from some Eastern jobbers on run-of-oven coke. Prepared coke, broken by various means, seems to have commanded $1 a ton over run-of-oven, or $9@$10.

Inquiry continued to diminish, leaving the market in rather slack condition at this writing, quotable on the basis of last sales at $8.50@$9.

Blast furnaces continue out of the situation, but have marked up pig iron prices $1 a ton in anticipation of higher coke cost when contracts for the present quarter expire.

Foundry coke has gotten into some demand and has made a market, at $9@$9.50.

# Foreign Market And Export News

## Foreign as Well as Inland Trade Improves in British Market

The general situation in the Welsh steam coal trade is regarded as more favorable, but the improvement cannot as yet be considered as marked. The last two months were undoubtedly the worst in the steam coal trade for many years, and it was hardly to be expected that conditions would remain so bad for an indefinite period. There is no prospect of prices improving for the present, but it is all in favor of the Welsh steam coal industry that there should be some recovery of exports, even if only of a partial character, and inquiries seem to be coming forward from all the customary Welsh markets.

Inland trade, both domestic and industrial, also is reviving. A little contract business is being done, chiefly for locomotives, for delivery over the next two months, there still being unwillingness to do business for twelve months owing to the possible effect of the government subsidy and as to what may happen when the subsidy is withdrawn.

There is a change for the better in the Newcastle-on-Tyne coal trade, and the outlook may now be described as comparatively good. Inquiries for all classes of coal have broadened and cover more extended periods instead of being merely from hand to hand as hitherto. While bookings of the collieries extend into November and also December and some are able to see their way clear to the end of the year. Contract business consists mainly of small gas coals.

Output by British mines during the week ended Oct. 17, according to a special cable to *Coal Age*, totaled 4,715,000 gross tons, compared with 4,685,000 tons in the preceding week.

### Belgian Market Unchanged

The situation in the Belgian coal market is unchanged from last week; industrial coals are rather weak and domestic coals generally firm. Prices remain the same; anthracite continues to advance while in industrial coals the tendency is lower. In consequence of decreased foreign exchanges, there is renewed competition both French and foreign, particularly the former. Stocks are diminishing, even in the Borinage basin. The demand for coke and for ovoids is slightly better.

### General Tone Is Firmer At Hampton Roads

The market at Hampton Roads last week was stronger, demand being more active, particularly in domestic coal. New freight rates to New York and New England helped coastwise business also, and bunker trade was brisk.

Prices were strengthened and inquiries more frequent. A slight increase was seen in foreign shipments. The situation in car lots is reported better, and some mines that were practically inactive for several months have begun increased production. Feeling in the trade is more optimistic.

### French Market Improves

A slight improvement is noted in the demand for industrial coals in the French market. For domestic coals the situation is very favorable, a scarcity of sized products being feared if the winter is severe. Despite the increase in costs of 2 fr. 50c. per ton brought about by most of the French mines having decided to revert to the old rate of 40 per cent for the cost of living bonus, the North and Pas-de-Calais collieries have raised prices of industrial coals only 40 to 80 centimes a ton. Bituminous peas have been reduced from 109.20 fr. to 107.60 fr. Although domestic coal prices have been increased in the same proportion as the Belgians—i.e. from 5 to 12 fr.—prices are still lower than those of competitors.

During the month of September the O.H.S. received from the Ruhr 758,500 tons of reparation fuels, including 502,100 tons of coal, 227,000 tons of coke and 29,400 tons of lignite briquets. This tonnage does not include the deliveries of German fuels purchased on the free market and credited to the reparations account.

During the first thirteen days of Oct. the O.R.C.A. received from the Ruhr 93,396 tons of coke. The price of indemnity coke has been reduced from 145 fr. 95c. to 144 fr. 75c. including all charges of the O.R.C.A.

# News Items From Field and Trade

## ALABAMA

The Birmingham Coal & Iron Co., Birmingham, of which L. E. Boyetta is president, will soon begin the expenditure of about $100,000 on tenant houses, tipples, washers, screens, etc., to increase the capacity of the coal mines to about 1,000 tons per day.

The Joseph A. Holmes Safety Association, which has a large number of chapters in the mining camps of the Birmingham district, will disseminate information and instruction regarding mine-rescue and first-aid work among the membership by having outstanding mining men and engineers write papers on various subjects germane to such work. These papers will be printed and circulated each month among the members of the local chapters, where they will be read and discussed. The first of these papers will be prepared by S. L. Morrow, a prominent industrial man, formerly chief engineer of the woodward Iron Co., who will discuss "What a miner should do after a fire or explosion in the mine."

Estimates of coal production in Alabama for the present year are more than 19,000,000 tons. For the first nine months of the present year the car loadings and other reports show an output of 14,564,000 tons. Output by months so far this year is: January, 1,641,000 tons; February, 1,583,000 tons; March, 1,726,000 tons; April, 1,450,000 tons; May, 1,645,000; June, 1,555,000; July, 1,575,000; August, 1,625,000; September, 1,764,000. As production is on the increase the figures for October, November and December are expected to be large.

## ILLINOIS

Sale of the assets and stock of the Southern Gem Coal Co., which includes large coal mines in southern Illinois, was ordered Oct. 19 at Cairo, by Federal Judge George W. English, upon a petition setting forth that the receivers, into whose hands the company was given more than a year ago, have been unable to meet a $75,000 monthly maintenance expense. The mining property, located in Franklin and Jefferson counties, was valued at more than $1,500,000.

Six hundred coal miners were given employment Oct. 26, when the Saline County Coal Corporation's No. 3 mine, at Harrisburg, resumed operations after a long shutdown. In Saline County eleven large mines are now in operation.

Six senior students of the mining engineering department of the University of Illinois, under the direction of Prof. I. M. Marshall, spent the week of Oct. 25-31 visiting the southern Illinois coal fields. They visited, among others, the following mines: Union Colliery Co., Dowell; Black Servant Coal Co., Elkville; Mine Rescue Station, Benton; Orient Mine No. 2, West Frankfort; Nason Coal Co., Nason; United States Fuel Co., Middle Fork, near Benton; St. Louis Smelting & Refining Co., Collinsville; St. Louis Coke & Iron Co., and National Enameling & Stamping Co., Granite City, as well as the National Lead Co., Salt River, Mo. This is an annual trip required of students before graduation in mining engineering.

The Peabody Coal Co. opened its Mine No. 51, at Andrew, Oct. 16, with two hundred miners employed. The mine normally has an output of 1,200 to 1,400 tons of coal daily. It has been closed since February, 1924.

Mine No. 7 at Kincaid opened Oct. 26.

The Standard Coal and Coke Corporation, a Delaware corporation, has purchased the Sangamon Coal Co.'s mine, North Grand Avenue, East Springfield. The indicated purchase price was $270,000. The Sangamon company's mine has been considered one of the best in the Springfield district.

Operations at Valier mine, Valier, have been resumed after a shutdown of several weeks.

The West Virginia mine, at Herrin, has been closed down since Oct. 8. This mine is one of several which entered into the recent consolidation of six mines near Herrin by the Standard Coal & Coke Corporation. The West Virginia mine was owned by Wallace Brothers.

The East Mine, Lincoln, which had been closed since early last spring, resumed operation Oct. 26. It is believed that full production will go forward through the winter.

## INDIANA

Joseph Stephenson, 58 years old, superintendent of the Little Betty mine, near Linton, and his son, William Stephenson, 28 years old, were killed Oct. 20 in a gas explosion in the mine. A gas pocket was ignited. The body of the son was recovered by mine rescuing crews an hour following the explosion, but the body of the father was not found until three hours later. The two men were inspecting the mine when they came on the pocket of gas, the explosion being set off by the carbide lamps carried by them.

After an idleness of more than two and one-half years, the American mine No. 2, in the Bicknell field, the second largest coal mine in Indiana, will be opened soon. The mine is capable of producing 6,000 tons of coal daily and employs 600 men. Nine other mines in the Bicknell field have been idle almost as long as the American mine.

The Wasson-Pocahontas Coal Co., of Vincennes, has filed a preliminary certificate of dissolution.

## IOWA

John Ruth, of Hurley, S. D., has purchased the Lockwood coal mine, at Carbon, and will operate it.

## KENTUCKY

The Chesapeake & Ohio R.R. on Oct. 23 asked the Interstate Commerce Commission for authority to purchase three miles of coal railroad operating between Dinwood and Lackey, in eastern Kentucky, for $106,143.

Tim B. McAuliffe, of Louisville, who formerly operated the McAuliffe Coal Co., with a mine in western Kentucky and jobbing office at Louisville, has returned to the coal trade. He is now with the Louisville office of the Nashville Coal Co., after some months in advertising work. McAuliffe at one time was with the Southwestern Fuel Co. and also connected with the Southern Coal Co.

K. U. Meguire, of the Harlan Coal Co., Louisville, jobber and operator, was one of the incorporators of the Morris Plan Industrial Bank, which is getting ready to start operations in Louisville soon.

A. H. Stepp has become manager of sales for the Hawley-McIsaac Coal Co., Madisonville, a concern with several strip as well as some shaft mine operations. Formerly he was in charge of the Louisville office of the Southern Coal Co., going to Madisonville some months ago.

Tom Finn, formerly with the Southern Coal Co., Memphis, who has been selling out of the Louisville office for some time, has been sent to Nashville, Tenn., as manager of the sales office at that point.

The Banner Fork mines of Henry Ford, at Kentenia are down again, according to Abner Lunsford, who was in Cincinnati recently. About six weeks ago the 16-ft. axle of the drum snapped. As nothing of this kind was kept in stock the mine had to shut down for a couple of weeks until a new axle was obtained. When the new one was set in position it apparently worked excellently for a short time when it too let go. The break came in almost the same relative place as the former one snapped.

After having disposed of his holding in the mines at Darbyville, Va., in which he and Ralph Bartlit, of Cincinnati, were interested, Charles Thompson, long identified with mines and mining in southeastern Kentucky, announced that he had accepted a position as general manager for the group of Harlan mines controlled by Judge Hall, of Harlan, which include the Three Point Mining Co., the Ellis Fork Mining Co. and the Lena Rue Coal Co.

J. J. Fluck, formerly chief engineer of the Elkhorn Piney Coal Mining Co., and later superintendent of the Weeksbury mines of that company, has accepted a position with the Youngstown Sheet & Tube Co. as superintendent of the Dehue (W. Va.) mines, vice L. E. Scholl, who resigned recently.

## MINNESOTA

The new briquet plant of the Berwind Fuel Co. at Superior is now operating at full capacity of 800 tons daily. The company is making its product from Pocahontas screenings. The Stott Briquet Co.'s plant, also at Superior, is operating at capacity. Its product is made from anthracite dust.

The Zenith Furnace Co., at Duluth, is looking forward to a record season in production and sales of domestic coke on this market. The company accumulated a substantial supply in anticipation of a spurt in demand for it as an anthracite substitute. Shipments of its coke have been made over a wider area so far this season.

Both St. Paul and Minneapolis are taking up the strict enforcement of the smoke nuisance ordinances, the city officials feeling that the emergencies which caused a letup in their enforcement have passed.

## MISSOURI

The Busy Bee Mine, at Huntsville, is still idle, though it is reported that several of its miners have bought capital stock in the company in order that it might be placed in operation to give employment. The owners proposed leasing the mine to the miners who had been employed there. The miners conferred with Arch Helm, district president of the United Mine Workers, about the lease, and while Mr. Helm approved the lease, he said he could not approve the working conditions, according to George Hepple, secretary of the miners.

A deal has been consummated between the owners of Mine No. 11 at Higbee and former employees of the shaft for the purchase of the property. It is understood that more than one hundred shares of stock were sold in the mine. The shares were $200 each. The name Moniteau Coal Co. has been chosen. Officers are as follows: James Rankin, president; Fred Laight, vice-president; A. E. Humphrey, secretary-treasurer. These with Joe Bradley, Mike Marietta, Charles Moore and Charles Deering constitute the board of directors.

## OHIO

Suits aggregating $20,000 for wages have been filed by 281 miners of the Franklin mine of the Cleveland & Western Coal Co., at Stewartsville. A separate petition was filed in each case with Justice Louis M. Shores. Recently the coal company filed suits in common pleas court against the same miners for $10,000 damages. The company alleges the men had several times closed the mine by illegal strikes, causing heavy monetary loss.

Upon petition of John E. Jones, who claims to be a creditor of the company to the extent of $63,000, the Athens National Bank has been named receiver for the Canaan Coal Co., which has several mines near Athens. The property of the Canaan Coal Co. is roughly valued at $500,000. The mines have been closed for six months and one of the mines was partly wrecked by a gas explosion recently.

The Capitol Motors Co., owner of the building where the defunct Southern Ohio Coal Exchange had its offices, in Columbus, has brought suit against ninety-three former coal companies and individuals to collect rent in the sum of $5,440. The operators' association is now in the hands of a receiver. The suit is brought to collect against the former members individually.

Within ten days after the Hughes Coal Co., Cincinnati, went into the hands of a receiver trustee in bankruptcy John Glaser was able to announce the payment of 7 per cent in cash to the creditors. It is understood that C. H. Hughes, chief stockholder of the company, has agreed to give notes to those holding claims so that the firm will pay out 100c. on the dollar. Most of the creditors have agreed to this and it is expected that the firm's affairs will be wound up in short order.

So bad was the jam of cars during the week of Oct. 18 between the Cincinnati gateway and the unloading docks at the lake ports that J. M. Dewberry, head of the coal and coke department of the Louisville & Nashville Ry., wrote to Cincinnati distributors asking that all coal that could be routed through the Louisville gateway be headed in that direction.

A petit jury in U. S. District Court at Cincinnati on Oct. 27 returned a verdict for the plaintiffs in the breach of contract suit of Edward F. Gerber et al. as F. & R. Coal Co., Pittsburgh, Pa., vs. the Borderland Coal Sales Co., Cincinnati. The amount of the verdict is $10,263.13. This was the second trial of this case, the first having resulted in a verdict for the defendant for $27,177 on a counterclaim. This was set aside by U. S. Circuit Court of Appeals. The amount sought by the defendant in its counterclaim was admitted to be due by the plaintiffs at the second trial and is taken into account in the verdict given in their favor.

An electric power deal between the Southern Ohio Electric Co and the United Light & Power Co. has been closed whereby power plant development in the Athens section of the Hocking Valley will be much increased. The United Light & Power Co., a large concern operating quite a few power plants in the Middle West, has taken over the Southern Ohio Electric Co., which operated a large power plant at Floodwood. The two power companies will join in serving all of the southern Ohio mining district. The production of coal for the generation of power will be largely increased with the building of new units to the plant.

Cincinnati wholesalers are beginning to see the advantages to technical enlightenment in fuel engineering. Two are enrolled in the combustion and steam engineering classes of the University of Cincinnati in the persons of Armour Sizer and Elmer Wierhake.

Four large mines in the Baily Run field which were put out of commission recently by the burning out of a high-tension power line have been placed in operation, giving employment to about 800 miners.

Owners of small mines in the vicinity of Athens have started work to supply domestic users in nearby districts.

**Towboat "Hecla" of the Hillman Transportation Co. Operating on the Monongahela River**

A number of the mines of the Hillman Coal & Coke Co. are bounded on one side by the Monongahela River, on the banks of which the tipples are located. Consequently the coal may be shipped by water or by rail. Here is one of the stern-wheel steamboats that tow barges of Hillman coal downstream.

Farmers are driving to the mines for their winter's supply and there is quite a good deal of activity reported in a small way.

Walter Fassig, president of the Ajax Block Coal Co., of Columbus, has gone to Miami, Fla., to engage in the real estate business, although he retains his connection with the coal company. He has joined with a former Columbus man who has made quite a success in Florida realty.

## OKLAHOMA

The Stigler Coal Co., Muskogee, will install a steam shovel for strip mining. W. B. Badger is secretary of the company.

Operators deny that "strike breakers" are being brought from Mexico or any other place to work in the coal mines in the Henryetta field. The denials were made after C. E. B. Cutler, attorney for the union miners, had announced that an appeal would be made to William Green, president of the American Federation of Labor, to protest to President Calles of Mexico against the sending of Mexican laborers into the coal fields. Cutler exhibited a telegram which he is said to have received from the Mexican consul at Oklahoma City, which said that it had been reported to him that Mexican laborers were being imported from Mexico to work in the coal fields.

A report from Muskogee, state headquarters of the United Mine Workers of District 21, says that M. R. Henson, secretary of the district organization, was deposed by the district executive board following an extended hearing on charges made against him recently. Henson was accused of insubordination by William Dalrymple, president of the district organization, who maintains that Henson refused to sign an expense check. The check, according to Henson, was made out to Dalrymple's stenographer and called for $6 a day for hotel expenses, which should have been only $1.50. Counter charge of misuse of the union's funds has been filed by Henson, the report says. Neither Henson nor Dalrymple would make any statement other than "it is not over yet."

While drilling for oil on a location near the town of Tonkawa, in the northern part of Oklahoma, the drilling crew struck a coal seam 13 ft. thick at a depth of slightly more than 4,000 ft., it has been reported. It is believed that the coal may be of value later, when mining at that level can be made to pay in this state.

## PENNSYLVANIA

Fred J. Dunham and William W. Brighton recently purchased from James R. Somerville Reading No. 2 mine in the C seam of bituminous coal. The mine is located on the line of the Pittsburgh & Susquehanna R.R., which connects with the New York Central at Philipsburg. The coal is considered high grade both for steam and domestic use. The firm will be known in the trade as F. J. Dunham & Co.

**Harry E. Kinloch**

Mr. Kinloch, age 71, who until Jan. 1, 1925, was general manager of the Valley Camp Coal Co., died in Parnassus, Pa., on Oct. 14, as published in *Coal Age*, Oct. 22. Mr. Kinloch started work in the peat bogs of England at the age of nine.

Pennsylvania Coal & Coke Co. and subsidiaries report a September deficit of $18,800 after ordinary taxes, depreciation and depletion, but before federal taxes, against a deficit of $50,777 in September, 1924. Deficit for the quarter ended Sept. 30 was $108,440, against a deficit of $147,547 in the third quarter of the previous year. In the first nine months of 1925 the deficit totaled $457,533, comparing with a deficit of $288,655 in same period of 1924.

The Lehigh Valley Coal Co. recently started to blow down the sides of mine caves in the Pottsville region as a precaution against someone being injured or killed while illegally digging coal during the anthracite suspension.

The Benjamin washery at Eynon, owned by Frank P. Benjamin, of Scranton, was destroyed by fire on Oct. 23. The washery was built on the site of the old Raymond breaker, which was wiped out by flames several years ago. The washery had not been operated for months preceding the fire. The owner is at a loss to explain how the blaze started.

Elmer Brunke, of Buffalo, authorized by the councilmen of that city to purchase $10,000 worth of hard coal to help relieve the shortage in that city, visited Scranton recently in quest of supply only to have his appeal turned down. The local agent for the D., L. & W. Coal Sales Co. directed the Buffalo man to take his request to the head offices in New York City.

H. C. Frick Coke Co. continues to increase its number of operating ovens. During the week orders were received to put the Whitney and Hostetter plants in full operation. These plants will work six days a week. Additional ovens were ordered fired at Marguerite and Mammoth. The Colorado Coal & Coke Co. interests have fired up more ovens in the lower "Yough" valley district. About 150 more men were put on. The plant at Clarissa recently was put to work and 70 ovens will be fired. Fifty are fired at the old Rainey plant at Fort Hill. The Washington Coal & Coke Co. has put into operation between 50 and 60 more ovens at its Star Junction plant.

Members of a mining school at Wilkes-Barre, Pa., recently saw a mechanical loader demonstrated in hard coal by its inventor, Isaac Hochreiter, of Luzerne. The front end of the loader was elevated and then the rear end, to show that it can be operated at any pitch. The inventor said the trough of a normal size loader of this type is 5 ft. wide and that it can be operated on each side of its track to clear a space 14 ft. in width. This permits the working of a face and then a return to clear up the sides of a tunnel or slope. Mr. Hochreiter said the machine may be operated by one man and that the machine and six men would load at least 30 cars a day. The loader moves forward automatically over any character of surface and cleans up as it travels, conveying débris, rock or coal to the car in the rear. A full-sized machine, the inventor said, is now being constructed for one of the operations near Scranton.

## TENNESSEE

Thirty-six hours after the arrival in Rockwood of Robert M. Lambie, chief of the West Virginia Department of Mines, the bodies of eight men who had been imprisoned in the mine of the Roane Iron Co. since July 1, were recovered. Mr. Lambie brought a picked crew of men from West Virginia, who unsealed the mine, which has been closed for months because of a raging fire and, equipped with oxygen helmets, went into the recesses of the mine, wrapped the bodies in canvas and brought them to the surface. Immediately after the bodies were brought to the surface the passages were again sealed to prevent the fire from spreading. Mr. Lambie's services were loaned on the order of Governor Howard Gore, of West Virginia, at the request of the U. S. Bureau of Mines.

## TEXAS

Texas Pacific Coal & Oil Co. reports for the quarter ended Sept. 30 net income of $584,890, after expenses and deductions, but before depreciation and depletion. This compares with $588,254 in the preceding quarter and $360,073 in the third quarter of 1924. Net income for the first nine months of 1925 was $1,666,270 before depreciation and depletion, comparing with $1,627,931 in the same period of 1924.

## UTAH

The Utah Railway Co. has petitioned the State Public Utilities Commission to approve a contract which it has made to purchase the National Coal R.R. line now in course of construction into the Gordon Creek coal properties in Carbon County, Utah's chief coal producing center. The line in question extends from a connection with the Utah Ry. about 8.9 miles up Gorley Creek and the north fork of Gorley Creek. Its completion is expected during the present year. It will serve the properties of the Great Western Coal Mines Co., the Consumers' Mutual Coal Co., the National Coal Co., the Union Coal Co. and the Sweet Coal Co.

The State Farm Bureau and the Salt Lake City Chamber of Commerce have just launched a campaign against fake stock operators. It is estimated that last year approximately $500,000 in worthless securities was sold in one county alone and that the total loss in the state would run into several millions of dollars. While no stocks are specified, it is known that promoters of mutual coal companies have been most active in the county in which it is estimated the $500,000 was lost last year. The Bankers' Association is interested in the move and a list of points to consider when stock is offered are given. It is announced that a vigilance committee will be formed in each county. Farmers appear to be among the greatest sufferers.

## WASHINGTON

The Washington Union Coal Co., Tono, is installing a new electric hoist inside the mine and an electric pump. The hoist will accommodate 12 cars a trip and the pump will have a capacity of 500 gallons a minute. The concrete foundation for this new equipment has been laid and the work will be completed this week. Alec Turnbull, master mechanic, is in charge of the operations.

## WEST VIRGINIA

Brooks S. Hutchinson, of Fairmont, vice-president of the West Virginia Coal & Coke Co., recently purchased the New Annapolis Hotel, 12th and H Sts., N. W., Washington, D. C., for $2,500,000. The hotel is 11 stories high and contains 400 rooms.

A number of operators were in Pittsburgh, Pa., last week in the interest of the West Virginia merger which fell through in New York recently. It is reported that Cleveland and Chicago banking interests probably will finance the project. It is said that $12,000,000 is involved.

Recently the State Department of Mines equipped the rescue stations at Charleston, Kilsyth, Matoaka, Welch, Williamson, Logan, Morgantown, Fairmont, Wheeling and Elkins with trucks, which are specially designed to convey the injured to hospitals or their homes, after mine fires or explosions.

Coal mines in the 12½ counties of northern West Virginia (Fairmont region) produced 572,500 net tons of coal in the week ended Oct. 24, compared to 568,200 tons the previous week, to 440,150 tons in the corresponding week of 1924 and to 523,450 tons in the corresponding week of 1923.

The Island Creek Coal Co. reports net profit for the quarter ended Sept. 30 of $618,335 after all deductions, against $478,900 in the corresponding period last year. The net profit for the September quarter equaled $4.57 a share on the 118,801 shares of $100 par value common stock, after allowing for preferred dividends. The quarter's earnings last year were $3.40 a share. For the nine months ended Sept. 30 net profit of $1,555,376, after preferred dividends, was equal to $11.20 a share, against $14.23 a share last year.

The Gilbert-Davis Coal Co. has purchased the property of the Randall Coal Co. and the Jarvis Coal Co. in Scott's Run, near Morgantown, and will be known as mine No. 6. It has been leased by R. A. and George Poland, who operated the Black mine, which will be operated on a co-operative basis, it is reported.

The Fordson Coal Co., owned by the Henry Ford interests, has contracted with the Fairmont Mining Machinery Co. for a $55,000 steel headhouse and a 1,300 ft. rope and button conveyor at its Nuttallburg mine, in Fayette County. The contract calls for installation by March 1.

Harry A. Cochran, of Baltimore, coal traffic manager of the Baltimore & Ohio R.R., who was a business visitor to Fairmont last week, reports that during September the B. & O. moved 3,250,000 net tons of coal on its system, exclusive of company fuel, obtained for its own consumption. It was one of the biggest months in the history of the B. & O.

J. W. Bischoff, of Elkins, formerly general superintendent of the West Virginia Coal & Coke Co., was recently made superintendent of the Parker Run mine of the Fairmont & Cleveland Coal Co., the largest single tipple mine in northern West Virginia. He succeeds Charles E. Gaskill.

## WYOMING

W. L. Kidneigh, for several years past connected with Rock Springs offices of the Megeath Coal Co., of Omaha, has resigned and will go to California, where he is a partner in the Aladdin Sales Co., of San Francisco. He is succeeded by H. W. Moran, of the Omaha offices of the Megeath company.

Mines in the Rock Springs district would be working full time at present if sufficient coal cars were available. Many of the mines of the Union Pacific Coal Co. lost a day during the week ending Oct. 10 because of a car shortage. The increased freight business of the U. P. R.R. is creating a greater demand for the coal of this district. One day recently this road handled 95 freight trains through Rock Springs.

The Megeath Coal Co., whose headquarters are at Omaha, has increased the output at its Rock Springs mine within the last six months to 700 tons daily, an increase of almost 100 per cent. Since William Redshaw, for several years superintendent of the U. P. mines at Winton, was made superintendent in the spring of 1925, much improvement and safety work has been accomplished.

## CANADA

Officials of the Dominion Coal Co. state that the outlook for the Nova Scotia coal industry is fairly good for the next four months. An order is expected from the United States for 50,000 tons per month and if it materializes the Cape Breton collieries of the British Empire Steel Corporation will be kept busy until the end of February. The number of miners who have recently left the United Mine Workers is about 300 in addition to 700 who broke away from the union in Pictou County.

Production of coke in Canada during September totaled 102,882 tons, as compared with 95,397 tons in August, an increase of 7 per cent. The gain was largely due to the increased production in Nova Scotia since the settlement of the strike. Ontario ovens produced 53,533 tons or 52 per cent of the total Canadian output. The amount of imported bituminous coal used for coke making was 109,015 tons, as compared with 115,683 tons in August, and the amount of Canadian coal used rose from 26,379 in August to 48,468 tons in September. Imports of coke totaled 78,731 tons as compared with 70,000 tons in August. Exports were 4,268 tons as against 2,007 tons.

The Canmore Coal Co., of Alberta, is erecting a new briquetting plant, which when completed will cost in the neighborhood of $100,000. The building is being erected by the coal company, the machinery being supplied under contract by Komarek-Greaves Co., Chicago. The plant will be ready for operation about the middle of November.

Coal output in British Columbia during the first nine months of this year was 327,717 tons greater than for the corresponding period of 1924, according to a statement by the provincial Department of Mines. Output by districts during the first nine months of 1925 was: Crows Nest Pass, 653,752 tons; Nicola-Princeton, 116,898 tons; Vancouver Island, 1,006,368 tons, a total of 1,777,018 tons. The gain is due to increased production in the Crows Nest Pass field, which for more than six months of 1924 was closed by a strike.

# Traffic

### New Coke Rates on B. R. & P. Are Approved

The New York Public Service Commission has approved new rates on the Buffalo, Rochester & Pittsburgh R.R. on coke and coke breeze, to main line stations Buffalo to Barnard inclusive, $1.39 per net ton; Buffalo to Chace, Perry and Silver Lake, $1.89; effective Oct. 17. The commission also has approved the establishment of joint rates by the Lehigh Valley, Geneva to B. R. & P. stations, Garbutt, Maplewood, Mumford, Rochester and Scottsville, $1.51; effective Oct. 21.

## Coming Meetings

**Illinois Mining Institute.** Fall meeting, Nov. 6 and 7 at West Frankfort, Ill. Secretary, Frank F. Tirre, St. Louis, Mo.

**Harlan County Coal Operators' Association.** Annual meeting, Nov. 18, at Harlan, Ky. Secretary, E. R. Clayton, Harlan, Ky.

**American Society of Mechanical Engineers.** Annual meeting at New York City, Nov. 30-Dec. 3. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**Fourth National Exposition of Power and Mechanical Engineering.** Nov. 30 to Dec. 5, at Grand Central Palace, New York City.

**Coal Mining Institute of America.** Annual meeting, Dec. 9-11, Pittsburgh, Pa. Secretary, H. D. Mason, Jr., P. O. Box 604, Ebensburg, Pa.

**American Mining Congress.** Twenty-eighth annual convention, Dec. 9-11, Washington, D. C. Secretary, J. F. Callbreath, Munsey Bldg., Washington, D. C.

## New Companies

**The Uniflow Stoker Co.**, Piqua, Ohio, has been chartered with an authorized capital of $15,000 to manufacture and deal in mechanical stokers. Incorporators are: Walter E. Turner, Fred A. Shane, Walter F. Henne, August Clouse and Leslie T. Hunnicutt.

**The Magnolia Coal Mining Co.** of Russellville, Ark., with a capital of $25,000, has been incorporated by J. L. Davis, T. A. Johnston, E. G. Butler, Essie Lee Davis, T. G. Johnston and J. H. A. Baker.

**The Moniteau Coal Co.**, Higbee, Mo., has been incorporated with a capital of $40,000 and will carry on a general mining business. The incorporators are James Rankin, Joe Bradley, Mike Marietta, Fred R. Laight and Chas. B. Moore.

**The L. H. & W. Coal Co.**, Henderson, Ky., with a capital of $28,000, has been incorporated by U. M. Gager and Harry B. Jennings.

## Recent Patents

**Method for Separating Materials of Different Specific Gravities;** 1,545,636. Thomas M. Chance, Philadelphia, Pa. July 14, 1925. Filed Oct. 14, 1921; serial No. 507,605.

**Automatic Trapdoor for Mines;** 1,645,-274. Ren Williams, West Frankfort, Ill. July 14, 1925. Filed Sept. 27, 1924; serial No. 740,297.

**Storage Plant for Coal;** 1,547,290. Robert H. Beaumont, Radnor, Pa., assignor to R. H. Beaumont Co., Philadelphia, Pa. July 28, 1925. Filed Nov. 15, 1923; serial No. 674,841.

**Apparatus for Crushing Coal;** 1,547,491. Emil Barthelmess, Dusseldorf-Oberkassel, Germany. July 28, 1925. Filed Sept. 13, 1924; serial No. 737,572.

## Obituary

**Walter D. Hunt,** 36 years old, a member of the firm of Hunt Brothers, coal operators at Brazil, Ind., died recently at his home following an illness of two weeks of influenza. He had been a resident of Brazil for a number of years and had been engaged in the coal business for the last ten years. He is survived by a widow, a son and a daughter.

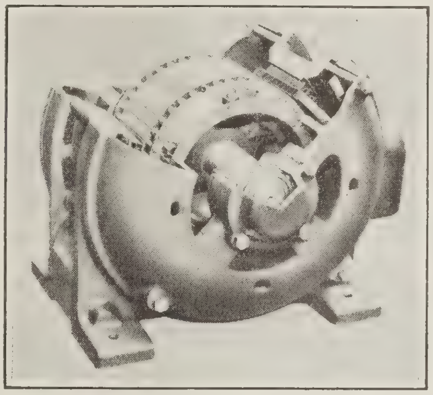
The death is announced of **Edward A. McConn**, at the home of his niece, Mrs. G. J. Coy, of Baltimore. Mr. McConn was formerly associated with the H. C. Frick Coke Co. of Scottdale, Pa. He was 81 years old and for the past forty years had been a resident of Scottdale.

**Milton Mayo**, brother of the late John C. C. Mayo, of Paintsville, Ky., the man responsible for the big Elkhorn operations of the Consolidation Coal Co., was found drowned in 6 in. of water, in a small stream near his home on Oct. 12. The deceased was partly paralyzed, and indications are that he fell into the stream, and was unable to help himself. Milton Mayo was not wealthy, the bulk of the vast fortune of his brother, John Mayo, having been left to his widow and children. A brother, Robert Mayo, and a sister, Mrs. Fred Atkinson, of Paintsville, survive.

# New Equipment

## Heavy Roller Bearings Adapt Motor to Severe Duty

After two years of experimentation and development the Allis-Chalmers Manufacturing Co., of Milwaukee, Wis., has placed on the market a line of roller bearing induction motors of the type shown in the accompanying illustration. These are of both the squirrel cage and slip ring varieties and are built for both 25- and 60-cycle current. They are, of course, in addition to the sleeve bearing motors which this firm has marketed for years.



**Sectionalized View of Motor**

Tapered roller bearings upon either end of the armature shaft take both radial and end thrusts readily. Grease packing in these journals renders attention unnecessary except at long intervals.

In the construction of these motors the Timken taper roller bearing has been selected because this type is capable of enduring heavy and continuous radial and end thrusts. It is, therefore, particularly adapted to withstand heavy service at high speeds. Because of its rolling action this bearing has practically no wear and the factory-adjusted air gap is maintained indefinitely, with little or no possibility of the rotor dragging on the stator.

Grease is employed as a lubricant and the bearing inclosures are made grease tight, effectively excluding grit and dirt that might cause undue wear. With these provisions both motor and bearings require only infrequent attention, and both are well adapted to installation in dusty or dirty places. A light press fit for the cone and cup of the bearing is sufficient to hold these parts in place, no nuts or other locking devices being required. Bearings may be removed easily when necessary.

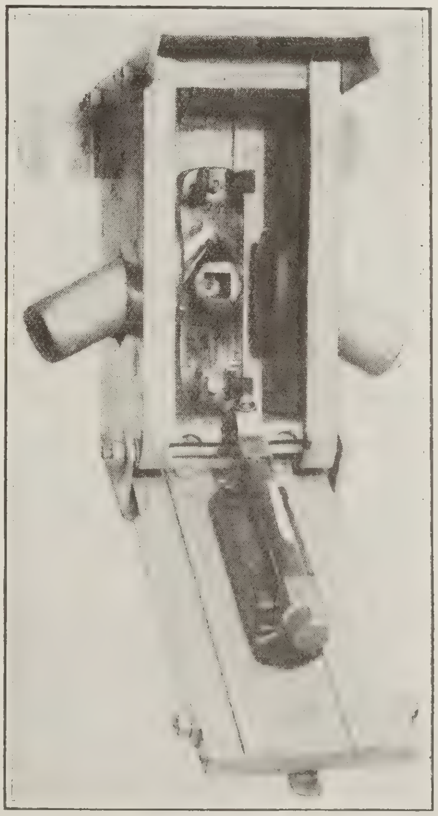
In addition to the bearings, other details of design have been carefully considered. Thus the frame has been made of steel casting with integral feet. The coils of the various windings are thoroughly insulated and baked in a waterproof varnish. Ventilation openings in the housing and frame are so placed in vertical planes that falling objects cannot enter the machine. The overall length of this motor is appreciably less than that of sleeve bearing machines of like capacity admirably adapting it to close-quarter installations.

It will be readily apparent that this motor is of rugged design intended to meet successfully and withstand conditions of operation that are unusually severe. It is now being built in all sizes up to 200 hp. for various voltages of both 25- and 60-cycle current.

## Fuse Box Prevents Contact With Live Parts

Recent improvements in the design of fuse boxes for distribution transformers, so that it becomes impossible for the operator when re-fusing the box to come in contact with current-carrying parts have been made by the Westinghouse, Electric & Manufacturing Co.

The new OD safety-first fuse box is of this type. It consists of a heavy, compact, moisture-proof box, fitted with special mounting brackets that permit it to be installed at the maximum distance below the transmission wires. The door of the box is hinged at the bottom and is interlocked so that it can be removed or replaced only when the fuse tube is at a safe distance



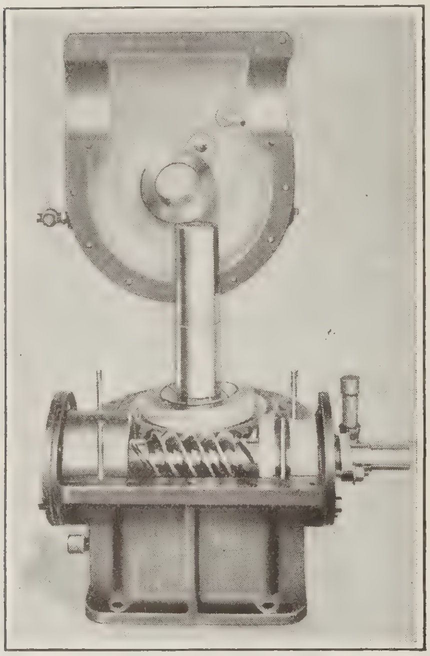
**Fuse Is Automatically Taken Off Line**

The work of renewing the fuse element in this box is made safe by taking the fuse out of the circuit when the door is opened.

from the line contact. A screwdriver to clamp the fuse link in the new tube is the only tool needed when re-fusing. To insert a new fuse the operator opens the door of the box which action disconnects the fuse and insulates it from the line. He then lifts off the door, inserts the refill in the tube, replaces and closes the door, and the box is again ready for operation.

## Oil Forced to Upper Bearing In Vertical Gear

Occasionally in and about the mines application is found for vertical worm reduction gears. Such a device has recently been brought out by the DeLaval Steam Turbine Co., of Trenton, N. J. This gear, shown in the accompanying illustration, has the advantage that where the driving shaft is horizontal, as is usually the case, the motor may be stowed away beside the machine instead of projecting out into aisle space.



**Reduction Gear with Cover Removed**

In this machine a cam on the worm gear actuates a pump that supplies oil to the upper main bearing. In the large high-speed units where immersion of the gears is disadvantageous this pump also lubricates the worm and gear surfaces.

This reducer is unique in that the upper bearing is supplied with oil by forced or positive lubrication, the pump feeding this oil being mounted within the casing and operated by a cam. Suitable filling and drainage openings, together with trycocks provide adequate means for the control of the oil level. About all the attention that this type of reduction gear requires is a periodic inspection of the oil level.

In the larger sizes of these reducers, where the speeds of operation are high, it is disadvantageous to immerse the gears in oil on account of the fluid friction. In such cases an oil pump lubricates not only the upper bearing but the worm and gear as well. This reduction is made in a variety of sizes and with shafts extending either up or down.

## Publications Received

**Mechanical Loading in Coal Mines**, by F. E. Cash and E. H. Johnson. Coal mining investigations under the auspices of the Carnegie Institute of Technology, U. S. Bureau of Mines and Advisory Board of Coal-Mine Operators and Engineers. Bulletin 17. Price $1. Pp. 113, 6 x 9 in.; illustrated. A discussion of the prime factors in the success of loading machines, including transportation and mining methods, descriptions of types of machines and actual operations, costs, advantages of mechanical loading and suggestions as to choice of a loader.

**Annual Report of Coal Mine Inspection and Mine Rescue Departments**, by Leon Besson, State Mine Inspector, Pittsburgh, Kan. Pp. 139; 6 x 9 in.; tables.

**Quantity of Wood Treated and Preservatives Used in the United States in 1924**, by R. K. Helphenstine, Jr., Forest Service, U. S. Department of Agriculture, in co-operation with the American Wood Preservers' Association. Pp. 36; 6 x 9 in.; tables and charts.

**The Coal Resources of Canada**, by M. J. Patton. Bulletin No. 50 of the Departments of History and Political and Economic Science in Queen's University, Kingston, Ont., Can. Pp. 19; 6 x 9 in.; tables.

**Geological Maps**, Their Study and Use, by A. Nelson. Colliery Guardian Co., Ltd., 30 Furnival Street, Holborn, London, E.C. 4, Eng. Pp. 108; 6 x 9 in.; illustrated. A handbook for mining students, geologists and surveyors.

**The Smoky River Coal Field**, by James McEvoy. Published by the Dominion Fuel Board in co-operation with the geological survey and Department of Mines, Ottawa, Can. Pp. 19; 6 x 9 in.; illustrated. Examination and comparison with the Kananaskis area.

**Annual Report of the Mines Branch of the Province of Alberta, Canada for 1924.** Pp. 372; 6x10 in.; tables.

**Screen Sizing of Coal, Ores and Other Minerals**, by E. A. Holbrook and Thomas Fraser. Bureau of Mines, Washington, D. C. Bulletin 234. Pp. 140; 6x9 in.; illustrated. Prepared under a co-operative agreement between the Bureau of Mines, State Geological Survey Division of Illinois and the Engineering Experiment Station of the University of Illinois. Outlines present practice in screening coal and supplements that information with basic points which must be considered by both designing and operating engineers.

**Mineral Resources of the United States in 1924.** (Summary Report). Introduction by Frank J. Katz; statistics assembled by Martha B. Clark, from data furnished by specialists of the Division of Mineral Resources, U. S. Geological Survey, Washington, D. C. Pp. 108; 6x9 in.; tables. The arrangement of this seventh annual preliminary summary of the country's mineral production is alphabetic by minerals and conforms to earlier issues.

**Sources of Limestone, Gypsum and Anhydrite for Dusting Coal Mines to Prevent Explosions**, by Oliver Bowles. Bureau of Mines, Washington, D. C. Bulletin 247. Pp. 70; 6x9 in.; illustrated. Covers causes, propagation and prevention of dust explosions, cost of dusting coal mines and availability of dusting materials.

**The Physiography of the Upper James River Basin in Virginia**, by Frank J. Wright. Virginia Geological Survey, University of Virginia, Charlottesville, Va. Bulletin XI. Pp. 67; 7x10 in.; illustrated. Covers results of a detailed study of the surface features of the central part of the Valley province of Virginia.

**Rewinding Small Motors**, by D. H. Braymer and A. C. Roe. McGraw-Hill Book Co., 370 Seventh Ave., New York City. Price $2.50. Pp. 247; 6x9 in., illustrated. Describes practical details of repair-shop practice with step-by-step procedure for rewinding all types and designs of fractional horsepower motors.

**The Coal Deposits and Coal Mining of Svalbard** (Spitzbergen and Bear Island), by Adolf Hoel. The Norwegian Academy of Arts and Sciences, Oslo, Norway. Vol. 1, No. 6. Pp. 92; 6 x 10½ in.; illustrated.

**Soil Survey of Tucker County, West Virginia**, by S. W. Phillips. U. S. Department of Agriculture, Bureau of Soils, in co-operation with the West Virginia Geological Survey. Pp. 36; 6 x 9 in.; illustrated.

## Association Activities

**The Cincinnati Coal Exchange** at a meeting on Oct. 20, shied at the idea of accepting associate members into that body. The Exchange is a subsidiary of the Chamber of Commerce and it was proposed that firms holding this membership might have other members of their company in as associate members. R. A. Colter and R. P. Gillham, old members of the trade, balked. The matter was referred back to a committee consisting of Ernie Howe, Fred Legg and George Kearns.

## Industrial Notes

Arrangements have been recently effected whereby the **Chicago Pneumatic Tool Co.** of New York has obtanied the right to manufacture and sell the Benz Diesel engine in the United States and Canada. This machine is of the solid injection, vertical multiple cylinder, four stroke cycle type. Like other Diesel engines it has no ignition device thus eliminating a rather delicate mechanism. It is provided with automatic regulation and the entire machine is simple both in construction and operation.

Any kind of petroleum or any of its derivatives can be utilized in this engine. Speed regulation is effected by means of a precision governor which controls the valve on the injection pump, the fuel admitted to the cylinder being thus in exact proportion to the load on the machine. Because of its simplicity and economy this engine should find application at many mines especially as a standby unit to be employed in case of failure of the regular power supply.

**Brown, Boveri & Co., Ltd.**, builders of electrical equipment at Baden, Switzerland, is about to establish an associate manufacturing company in the United States similar to those already created in Great Britain, Belgium, Holland, Norway, Finland, France, Germany, Austria, Denmark, Hungary, Italy, Sweden, Spain, Poland and Czechoslovakia. The company had part in the harnessing of the power of Niagara, electrified and aided in the construction of the Simplon Tunnel and built the first long-distance power-distribution system which runs between Lauffen and Frankfort and is said to be the first to be constructed anywhere in the world.

**The Uehling Instrument Co.**, of Paterson, N. J., recently appointed the Ernest E. Lee Co., 115 South Dearborn St., Chicago, as its representative in northern Illinois and northern Indiana in connection with the sale of $CO_2$ recorders, fuel waste meters and other power-plant instruments. The Coon De Visser Co., which has been representing the Uehling Instrument Co. for several years in Michigan, has just moved from 1772 West Lafayette Blvd. to 2051 West Lafayette Blvd., Detroit.

Edward D. Kilburn, vice-president and general manager of the Westinghouse Electric International Co., and Walter S. Rugg, general sales manager of the **Westinghouse Electric & Manufacturing Co.**, were named vice-presidents of the latter company at a recent meeting of the Board of Directors in New York. At the same time Richard B. Mellon, of Pittsburgh, President of the Mellon National Bank of that city and a brother of A. W. Mellon, Secretary of the U. S. Treasury, was elected a director of the company. Mr. Mellon will fill the vacancy caused by the death of William McConway, formerly president of the McConway & Torley Co. Messrs. Rugg and Kilburn will take charge, respectively, of the engineering and sales activities, according to announcement by Vice-President F. A. Merrick, general manager of the company. Vice-President H. D. Shute, aside from the direct operation of the sales department, which will be handled by Mr. Kilburn, will retain his direction of the broad commercial activities of the company, including especially customer relationships. Vice-President H. P. Davis, formerly in charge of engineering and manufacturing activities as applying to the strictly electrical portions of the company's business, will have direction over the entire manufacturing activities of the company and, in addition, will have direction of the general features of the radio business including broadcastings. Mr. Kilburn, in addition to his new appointment, will retain his duties as vice-president and general manager of the Westinghouse Electric International Co.

## By Way of Comparison

ALL OUR JUDGMENTS are comparative and until we have measured each fact with some other like it as a standard we can hardly discover its real value. It is, therefore, illuminating to state that the Census of Manufacturers for 1921 shows that in Pennsylvania the wage earners in the anthracite industry received in the aggregate 28 per cent as much as the employees in manufacturing industries and yet there were only about 18 per cent as many anthracite employees as employees in manufacturing industries.

The average annual wage in all Pennsylvania manufacturing industries was $1,165 and at the anthracite mines, $1,780—a figure obtained by dividing the average number of men employed at the mines in 1921, as reported by the U. S. Geological Survey, into the total anthracite mines' payroll for the year as reported by the state Department of Internal Affairs. Since then wages in all manufacturing industries have declined, but the wages of anthracite mine workers have increased 10 per cent, so that with equally steady work the wage of the mine worker should be $1,958 per year. Overlooking the decrease in the wages of manufacturing employees, the present wage of the mine workers in the anthracite region can be calculated as exceeding that of manufacturing employees by 68 per cent. Compare these wages with those paid in 1923 in certain skilled industries of Pennsylvania:

| | |
|---|---|
| Newspapers and periodicals | $1,722 |
| Blast furnaces | 1,694 |
| Steel works and rolling mills | 1,623 |
| Railroad repair shops | 1,602 |
| Electrical apparatus and supplies | 1,337 |

To put the figures in less statistical form, the anthracite miner has been asking the average industrial worker to work five days for him in return for three days of his labor. The mine worker will not trade on an equal basis day for day with even such skilled men as newspapers employ, but wants 14 per cent more time. To supply and intensify this anomaly a strike is now instituted by the overpaid mine worker to get a 30-per cent increase.

## Ebb and Flow in Britain

IN THE UNITED STATES many mines have been closing and others opening during the past year. Unionism and non-unionism have something to do with this, but some of the mines which have closed have been mines of the high-cost type—old and ill developed—and others that have been opened have seemed good projects as they were new and could be well equipped.

In Great Britain a like tendency is quite manifest. A paper reports the fact that in the Rhymmny Valley of South Wales 10,000 men are idle, that Mardy Colliery is to be closed, that the Bargoed Colliery has been shut down for a month, that fourteen-day notices have been served on 4,000 miners at the Beynon pit, Blaina, the Prince of Wales, Abercarn, Cwmcarn, and at Nos. 2 and 4 mines, of D. Davis & Sons. The same paper records also the sinking of three new shafts in the Yorkshire fields, one at Thorne, another at Ollerton, and the third the Markham Colliery of the Stavely company. Depth does not hinder development. The coal in the Thorne mine will be nearly 2,800 ft. deep. What is necessary is a new operation not hampered by prior mistakes and ancient practices.

The closing of old mines and the opening of new would be even more rapid if the British were to open their hearts to the radical changes in equipment that decrease costs and make high wages possible. Perhaps if they did that they might forestall many radical political changes, unless, indeed, the revolutionary development had the contrary effect of creating a ferment of mind, where mines, grown out of date, had to be closed.

## The World's Darkest Job

NO INDUSTRY OPERATES as much in the dark as coal mining. Less light is provided and what illumination there is quite largely is lost in the light-absorbing walls of the mine. Thus coal mining is pursued in even deeper darkness than metal mining. It is a wonder that efforts have not been made to illuminate mines adequately by stationary lights along the headings and at the face. Speedy, energetic work can only be obtained where men can see what they are doing, and the right psychological attitude toward work is attained only when men have light to cheer them.

Fewer accidents will occur when more light is provided. Men stumble around in semi-darkness unable to see their work clearly. Where the reflector of the lamp is directed, an area is illumined, but all around is Stygian darkness. A few stationary lights properly placed would make conditions better but even then the mine would still be as badly illuminated as the average factory was one hundred years ago or more. There is safety in sight, there is speed also, certainty and comfort. Better light is coming. Men are not going to poke around in the dark forever with science so prodigal with new illuminating devices. The portable lamp is needed, and doubtless always will be needed, to throw the light in the immediate spot where the actual work is being done, but there is no reason why all the rest of the workings should be enshrouded in impenetrable darkness.

## Timbers as Rock-Dust Shelves

WHERE TIMBERS have been cleaned of coal dust and well covered on their upper surfaces with rock dust they furnish an excellent preventive against coal-dust explosions. A long row of timbers should be a continuous rock-dust barrier, ready at all times to put a curtain in the path of the advancing storm. A few boards might be run from timber to timber and loaded with rock dust as further precaution if any were needed. These could be of such length and so located that they would be easily displaced by a blast.

## Those Hot Bearings

WHAT INSURANCE MEN dread in coal breakers is that some of the bearings may heat and cause a fire. Every pedestal or block is a possible source of a conflagration. Prudence would dictate that as few bearings as possible be used, that bearings be provided that are not likely to heat and that speed reducers that run in oil and are inclosed be used instead of open gear trains. Where pump machinery is installed underground the same is true. A fire starting below ground at an unattended pump may do damage as great as a fire in a big breaker.

## Building for the Future

THE HOPE of Central Europe burns dimly because of the spirit of hatred existing between the many peoples. Oppression and wrong have done their fatal work. There is no willingness in any one to believe good of another, and the man of kindly, charitable attributes is suspected just as others are. It has taken a long time to create this ferment of mutual distrust, but Central Europe will be still longer overcoming it.

This object lesson needs to be considered in our country by employer and employee alike. Mutual faith cements peoples and makes for success. The United States has prospered on such an understanding. This mutual respect has been the basis of large production. Co-operation has been the keystone of our progress. A corporation or a union that overlooks the importance of friendliness in the conduct of its business will some day face a grievous condition. The blame may by each be transferred to the other, but what satisfaction is it to blame the other party if we can not allocate the misfortune as well as the blame.

Where parties are mutually exasperating, contact only increases the ill feeling. Where, however, the relationship is pleasant, continued contact makes the association of the parties the more binding. The company or the union that is always bound to get its rights to the last nickel and even strives at times to get much more will find in the end that what it strove for is a lesser conquest than that which a less contentious spirit would have achieved without effort.

## New Uses for Slack

SO LONG AS in the obtaining of screen coal enough slack is produced to flood the market, the smaller sizes will sell at a bargain. In the summer time the lack of market for domestic bituminous coal does at times even cause a shortage of small sizes, for some mines will not run at all if they cannot sell domestic coal or cannot obtain for run of mine prices that are all too high for those to pay who need only slack.

The cure for the situation is to increase the sale for fine sizes to such proportions that there will be a perennial shortage such as can be cured only by buying run of mine, crushing the coal at the steam plant and paying enough for such sizes to justify the production of coal for the steam market alone. That condition might have been here quite generally already had not notable economies in the use of steam coal been made, but any advance such as using coal for cooling purposes or for extensive sprinkling and irrigation of farms would make the demand for coal so great that the price paid for slack would have to be raised.

The supply will then be forthcoming only when such a price is paid for it as will make it profitable to run mines with the sole purpose of producing steam coal. Mines in some sections already do this, but it should be the case everywhere. It should be possible to run any mine as profitably producing run of mine as producing a screened product. Of course, the man who prepares his coal carefully will get a better price for it or he will produce run of mine only, but the real profits, after interest on the greater investment and after consideration of the greater cost of handling, billing and balancing a screened product are allowed, should be almost equal.

The research committee of the National Coal Association, therefore, is well justified in looking for additional uses for steam coal even though for the summer months only, when fine sizes are relatively scarce. The power companies probably will buy in the winter to stock for summer use unless the demand is so great that mines may have to be run on run of mine to supply the product in all seasons.

On the whole uncleaned slack if sold on its merits for stoker use and not on the basis of supply and demand should sell at a better price than uncleaned run of mine because it does not have to be crushed and is, probably, less likely to fire in storage. So much run of mine today, however, is screened, the lumps hand-picked and the whole reassembled that run of mine is cleaner than screenings and rightly commands a better price.

## Food from Coal

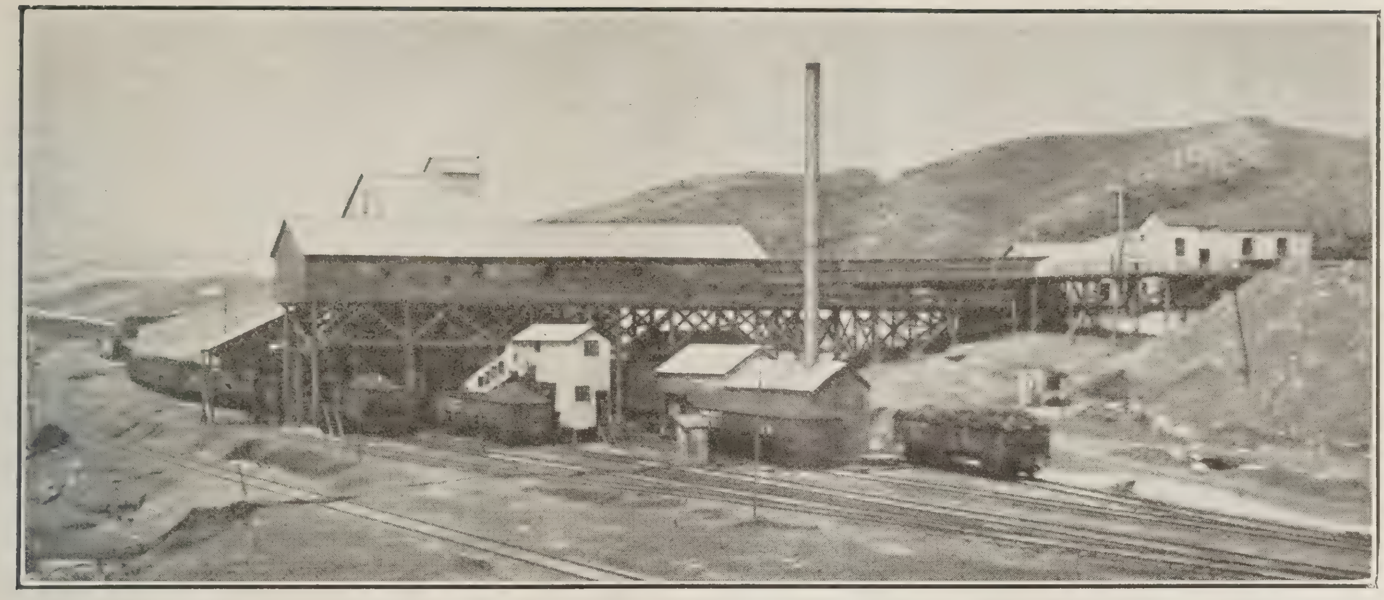
MODERN CIVILIZATION is demanding more and more nitrogen—that element which makes up nearly 80 per cent of our atmosphere but which cannot be utilized until it has been forced into chemical combination with some other element such as hydrogen. Ammonia, a combination of this kind, yields readily to chemical processes for conversion into fertilizer and other products so necessary in the arts of peace and war.

We have heard so much in the last few years of the association of water power and cheap fertilizer that it is a relief to learn of the plant which is being completed near Charleston, W. Va., for the production of 25 tons per day of ammonia from bituminous coal. That this plant is one of the Dupont industries makes it the more impressive as a forerunner of a new and extensive use for coal. Ammonia from coal; fertilizer from ammonia; and food from almost any soil when fertilized! What have the coming generations to worry about?

THIS IS HOW the miners' union lives up to its claim that it aids the development of new mining machinery: An Indiana operator started to test out a cutting-shooting-loading machine. Its operation required the firing of half-pound shots of permissible powder with men in the mine. The state law permits shots at least twice that size while men are underground. A union order to its members, however, required them to get out of the mine every time a charge was fired. Of course the machine got out instead. Who knows but that it might revolutionize mining—if it got a chance?

WITH COAL AND FORDS both shipped from the same Duluth dock, Northwest consumers may kick about tramp iron in their fuel only if there are no spotlights, self-starters and demountable rims on it.

IF LEWIS CALLS a soft-coal strike with no more cause than he now has, the public ought to call it a foul strike.



# Shaking Conveyor Eases Labor in Pitching Coal

## At Sublet, Wyo., a 3-Deg. Chute Along 100-Ft. Face Discharges to Another Inclined at 20 Deg. Which Delivers Into Cars with Little Breakage en Route

**By R. Dawson Hall**
Engineering Editor of *Coal Age*
New York City

When a bed of coal pitches at 20 deg. or thereabout it offers a difficult mining problem. It is so steep that it is hard to work by rooms driven on the strike. The steepness also makes it difficult and dangerous to work with cars on the pitch, because any contrivance, such as a McGinty, which causes the loaded cars to pull up the empties, is likely to dislodge the posts that hold it and cause frequent and dangerous runaways. Ropes break and brakes fail to hold. Consequently, any such method is rarely favored even with slopes far less steep.

On a sheet-iron chute inclined at 20 deg., some kinds of coal such as that mined at Sublet, Wyo., will not run without bucking, though that at Elkol in the same state will run freely on a somewhat lighter grade. Apparently the shape of the lumps is important. A coal that breaks into a slab-like form will slide less freely than one that is more or less cubical and still less freely than one that is rounded. With a slab-like coal on a 20-deg. grade a number of men have to aid the movement of the coal and it may well happen that more have to be employed to buck the coal than to mine it, for it is always uncertain just where the material will choke and need dislodging.

For this reason at Mine No. 5, Sublet, Wyo., a plant of the Kemmerer Coal Co., about nine miles north of Kemmerer, shaking chutes have been provided. It is remarkable how readily coal will move down a slight incline, on the level, or even on a slope inclined a few degrees uphill when resting on a chute having a differential motion. When the chute goes forward slowly, the coal moves with it but when the chute is jerked suddenly backward the coal fails to follow and retains the progress it has made on the forward stroke, thus awaiting the time when another forward movement of the chute will give it a further travel in the same direction.

In Sublet, the face chute is placed on a 3-deg. inclination, but it would work acceptably uphill. The coal does not roll or bounce forward even on the full pitch. It merely slumps or shuffles along at a speed dependent on the grade and the violence of the reciprocation. There is, in consequence, little dust, little degradation and remarkably little sound, far less of the last and probably less of the second than with an apron conveyor. I am not sure but what the same claim can be made for the first of these advantages, for the motion is so easy that dust should not be raised. The coal has a relatively silent passage, giving the shovelers an opportunity to hear the cracking of the face, roof or props should pressure manifest itself and give warning.

The shaking-chute working in Sublet lies between the Eleventh and Twelfth South Entries. Operations at that point can hardly be termed longwall mining for the face is only 100 ft. in length. The coal over that width of operation is entirely removed on the advance. The work is carried straight up the pitch but the face is not exactly at right angles to the direction of progress, but is inclined so as to lie at an angle which gives the face line and conveyor serving it an inclination equal to 3 deg. from left to right.

The face conveyor is placed about 5 ft. from the coal face and about five rows of props at 5 ft. centers (each prop in any row being 5 ft. from its fellow) are placed or retained back of the conveyor. However, as the face advances, other props are set, so that before the con-

---

The headpiece is a general view of the No. 5 tipple at Sublet. It is in the mine under the hill at the right that shaking conveyors are being tried and among other things are doing much to increase the size of the product marketed even though the coal is shot off the solid.

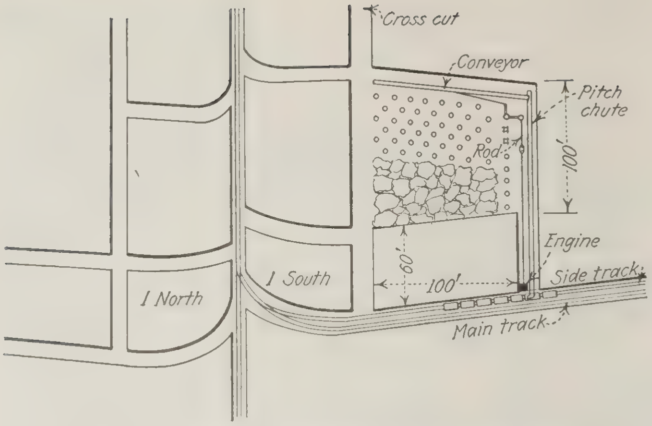


**Fig. 1—Plan of Conveyor in the Workings**

This shows the layout of the conveyors and mine passages. The face and heading chutes meet at an angle that is a little less than 90 deg. The slope of the face conveyor is small but the heading conveyor is laid on the full pitch of the coal bed.

veyor is moved forward, two rows of props lie between it and the face, without, however, interfering with the shoveling of coal.

At its right, or lower end the face conveyor discharges to a second conveyor that transports the coal to the entry. Delivery from one chute to the other is at almost a right angle, yet is accomplished without spillage. The coal travels rapidly down the second or pitch conveyor and at its end enters a curved section that makes delivery to the mine car below in a direction parallel to the track.

Each section of the heading chute is suspended by a pair of chains or heavy wires from a light crossbar or pipe extending between posts set up on either side of the conveyor. The face chute is similarly supported except that its upper end is carried by a pair of rollers running on a light structural frame about 2 ft. long laid directly on the floor. The forward stroke of both conveyors is imparted by the motor-driven engine and the return stroke by a heavy helical spring. The engine is linked to the heading chute by means of a simple connecting rod and to the face chute by a rope terminating in a turnbuckle adjustment, pinned to one arm of a bell crank, the other arm of which is connected by a rod to the conveyor chute. Amplitude of the face conveyor's oscillation is adjusted by changing the position of the connections to the two arms of the bell crank.

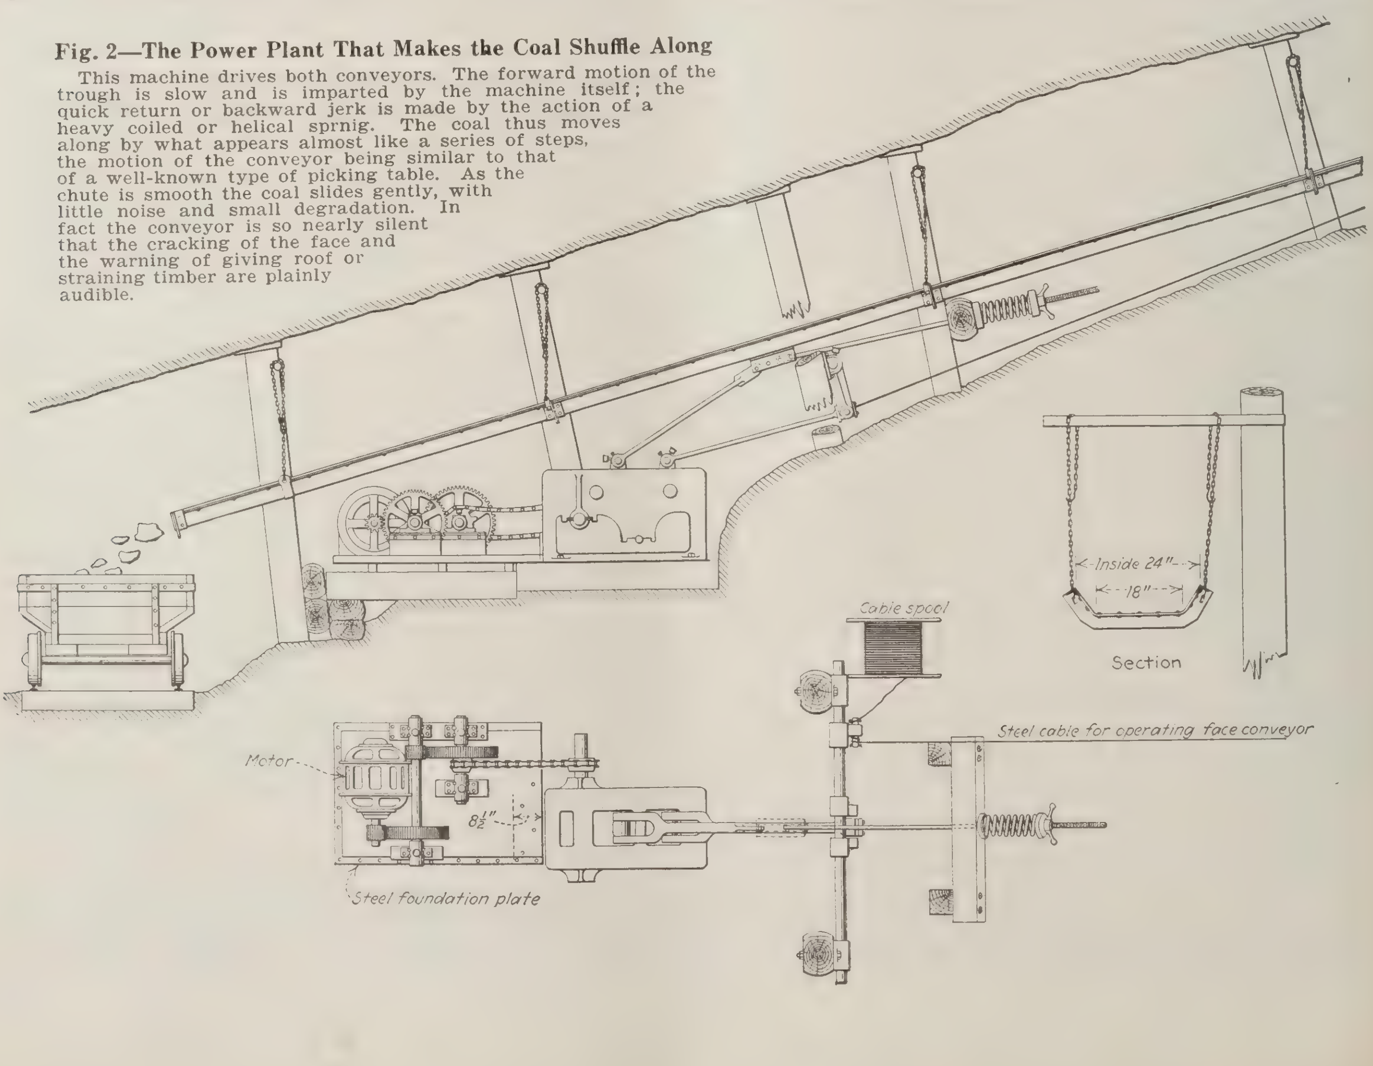
By the introduction of these shaking-chute methods, the work of mining is greatly concentrated making less development necessary, decreasing the area to be ventilated, superintended by foremen, inspected by firebosses, sprinkled with water or treated with dust. The pressure of the roof helps to break down the coal making it unnecessary to use more than about a quarter the quantity of powder that otherwise would be required. Undercutting is not necessary, nor is it practiced.

It is likely that in the future a greater length of working face will be provided, still further decreasing the costs for standing development, for ventilation, superintendence, inspection, sprinkling, rock dusting and shooting. The use of longwall makes possible a more nearly complete recovery, for without such a system and using room methods none of the pillars could be withdrawn.

The coal which is clean and about 5 ft. 6 in. thick has well defined and frequent cleats that make it easily mined whenever the advance is in a direction that takes

**Fig. 2—The Power Plant That Makes the Coal Shuffle Along**

This machine drives both conveyors. The forward motion of the trough is slow and is imparted by the machine itself; the quick return or backward jerk is made by the action of a heavy coiled or helical sprnig. The coal thus moves along by what appears almost like a series of steps, the motion of the conveyor being similar to that of a well-known type of picking table. As the chute is smooth the coal slides gently, with little noise and small degradation. In fact the conveyor is so nearly silent that the cracking of the face and the warning of giving roof or straining timber are plainly audible.



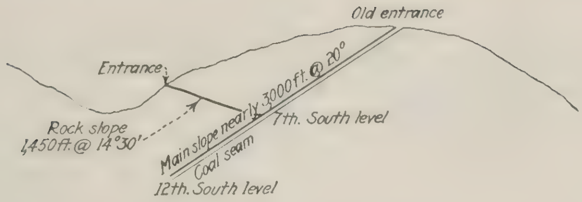


**Fig. 3—Sketch of Surface Contour**

When this mine was first opened the main slope followed the pitch of the coal bed. More recently a rock slope has been driven from tipple height in the valley to intercept the coal bed at about the Seventh Level.

advantage of those qualities. The roof for about 200 ft. above the coal is weak and falls readily when not supported, breaking into small fragments. Above that a 54-ft. seam of sandstone is found which probably interposes a greater resistance. Of all the overlying strata this measure alone shows marked strength. The cover above the coal is from 1,000 to 1,100 ft. in depth at the Twelfth South Level.

### Make New Rock Slope

Those who are disposed to take a pen and a table of sines to ascertain the depth should be informed that the former entrance to the mine and the outcrop of the seam are near the top of the hill on one side of the canyon. A new rock slope has been made from tipple height in the valley. This pitches at an angle of 14½ deg. and strikes the former slope on the hanging wall at about the Seventh Level as shown in the diagram, Fig. 3.

It has been found that the conveyor can be advanced the 10 ft. necessary for each move in about 30 min., so little time is lost in making the transfer. At the point where the pitch and face chutes meet, two unfilled chocks of square timber are used alongside the pitch conveyor resting on the shale bottom. These chocks can be recovered and they are carried forward as the face advances. So far all timbers have been pulled and reset without loss. The floor is so soft that it is necessary to put short blocks or sills under each prop.

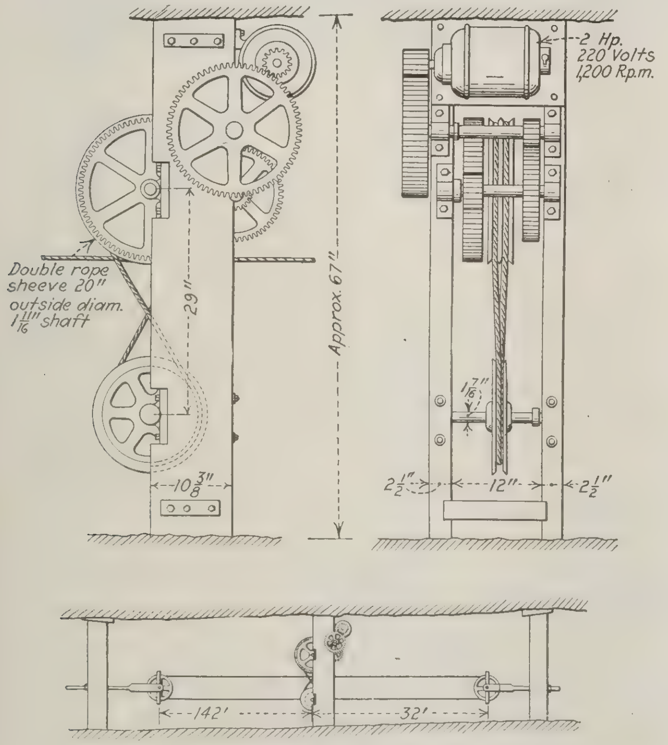

**Fig. 4—Home-Made Car Haul**

With this machine a 2 hp. motor is enabled to spot cars under the chute for loading where control would be difficult if some mechanical means were not employed.

The cars are spotted by a home-made car haul, details of which are given in one of the accompanying illustrations. This car haul as well as the chutes were improvised most skilfully at the shops of the company by Gomer Reese, general superintendent of the Kemmerer Coal Co., who used for that purpose material available around the mines.

Ten men mine and shovel the coal into the face conveyor and one handles the cars beneath the chutes. The entire force thus consists of eleven men. The output in eight hours is about 125 tons. This is not a noticeable saving in the number of men employed but the advantages are not so much in tonnage as in better coal and in a reduction of costs other than those of actual mining. However, the greater percentage of extraction is an important advantage.

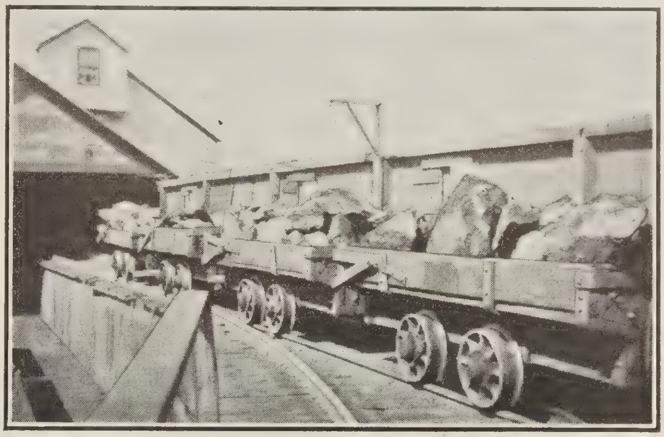

**Fig. 5—Conveyor Coal On the Tipple**

This illustration shows coal loaded by shaking conveyor, as it enters the tipple. The excellent size of the lumps is immediately noticeable. One of the chief advantages of long-face mining by shaking chute is the increased yield of lump coal and the small quantity of fine material and dust that is produced.

The cars are not large, their wheel gage being only 42 in. and their bottoms not being set down over the wheels. They hold about 1½ tons each as loaded by the chute and are not topped by hand. They weigh about 2,200 lb. empty. As the roadways have to be timbered heavily, it would not be advisable to make the cars much wider or higher. It would be necessary to cut heavily into the bottom shale to permit the entrance of a car of any greater height and as the bottom is quite soft and as the cover is heavy, any enlargement of the cross section of the roadway would be undesirable.

The small size of the car does not seem to be an important cause of delay at the chute as the cars can be rapidly and easily spotted for filling. However, if they were larger the same number of trips spotted under the chute would result in a larger production.

Because of the weakness of the floor it has not been feasible to use a scraper. It is feared that even if such a loader were run over a steel plate it would dislodge large quantities of bottom and spoil the product.

In order to make the mine safe against explosions the Eleventh South Level has been copiously rock dusted with pulverized limestone from the Devils Slide in Utah. Barrier troughs also have been installed near the main slope using the same dust. This appears to be dry and in excellent condition to make a curtain of inert material as soon as dislodged.

# First All-Electric Coal Strip Mine Is Saving Northern Pacific $700,000 a Year

By H. E. Stevens
Chief Engineer, Northern Pacific Ry., St. Paul, Minn.

THE FIRST COMPLETELY ELECTRIFIED coal strip pit in the country at Colstrip, Mont., is now busily justifying the Northern Pacific Ry.'s decision to mine coal in that isolated prairie locality. Forty miles of track had to be built to this stripping from the railway's main line at Forsyth, a power line 100 miles long had to be constructed from Billings and a community created at the site but these obstacles were overcome last winter. Big-scale operation under favorable stripping conditions in a huge acreage of 28-ft. coal has been under way for months and is reducing the cost of the railway's locomotive fuel at the rate of at least $700,000 a year.

In prospecting the coal resources tributary to its lines of railway the Northern Pacific, in 1913, made a general geological examination of the large semi-bituminous coal vein in south central Montana, known as "The Rosebud Field." From outcrops and other indications it was determined that this vein underlies an area of approximately 700 sq.mi. in Montana, and an unknown larger area in northern Wyoming, and that the full thickness of the vein was 28 ft. This thickness is maintained over the entire area, except where the bed is eroded or burned out. Fig. 1 shows the location and approximate outline of the field in Montana.

It was also found that the Rosebud vein was closely underlain over practically the entire area by the McKay vein; the parting between the two beds of coal varying from a few feet to 20 ft., indicating that the two measures were really a part of the same deposit.

No reliable estimates are available of the total volume of coal in the two veins, but from this outcrop survey it was calculated that there were at least six billion tons in the Rosebud vein in Montana alone.

Although the Northern Pacific, through its subsidiary, the Northwestern Improvement Co., owned and operated some good mines at Red Lodge, Mont., the possibility of developing a more economical locomotive fuel supply from the Rosebud field was such that in 1917 the chief engineer of the railway was directed to make a thorough exploration and report, covering methods and costs of reaching and opening the Rosebud field, and the comparative value of that coal as a locomotive fuel. This work was completed and report made in February, 1919; the exploration covering 15 sq.mi. in the northerly edge of the field near the head waters of Armell Creek, outlined in black in Fig. 1 on the opposite page.

A complete topographic survey was made of a tract of 15 sq.mi., and sufficient borings put down to determine top and bottom of the coal seam over the entire area, giving in effect a topographic map of the ground surface, top of the coal, and bottom of the coal. All coal having 100 ft. or less of overburden was classed as stripping tonnage, and coal lying at a greater depth than 100 ft. was classed as mining tonnage. The total for the 15 sq.mi. being as follows:

**Through Cut at Colstrip Made by Big Shovel Working Part Time as Dragline**

This was the beginning of the country's first all-electric coal strip pit. The cut was about 7,800 ft. long. Parallel cuts to this are now uncovering swiftly the 28-ft. bed of coal which is shot and loaded out into railroad cars run into the pit on a track laid directly on the coal berm. The pit is expected to save the Northern Pacific Ry. at least $700,000 a year on its locomotive fuel consumed on Montana divisions. This mine, excavated in the boundless prairie of south central Montana, is near the region made famous by the Custer massacre. The historic, Indian-fighting, Big Horn country is directly at the west of the Colstrip coal beds.

| | Tons |
|---|---|
| Stripping volume | 150,000,000 |
| Mining volume (50 per cent recovery) | 90,000,000 |
| Total | 240,000,000 |

The report recommended construction of a railroad up Armell Creek, and the opening of a strip field about 30 miles directly south of Forsyth, Mont.

Five shafts were sunk to and through the coal seam at various locations within the area explored, and from one of these about 400 tons of coal was mined and hauled across country to the railway tracks for actual test in locomotive firing. These tests demonstrated that this coal could be successfully used as locomotive fuel, although it would require some changes in the existing methods of drafting and firing.

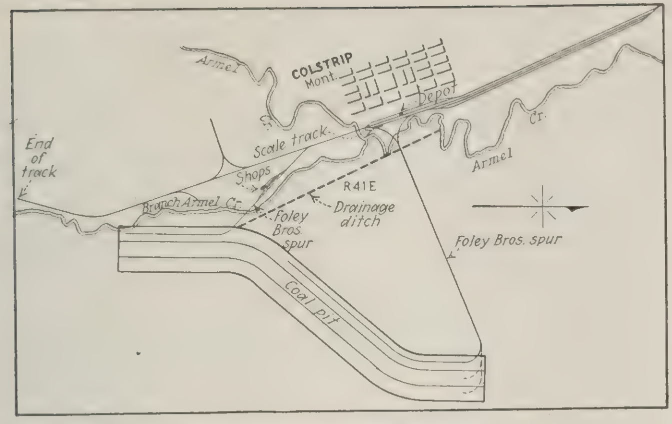

**Fig. 1—Layout at Colstrip**

From this drawing the position of the 8,000-ft. strip pit can be seen with relation to the newly-built village and railroad. The drawing indicates that one through cut has been made and loaded out and that the shovels are working on parallel cuts.

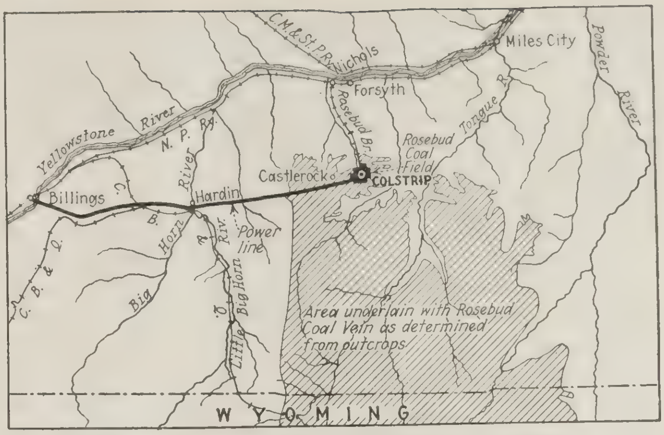

**Fig. 2—General Map of Rosebud Coal Field**

Billions of tons of coal underlie the tremendous area of south central Montana and northern Wyoming, the deposit most available to the Northern Pacific being the 15 sq.mi. at Colstrip, opened by the new Rosebud branch.

Test samples were taken from shafts and drill holes, the average analysis of 48 samples being as follows:

| | Per Cent | |
|---|---|---|
| Loss from air drying | 12.30 | |
| Retained moisture | 11.08 | |
| Volatile combustible | 51.20 | |
| Fixed carbon | 29.94 | |
| Ash | 7.77 | |
| Sulphur | 0.67 | |
| B.t.u. | .... | 10,825 |

In the locomotive test runs comparison with Red Lodge coal was as follows:

| | Red Lodge | Rosebud |
|---|---|---|
| Pounds water evaporated per lb. coal | 5.81 | 4.33 |
| Pounds coal per 1,000-ton miles | 104 | 146 |
| Pounds coal per drawbar hp.-hr | 4.79 | 6.77 |
| Tonnage hauled | 1,794 | 1,783 |

These figures were the average of six round trips over an undulating one-per cent grade with the heaviest class of freight power. From these figures it was determined to make the economic comparison on the basis of one ton of Red Lodge coal being equal to 1.4 tons of Rosebud.

On this basis, and on the further assumption that a railroad to the coal field would develop no additional business of consequence, it was estimated the railway company would make an annual saving of at least $700,000 by substituting Rosebud for Red Lodge coal as locomotive fuel over the territory, Mandan, N. D., to Missoula, Mont.

No action was taken on the report until the fall of 1922, when the board of directors authorized the construction of the branch line and the opening of the field.

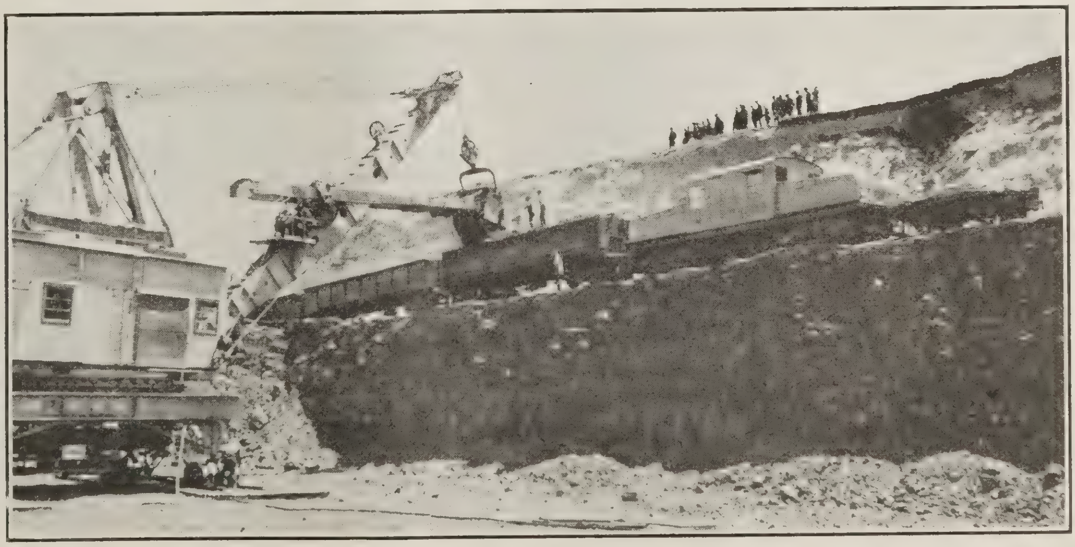
The construction of the line was awarded to Winston Bros., of Minneapolis, and work begun in the spring of 1923. The track reached the coal field in December, 1923. Ballasting was deferred until the season of 1924, and the line was turned over to operation on Sept. 1, 1924.

Meanwhile a small test pit lying in comparatively shallow overburden was stripped with grading machines and about 45,000 tons of coal delivered to the mechanical department for further locomotive tests, for the purpose of determining proper drafting, firing, etc.

The Northwestern Improvement Co. was not equipped or organized to handle a large excavation job, and, therefore, it was decided to open the field by contract. It was thought, however, that it might later be desirable to operate the field by company force, and a 5-yr. limit was fixed for the first contract operation. In order to permit taking the field over without interruption in the operation it was necessary to make some provision in the contract whereby the Improvement company would come into possession of the equipment at the end of the contract. At the same time it was desired to leave the contractor free to select and install the equipment which, in his judgment, would most economically handle the desired output of coal. The contract, therefore, carried somewhat unusual provisions in the way of division between unit costs and equipment costs.

**Loading Out**

The 175-ton shovel picks up coal from the 28-ft. bed already loosened with explosives and discharges it directly into railroad equipment run into the pit on the berm. Ten-car trains are each loaded in a little over an hour. The trains are handled in and out of the pit by 60-ton storage battery locomotives, the largest in coal service anywhere. Chief Engineer Stevens of the Northern Pacific, says these locomotives solved a troublesome problem and have given "excellent service."



Briefly, it provided the contractor should furnish and install the complete plant necessary for the efficient and economical operation of the field, with the exception of standard gage locomotives and 56-lb. rail, which were furnished by the Improvement company and turned over to the contractor.

The bidders were given the results of the borings conducted by the Improvement company over the area to be stripped and asked to name unit prices per cubic yard for common excavation, hard pan, loose rock and solid rock. The estimated quantities of stripping specified varying from 500,000 cu.yd. per year to 2,100,000 cu.yd. per year. Also bidders were to name a unit price per cubic yard for coal loaded into standard open top cars of the railway company. The bidder was required to specify rates per hour for each class of employee which he proposed to use on the work. The improvement company agreed to assume the risk of variations in rates of pay throughout the contract period.

### Contractor to Furnish Proper Equipment

The bidder was also required to name a flat lump sum for the equipment complete, specifying the principal items of equipment contemplated by his plan of operation, but the responsibility for furnishing the proper type of required equipment was to rest solely with the contractor. Payments for equipment were to be made by the Improvement company in ten semi-annual amounts. The equipment included camps and all appurtenances necessary to put the field on a practical and economical operating basis.

In comparing bids, the unit prices bid per cubic yard for the different classes of excavation of overburden were extended into the classified quantities as determined from the borings, and the unit prices per cubic yard for coal loading extended into the estimated quantities of coal. To these sums was added the flat sum bid for equipment, and the wage adjustment necessary to put all bids on the same basic wage scale. The total so obtained divided by 4,100,000 cu.yd. gave the amount per cubic yard the company would pay for coal. This method completely amortizes the equipment in the 5-yr. period.

It is interesting to note that on this basis the difference in estimated total payment for stripping the overburden on the unit prices bid by Foley Bros., as compared with the bid submitted by Winston Bros., was but $6,150 on an estimated volume of 6,300,000 yd. of stripping.

Foley Bros., bid for loading the coal, however, was substantially below the figure named by Winston Bros., and the former firm was awarded the work.

### Question of Water Supply

The preliminary exploration of the field had developed the fact that the question of water supply would become an important one; in fact, there was no dependable surface water supply available, and it was questionable what supply, if any, could be developed from the pit. Because the test shafts had filled with water as soon as they were put down it was thought the drainage ditch from the pit proper would provide an adequate volume of water, although it was known to be of extremeley poor quality for boiler purposes.

The opening of the drainage ditch and of the preliminary test pits developed the fact that no real vein of water was available either above or below the coal seam, and after thorough consideration of the situation it was decided that electric operation presented the only reliable method of handling the field. A power line was built in from Billings, a distance of 100 miles. The Improvement company assuming the cost of constructing the line from Hardin to Colstrip—about half the total distance. Electric equipment was bought for the pit including two 60-ton locomotives for switching. Their performance to date has been entirely satisfactory and solved what had been an extremely perplexing problem in the operation of this field.

Foley Bros. have installed the following equipment: One 350-ton revolving type combination dragline and shovel, equipped with 155-ft. dragline boom with 6-yd. dipper, and 90-ft. shovel boom with 6-yd. dipper; one revolving type shovel equipped with 75-ft. boom and 7-yd. dipper; one gasoline dragline 2½-yd. bucket, 60-ft. boom; one 20-ton locomotive crane; two 60-ton electric storage-battery locomotives; one electric well drill, and two portable type air compressors. Each piece of equipment has been provided with a complete set of spare parts.

A complete machine shop has been constructed, equipped with the following tools, all purchased new for this work: One 20-in. lathe with 18-ft. bed, a 100-ton wheel press, a 24-in. draw cut shaper, a 450-lb. air hammer, cut off saw, band saw, bolt cutter, and a wet and dry grinder. All tools are operated by a direct connected motor and are well adapted for any machine work incidental to the coal field operation.

### Buildings in the Camp

The camp consists of the following buildings: Two 50-man bunk houses, dining hall and kitchen, two-story office with sleeping accommodations for the office force, steam laundry, ice plant, storeroom and store, recreation hall, one 20-stall and one 3-stall garage, septic tank sanitary system, and ten small cottages for highly skilled employees and their families. All buildings are electrically lighted and steam heated from a central boiler plant.

In addition to the contractor's camp, the Improvement company has provided four cottages and one office for its employees, and a two-room school building.

The pit is approximately 7,800 ft. long, and will ultimately be cut to a width of 900 ft. The estimated coal available in this pit is approximately 6,800,000 cu.yd. Of this quantity, Foley Bros.' contract will cover about 6,300,000 cu.yd. stripping and 4,100,000 cu.yd. of coal loading. All but a small quantity of the stripping lies below the 50-ft. contour.

The pit was opened by cutting in the 350-ton machine as a dragline, taking out a through cut about 125 ft. wide on the bottom the entire length of the pit. The smaller machine is used as a coal loader and follows the stripping shovel on the level of the bottom of the coal bed. The loading track is laid on top of the coal.

The sequence of operation from the time the pit was opened follows: The stripping shovel was cut in at the point where the track enters the pit and moved south to the south end of the stripping. It then idled back overland to the point where it first cut in, and moved north to the north end of the pit, followed, of course, by the coal loading machine.

The stripping shovel reached the north end of the cut on July 1. It was then idled back and cut in again having been converted into a shovel. It will again move north, taking a cut 88 ft. wide, casting the spoil over the loading track into the pit from which the coal has been removed.

It was estimated the relative volume of coal and overburden is such that the progress of the two machines would bring them to the north end of the pit simultaneously, but if necessary the intermediate width of the stripping shovel cut will be varied sufficiently to bring about the relative rate of movement required to accomplish this result. The loading shovel will then turn south, loading the coal stripped by the stripping shovel on the northerly cut, the stripper idling back to the original point to renew stripping in a southerly direction.

A meet will similarly be arranged between the two machines at the south end of the pit, which is estimated to be reached, at the present rate of coal consumption, about August, 1926. At this time a full cutting will be stripped ahead of the coal loader, this being the maximum spacing obtainable for single pit operation.

The output of the stripping shovel has been quite uniform for the different classes of material, so that with cross-sections and borings available the estimated location of the stripper on any given date can be predicted with a fair degree of accuracy and meets arranged to suit the coal consumption required by the railway company.

The operation of this field is under the general supervision of C. C. Anderson, general manager, Northwestern Improvement Co., Seattle, Wash. Lochren Donnelly, superintendent, is in direct charge of field operations, with headquarters at Colstrip. The engineering work for the opening and development of the field was done under the supervision of the chief engineer of the Northern Pacific Ry. Co.

---

# Colstrip's Electrical Equipment Is Unusual

**By V. A. Wolcott**
Minneapolis, Minn.

OF THE MANY recent accomplishments in improved railroad operation, few are of greater importance than the opening last summer of the completely electrified open-pit coal mine at Colstrip, Mont., by the Northern Pacific Ry. Co. This is an important event as, for many reasons, it serves as a milestone in the economic progress of this industrial age. It is the first completely electrified open-pit coal mine in this country.

The electrical equipment involves many novel features of design, some of which were demanded by the unusual physical conditions to be overcome in accomplishing the successful issue of this undertaking.

This project, in addition to being an outstanding engineering and economic achievement, is an excellent example of conservation of national resources, by reason of the exclusive use of hydro-electric energy for all power operations.

The uncertain water supply in the field led to electrification. The little water available was alkaline. Steam equipment would, therefore, require either an evaporating plant, which was found to be high both in first cost and operation, or boiled water would have to be hauled in tank cars from Forsyth, a distance of 35 miles. After thoroughly considering the final cost per ton of coal mined and the continuity of mining operations, electrically operated equipment was deemed best adapted for that field. A power contract was made with the Montana Power Co., which extended its 55,000-volt, three-phase, 60-cycle power line from Billings, Mont., to Colstrip, a distance of 100 miles.

A Marion Model No. 360 electric stripper with a 155-ft. dragline boom and 6-yd. bucket and a 90-ft. shovel boom with a 6-yd. dipper was purchased. This machine weighed 475 tons including 100 tons of counter-

**Off Comes the Cover**

Standing on the bank is the huge stripping shovel which, with its counterweight, weighs 475 tons. This gigantic machine, assembled and put into service on the "roaring prairie" of southern Montana, is doing a tremendous job. Working first as a shovel and then as a dragline it has opened up the 7,800-ft. Colstrip pit, removing cover averaging 40 ft. from the huge deposit of 28-ft. coal which the Northern Pacific Ry. is mining for its own use to replace, largely, the coal it has been mining for years from underground operations at Red Lodge, Mont. Because of water shortage the whole strip mine is electrically operated.

weight. Standard General Electric Co.'s Ward Leonard, direct-current shovel control and power apparatus were used in its operation.

The coal loading shovel is a Bucyrus Model No. 175-B weighing 220 tons with a 75-ft. boom and a 7-yd. dipper, and has Ward Leonard, direct-current shovel control and apparatus. The motors on this shovel have separately excited shunt fields, which is a new and improved feature in electric shovel operation. The loading shovel loads coal directly from the vein into standard steel coal cars of 50 tons capacity.

The loading track is situated on the top of the coal vein and extends about 8,000 ft. along the edge of the coal pit next to the ground being stripped. The stripper boom, in depositing earth into the adjacent coal pit, continually works over this track. This fact largely determined the type of locomotive and haulage system used to deliver the coal trains from the shovel to Colstrip.

Trolley and third-rail systems, oil-electric, gas-electric, and electric storage-battery locomotives were considered. The electric storage-battery locomotive was wisely chosen, because it required no trolley which might come in contact with the stripper boom, and no third-rail offering a like menace. It was reliable, because it was rugged and simple in construction and operation. It was economical of power, low in maintenance, and either comparable in price with some types or cheaper than others. Two 60-ton, 175-volt General Electric storage-battery locomotives were purchased using lead storage batteries.

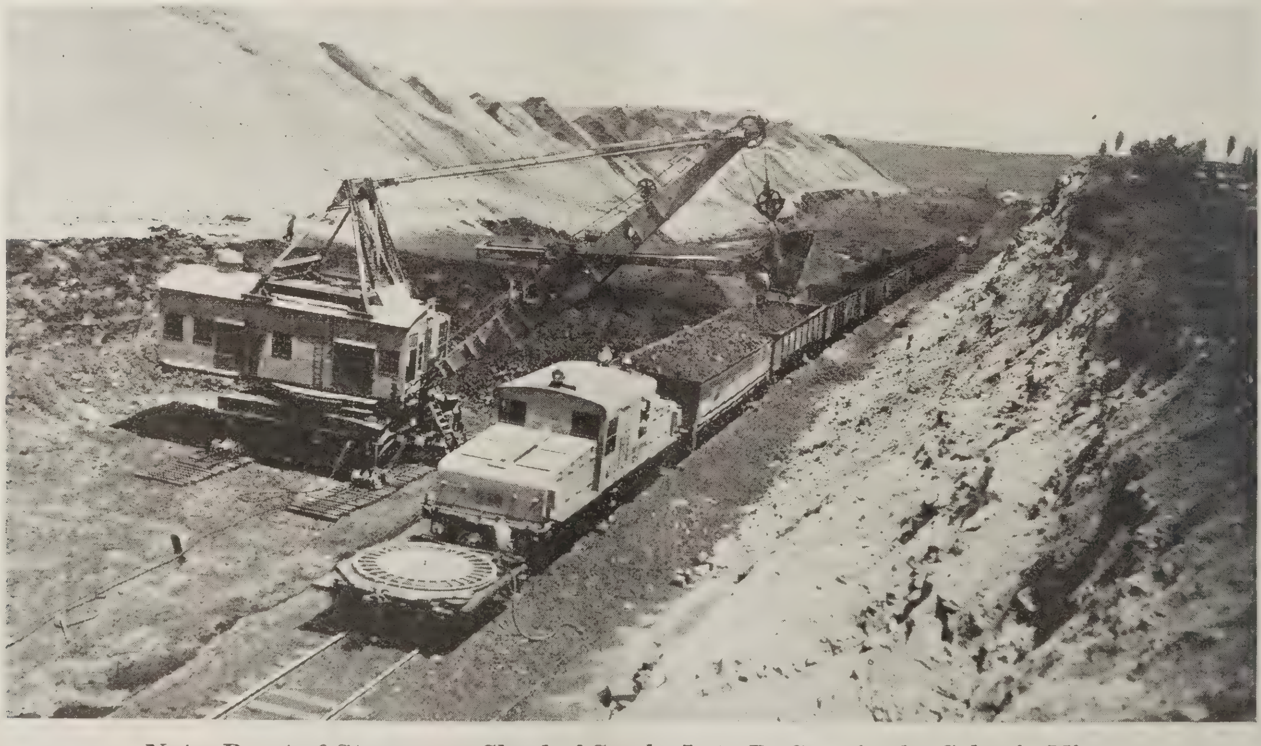
The nature of the mining operations again determined the design of the locomotive. The shovel, working in the coal which previously had been blasted, loads a 55-ton car in 6 min., or a 10-car train in approximately 1 hr. This affords time for charging the locomotive batteries while the shovel is loading the train. Each locomotive has its own motor-generator charging set in its cab.

The locomotive pulls the empty train into position for loading. A small truck on which is mounted a motor-operated cable reel is then coupled to the front of the locomotive. The cable is plugged into a socket in the side of the locomotive cab, and the other end connects to a bank of transformers on the shovel. The charging operation continues even while the locomotive moves the train from time to time in spotting the cars at the shovel. When the train leaves the shovel the cable-reel truck is disconnected from the locomotive and coupled to the next incoming locomotive.

The contractors are now equipped to produce easily an average of 3,000 tons per shift, and are prepared to operate 24 hr. per day, if increased output is desired. The original plans of the Northern Pacific were to use 300,000 tons of coal the first year, increasing the railroad's requirements until, at the end of 5 yr., it would be burning 1,400,000 tons per year. The economical results obtained by the use of this coal have encouraged the company to increase as rapidly as possible the number of locomotives using it, and it may be using 1,200,000 tons annually in the near future.

## Shooting Is Heavy at New Colstrip Mine

How explosives are used in Colstrip is described by E. H. Simpson in the current issue of the du Pont Magazine. Mr. Simpson says: "In shooting the overburden, all holes are chambered with ammonia dynamite, 60 per cent strength, sufficiently to permit loading ½ lb. of railroad grain blasting powder per cubic yard of overburden, which includes the 'wash' as well as the



**Not a Burst of Steam or a Cloud of Smoke Is to Be Seen in the Colstrip Mine**

The photograph shows the shovel loading coal from the 28-ft. bed directly into cars. The 60-ton battery locomotive is accompanied by its cable-reel car. By means of this cable and the motor-generator set in the cab the locomotive recharges its batteries during each of the 1-hr. periods when the shovel fills a 10-car train. When the train is loaded the locomotive sets out the reel car for the next locomotive's use, and hauls its train out of the mine to the Northern Pacific's track nearby.

**Sixty-Ton Storage Battery Locomotive**

This type is used by Foley Bros. to handle 10-car trains of railroad equipment into and out of the pit for direct loading by the shovel.

solid rock. Each hole is primed with one electric blasting cap in one 1¼x8-in. cartridge of ammonia dynamite, 40 per cent strength. Large areas are fired simultaneously, using either a blasting machine or power current.

"With the coal uncovered, the loading shovel is carried on a track in the center of the pit and cleans up a face 112 ft. wide at the top and 88 ft. wide at the bottom, with the center of the face 25 ft. in advance of the corners at each side. This semi-circular face is cut to the radius of the shovel.

"To shoot the 28-ft. coal, one line of six holes 17 ft. apart is drilled on the same curvature as the face 21 ft. back, and two additional holes along each rib or side line of the cut. All holes are drilled to a depth of 25 ft. or within 3 ft. of the bottom of the coal vein. All holes are chambered, and the explosive charges are confined at the bottom of each hole.

"Conditions vary from dry to extremely wet. Gelatin dynamites, 25 per cent strength, are used when the work is wet. Each hole in the back row is loaded with 40 lb., and the side or 'crib' holes with 18 lb. each, making a total of roughly 300 lb. per round. When the work is dry, blasting powder, R.R.P. granulation, is loaded, two kegs to each back hole and one keg to each rib hole, or a total of 400 lb. All holes are primed with electric blasting caps and fired simultaneously. In either case the explosive charge breaks up the coal sufficiently for economical loading."

This community, Colstrip, says Mr. Simpson, where one's vision is checked only by distant hills, and where a year ago the only evidence of civilization was a lone log cabin, is today a hustling coal town.

---

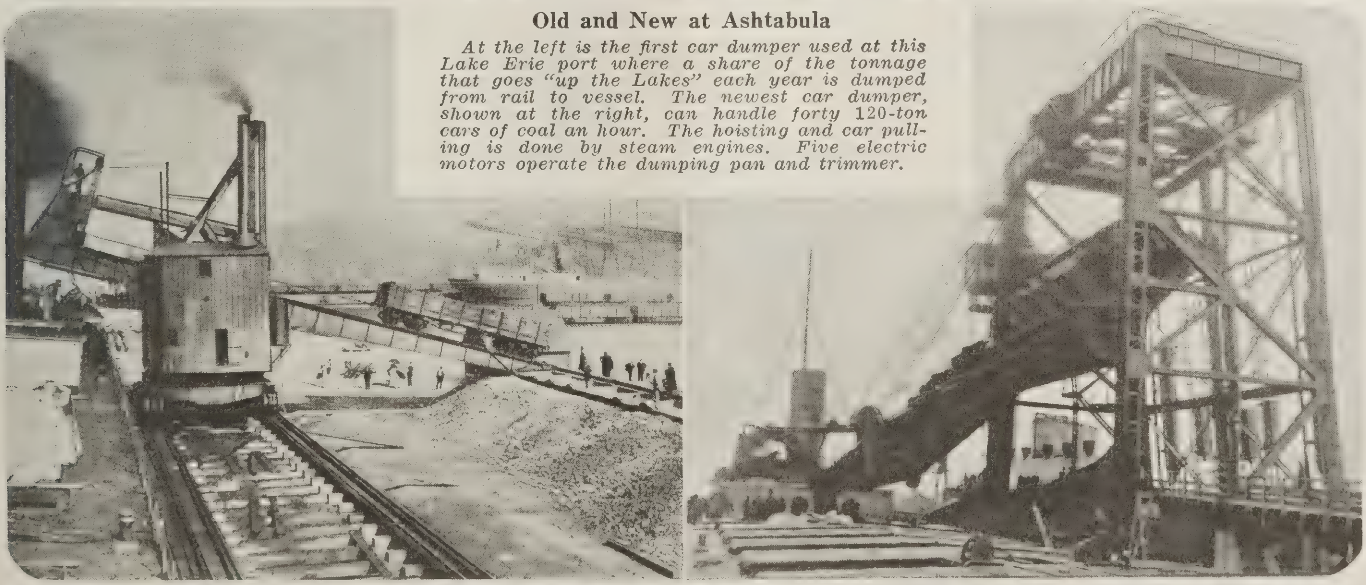
## New Paste Promises Decided Battery Improvements

Heretofore one of the chief disadvantages inherent to the storage battery has been its great weight in comparison with its capacity for storing energy. But little improvement in this regard has been made lately.

Within the comparatively recent past, however, a new substance or binder for the lead salts employed in battery manufacture has been developed in England, and accumulators made with the new paste are now undergoing exhaustive tests in London. While the complete results of these trials are not and cannot be fully known until the tests are concluded, enough has been done to justify certain claims of superiority for the new substance and the batteries in which it is used. Both in first cost and capacity the new batteries have great advantage over the older well-established types.

Improvements of the new battery over the old lie chiefly in the plate employed. This combines large capacity with an ability to withstand high rates of charge and discharge. The new binder permits the manufacture of a plate of great mechanical strength and porosity as well as freedom from sludging. The strength and flexibility of the active elements are such that the grid serves practically as an electrical collector only.

Results of the tests so far conducted would indicate that the cost of the new battery will be appreciably less than that of its predecessors; that its capacity for a given weight will be at least 35 per cent greater; that its charging time will be shorter and its life longer, and that it evolves no dangerous or harmful fumes. All of these foreshadow traction, transportation and lighting possibilities heretofore unobtainable through the use of electrical accumulators.



**Old and New at Ashtabula**

*At the left is the first car dumper used at this Lake Erie port where a share of the tonnage that goes "up the Lakes" each year is dumped from rail to vessel. The newest car dumper, shown at the right, can handle forty 120-ton cars of coal an hour. The hoisting and car pulling is done by steam engines. Five electric motors operate the dumping pan and trimmer.*

# Better Underground Lighting Aids British Mining

### Advances in Method and Equipment Have Been Made to Reduce Cost of Coal by Lowering Accident Rate and Raising Efficiency

By **James Cooper**
Assistant Professor of Mining, Heriot-Watt College, Edinburgh, Scotland

Efforts are being made in the British coal fields to lower extraction costs. Better illumination is generally regarded as one underground factor contributing to this reduction. Illumination recently has been the subject of extensive research by a government committee which has issued many valuable reports.

In Great Britain, out of the 800,000 safety lamps used, about 350,000 are of the electrical type and the remainder of the oil type. The electric lamps consist of two classes, namely the hand and the cap lights.

In Scotland where many open-flame cap lamps are used, and where in gassy mines the electric cap lamp is rapidly being installed, the output per man is higher than in any other area of the British coal fields.

The evidence clearly shows that a cap lamp is more advantageous than a hand lamp, the reason being that when the lamp is on the cap it is in the position in which it can most effectively assist the eye of the underground worker.

In deep mines, owing to high temperatures, the men frequently wear only shoes and a loin-cloth, and with the battery of the cap lamp placed on the hip and secured by a belt, small pieces of mineral get between the skin and the cloth so that the battery chafes the wearer with every movement of the body.

According to recent statistics the 1,200,000 men engaged in mining have 180,000 accidents of sufficient severity to cause them to absent themselves from work for more than 7 days. How does the standard of illumination in the mines affect these figures. It is accepted by all who have had underground experience that the stronger the light the better it will enable men to see the roof and so avoid the ever-present dangers of falls of slate; that all actions will be speedier as the objectives are more easily seen, and lastly, that there is more eye strain when the perspective is inadequately illuminated. Thus, the quality of the illumination will affect the accident rate due to falls of roof and coal, this class accounting for 50 per cent of the total accidents occurring in British mines.

## ENABLES BIGGER PRODUCTION

With the greater activity that improved illumination renders possible, more coal is produced. Furthermore, ineffective lighting has a serious effect, as the prevalence of nystagmus already costs the industry over £1,000,000 a year. At the same time this disease brings undesirable social evils in its train, the victim becoming irritated at his inability to work at ordinary jobs. Lastly, it opens up an avenue for malingering or for the suspicion that the real victim of the disease is only feigning an inability to work.

The passing of the Order in 1913 requiring that only "approved types of lamps" be used in mines where safety lamps are employed, caused lamp makers to tackle the problem of providing a high-grade article.

When the war came a few months later, progress naturally was delayed, but on the cessation of the struggle, the subject was vigorously attacked and during the past few years the improvement in lamps has proceeded rapidly. Two factors focussed attention on illumination: (1) The high production cost per ton; (2) the growing cost of nystagmus. Compensation rose from one penny per ton in 1913 to 3.6d. in 1924.

The problem could best be attacked in two directions, first, by the formation of a strong committee to initiate and make researches, basing their reports on the results, secondly, by encouraging new ideas in the construction of both oil-flame and electric safety lamps.

The findings of the committee have been published in a number of reports in which the most important facts are (1) that the illumination given by lamps, both oil and electric, used underground, should be greatly increased; (2) that 20-mesh gauze should be used in place of the 28-mesh fixed by Davy over a century ago. This change of gauze mesh, which has been approved by departmental authority, is an epoch-making advance for the mining industry and in more normal times would have elicited much praise from all parties in the coal fields.

## LARGER MESH GAUZE MORE EFFICIENT

Its 400 apertures to the square inch of gauze surface, in place of the 784 apertures customary in the old type of gauze, increases the quantity of air admitted to the flame. According to the report of the committee, the illumination, which for the same lamp was 0.5 cp. with the 28-mesh gauze is increased to 0.93 cp. with the 20-mesh gauze.

The report advocates also a 4-volt battery in place of the present 2-volt, but this can be obtained by a reintroduction of the alkaline cell of the Edison type, as the lead battery still in general use would be much too heavy if its capacity were doubled.

In recent months the activities of the lamp makers have been no less fruitful. Several firms are now constructing the combustion-tube oil-flame lamp made familiar many years ago by the Hailwood company. Recent tests have shown that this device gives satisfactory results, and the addition of the 20-mesh gauze will raise its candlepower to such a degree that it will be a formidable competitor to the electric lamp as at present constructed.

The shadowless electric lamps now being developed have movable reflectors, the standards and cap that shaded the glass in lamps of the old type being removed. Attention is also being directed (1) to devices for rapidly changing lighting bulbs in the lamp room, (2) to the replacement of a liquid electrolyte by an unspillable jelly, (3) to the design of better contacts and of a rigid position for the battery and (4) to the choice of the best kind of glass surface to prevent glare.

The last point is most important, canary-colored, dioptric, and frosted globes all being tried. The frosted glass will probably be found the most suitable, as there is uniform illumination and no shadow effect.

Individual collieries are also initiating new departures. One mine in the Scottish area, having a thick seam and a good roof, has suspended lamps along the machine-cut face.

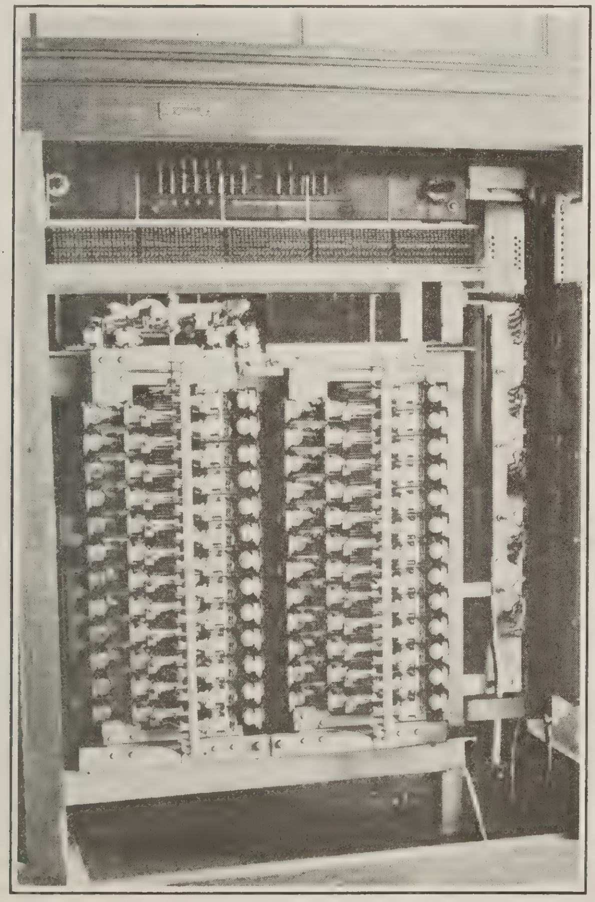
This installation is in a deep mine worked with open-flame lamps. The current is transformed from 500 to 50 volts in an oil transformer, located near the working face, and is led by cab-tire cable, tappings for lamps being provided at 10-ft. intervals. The lamps are of 25 cp. and have 30-volt metallic filament with frosted glass globes encased in the usual underground type of protected, hermetically-sealed fittings. This installation is much appreciated by the men at the face, and a large tonnage per man shift is being attained.

The subject of mine illumination in the past has received little skilled attention, but the present economic stress has made the effort to advance it almost national. There is now, fortunately, proper recognition of its importance. Operators not only recognized its influence on production costs but also the fact that it has much bearing on the social well-being of underground workers.

## Telephone Problems Are Solved by Automatic System

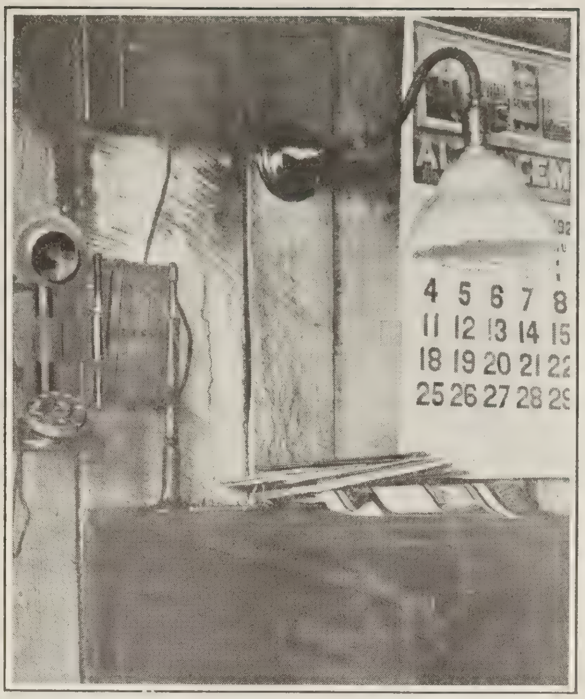
Inadequate telephone service is common at many mining operations. The usual faults are, too few phones, too many phones on a single line, or a lack of night switching service. At those isolated mines which have but one line connection with a public service telephone company, it is the practice for the coal company to install a number of telephones of their own. These are usually of the magneto type. If fifteen to twenty of this type of phone are connected to one line the service is rather unsatisfactory because of the annoyance of frequent ringing and because this number is near the limit that can be made to operate on one line.

With but eight to ten phones on a line, this simple system is satisfactory except for the fact that there is a lack of privacy in the conversations. To have privacy between certain phones requires a separate line for those phones, and this in turn requires the installation of duplicate phones, or of a switchboard. The manually operated switchboard is not entirely satisfactory because of the expense of employing operators. On account of this expense, but few coal companies provide 24-hr. switching service. There is an operator at the board for ten or twelve hours but it often happens that telephone service is badly needed during other hours especially when an emergency arises.



**Provides All-Night Service**

This automatic telephone switchboard is that used by the Raleigh Coal & Coke Co. at Raleigh, W. Va. The entire switching mechanism is contained in a cabinet about the size of a four-section bookcase.



**An Unusual Sight in a Mine Shop**

The calling dial can be seen on the base of the transmitter stand. The automatic phone is always ready for service and there is no waiting for an operator.

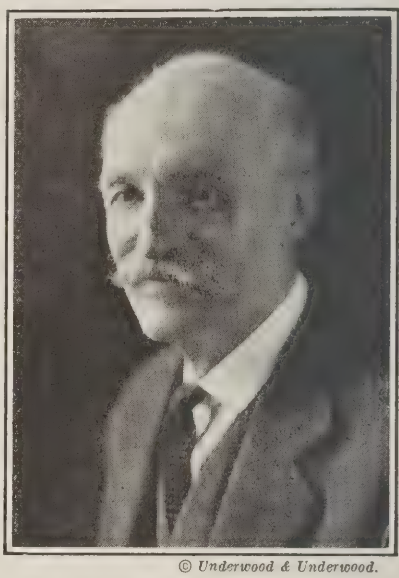
Because of these difficulties in obtaining an economical yet satisfactory telephone service for an isolated mining operation, some of the larger coal companies have installed automatic telephone systems. One example of such an installation is that of the Raleigh Coal & Coke Co. at Raleigh, W. Va. This installation, which consists of an automatic switchboard and approximately fifty phones, has now been in service for over four years and in that time has demonstrated conclusively that it is the only satisfactory and economical system for a mine operation. The service meets all requirements for the twenty-four hours of the day, yet there is no expense for operators.

It is true that the automatic switchboard is more complicated than the manual type, however it has been perfected to a point where there is little chance for difficulty. R. B. Holmes, electrical engineer for the Raleigh Coal & Coke Co., states that he has experienced little trouble with the automatic system. He makes it a rule to inspect the switchboard once each day. At the time of this visit he also gives the storage batteries any necessary attention.

Because of the fact that there is always a voltage on the line and because of the liability of line trouble inside of a mine, the automatic phones are not used inside. Instead, magneto phones with no connection to the automatic system, are installed between the inside and the repair shop on the outside.

# News Of the Industry

## Peace Move in Anthracite Strike Foreseen When Pinchot Invites Lewis and Inglis to Conferences



© Underwood & Underwood.

**Gifford Pinchot**

Governor Gifford Pinchot of Pennsylvania has once again stepped into the anthracite strike picture with invitations to John L. Lewis, president of the United Mine Workers, and W. W. Inglis, president of the Glen Alden Coal Co. and chief of the operators' section of the scale committee, to confer with him. As was the case with the Milford conferences several weeks ago, the Governor will meet the opposing leaders in separate parleys. He journeyed from Harrisburg to Philadelphia yesterday to sound out Mr. Lewis and expects to talk with Major Inglis at the Capitol today.

This latest development follows closely upon activities of the Rev. John J. Curran, of St. Mary's Roman Catholic Church of Wilkes-Barre, who discussed the situation last week with Mr. Lewis and Vice-President Philip Murray. Father Curran's name has been linked with the suggestion that a basis of settlement might be found in a flat 5 per cent increase and a "modified" form of the check-off. That the operators had proposed or entertained such a proposition was denied by them. At the conclusion of his talks with Messrs. Lewis and Murray, Father Curran declared that the next move was "really up to Governor Pinchot." He added that he believed the Governor would call both sides together "before very long."

### Criticizes Operators

Commenting upon the outlook as he saw it, Father Curran said:

"Perhaps the operators are a little stubborn. During the past several weeks I have heard things that make me think they are. The men are fair. They are not arbitrary. They are willing to stand by the public, but do not want to concede all their rights."

This theme was re-echoed by Mr. Lewis at an address at Nanticoke on Nov. 5. The head of the mine workers asserted that the miners did not relish strikes, but had been forced to call a suspension to protect their rights because of the "unreasoning" attitude of the producers. "There has been no change in the attitude of the operators, no change in their spirit of resistance, and no change in their policy to take all and give nothing." Mr. Lewis stated that he had had a recent conference with Major Inglis. This conference was arranged through an undisclosed third party. No details as to what took place were volunteered by either of the conferees.

In the meantime, as told elsewhere in this issue of *Coal Age*, an active campaign to replace anthracite with semi-bituminous coal is under way in New England, notwithstanding the fact that stocks of hard coal in the hands of the consumers and average reserves in retail yards probably are larger than in any other section of the country. Some splint coal also is moving into New England for domestic purposes despite the absence of through rates.

### Urge Buying of Soft Coal

In New York, public authorities are urging consumers whose stocks of hard coal are low to put in a supply of bituminous. The report of John Hays Hammond to the President that the reserves of anthracite now available would last at least two months, it was pointed out, was statistically correct, taking the coal-burning section as a whole, but that offered no comfort to the householder who had no anthracite in his cellar. "Those in need," remarked George F. Eltz, a member of the New York Coal Commission, "are in no less a predicament because of the safety of some one else."

### *Broadens Inquiry on Rates On "Substitute" Fuels*

The general investigation ordered by the Interstate Commerce Commission into rates on anthracite and other fuels to New England and Middle Atlantic States has been further broadened to cover:

(1) Joint rates and through routes on splint and high-volatile coal from Kanawha and Coal River fields;

(2) Extension of recently established rates on prepared coal to all sizes of low-volatile;

(3) Establishment of rates from semi-anthracite mines in Virginia.

A hearing on these questions will begin before Commissioner Campbell and Examiner Koch of the Interstate Commerce Commission in the rooms of the Merchants' Association, New York City, this morning at 10 o'clock.

The anthracite situation will be discussed next Tuesday by Ellis Searles, editor, *United Mine Workers Journal*, and Walter Gordon Merritt, general counsel for the Anthracite Operators' Conference, at a luncheon of the committee of the Department of Industrial Relations of the National Civic Federation at the Lawyers' Club, New York City.

At a recent meeting of the district board of the United Mine Workers at Scranton a decision was reached against granting the petition of certain washeries in this region to turn out coal and sell the same to schools. The labor leaders went on record as opposing the production or shipment of any coal during the anthracite suspension. About a week before this decision was arrived at permission was granted the Traders' Coal Co., at Plains, to sell 1,500 tons of coal to the public schools of Plains township.

All the surplus coal in stock at the Hauto storage yard has been sold by the Lehigh Coal & Navigation Co. About a week ago there was about 100,000 tons in small sizes at this plant but this has now been cleared up.

Now that the cold weather is putting a stop to work on highways in the hard-coal region many anthracite miners who have been working since the strike started will be thrown out of jobs. This condition is expected to result in many of the rank and file launching efforts to have their leaders resume wage negotiations with the operators.

# West Virginia Smokeless Producers Plan Campaign to Capture New England

**By Sydney A. Hale**

Special Contributor, *Coal Age*,
New York City

First steps in an educational campaign to capture the New England domestic market were taken Nov. 6, when a meeting of the Smokeless Coal Operators' Association of West Virginia, held at the Copley-Plaza Hotel, Boston, Mass., authorized the immediate establishment of a coal service bureau in Boston. In this way the semi-bituminous producing interests of southern West Virginia hope to use the anthracite strike as a means of permanently weaning away a large part of the New England domestic trade from the use of hard coal.

The primary functions of the bureau will be to teach household consumers how to burn low-volatile coals successfully, to handle complaints received by retail distributors from customers experimenting with this fuel, to police shipments to prevent the sale of coal from other districts as West Virginia smokeless and to co-operate with the retail trade and with the various quasi-official and commercial bodies now functioning in New England as a result of the anthracite strike.

Robert H. Gross, president, White Oak Coal Co.; R. L. Wallace, Boston representative of the Pocahontas Fuel Co., and Charles P. Hutchins, Boston representative of W. C. Atwater & Co., have been named a Special New England Service Committee to handle all questions with respect to the creation, personnel and scope of the bureau. The cost of the bureau will be financed out of the funds of the association.

If the Boston bureau proves as successful as its projectors anticipate, supplementary service units will be established at Springfield and Worcester, Mass.; Providence, R. I., and New Haven and Hartford, Conn. Contingent upon the success of the efforts now under way to persuade the Interstate Commerce Commission to direct a more favorable all-rail basis to New England points on lines other than the New York, New Haven & Hartford R.R., additional bureaus are planned. Should the Commission extend the new rates to cover the all-rail shipment of mine-run, still greater expansion is in view.

The question of all-rail rates on mine-run and the application to open up more gateways to the all-rail movement will come up at a hearing to be held in New York City today before Commissioner Campbell. Establishment of a reasonable all-rail basis on mine-run, say the operators, would enable the producers of low-volatile coal from West Virginia to guarantee a monthly minimum of 450,000 tons, instead of 135,000 tons, as is the case while the rates are limited to prepared sizes.

The decision to establish the service bureau was the outgrowth of the activities of the advertising committee of the association. This committee, with Holly Stover, Chicago, as chairman, had been making a study of general advertising as a basis for recommendations on a national publicity campaign. The possibilities of entrenching smokeless in the New England market, however, and the representations made to the operators of the present necessities of that section of the country convinced the committee that any national project should be held in abeyance while a special, energetic drive was made on New England.

The operators' association, at its regular monthly meeting, which was shifted to Boston to give the members closer contact with the situation, unanimously approved the proposals of the Stover committee. It also heard Eugene C. Hultman, chairman of the Massachusetts Commission on the Necessaries of Life, who substituted as a speaker for Governor Alvan T. Fuller. The Governor, in expressing regret at his inability to be present, wrote the association a letter in which he reiterated that New England was in a revolt against anthracite.

"If you producers of smokeless coal," he said, "can restrain your greed; if you can disregard the present as a gambling opportunity to take advantage of the public's necessity; if you will adopt an honest and liberal and considerate policy, you have a wonderful opportunity to entrench yourselves in this New England market."

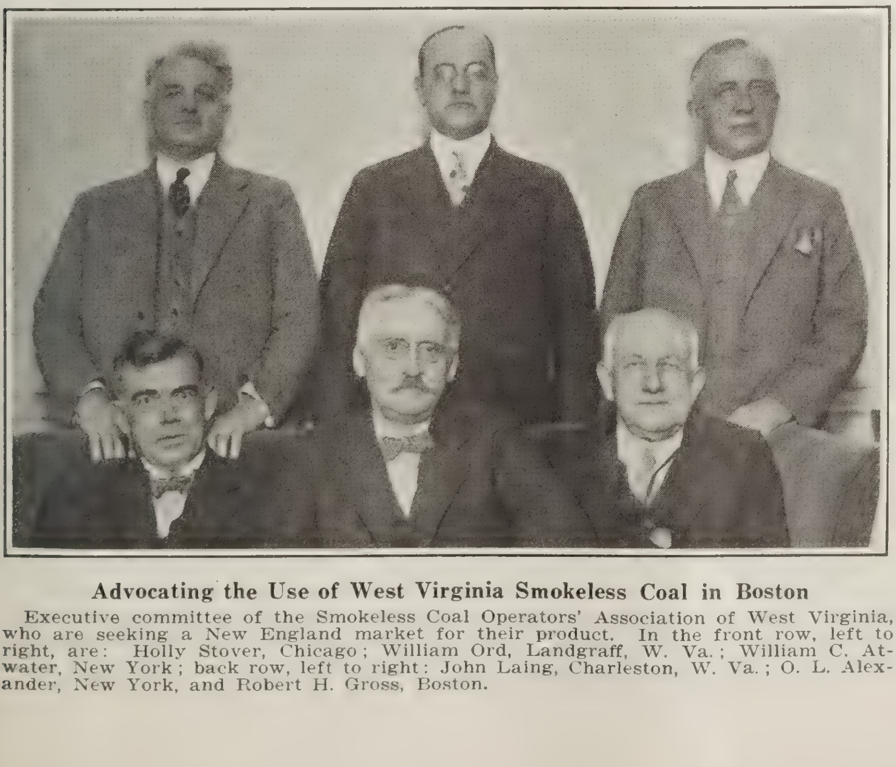
Mr. Hultman stressed the same theme. If prices are boosted, he declared, until retail quotations are almost as high as on anthracite, "and you are the only people who can prevent it, it means that we are going to have a flash in the pan, the people will feel sore and be disgusted with the whole business and demand that the government control the coal industry, and the householder will go back to anthracite the moment the strike is over. I want to help anyone who wants to help us. You have volunteered to be our fuel savior in the present emergency. In the past other fuel saviors have perhaps saved our lives, but in the process they have taken our pocketbooks."

The association met this plea on prices by adopting a resolution condemning the pyramiding of profits in resales. The resolution recited that it had been reported that smokeless had been resold as many as five times between the mines and the final purchaser, resulting in unreasonable prices to the consumer and unjust condemnation of the operator.

### Will Work with Retailers

Vigorous denial of the intimation that the West Virginia smokeless producers will go into the retail coal business in New England if the established dealers do not cooperate fully in the present campaign to sell semi-bituminous coal in the Northeast was made by Robert H. Gross, chairman of the Special New England Service Committee of the Smokeless Coal Operators' Association of West Virginia, in a statement to *Coal Age*.

"The matter of retailing coal by the association or any of its members," declared Mr. Gross, "has not been discussed or considered and we are glad to take opportunity of denying these unfounded rumors. It is the purpose of the West Virginia operators to sell our coal through the recognized channels, of which the present retail dealer is an all-important factor, and we know that the retail dealer will function just as effectively in this present emergency as he has in the past."



**Advocating the Use of West Virginia Smokeless Coal in Boston**

Executive committee of the Smokeless Coal Operators' Association of West Virginia, who are seeking a New England market for their product. In the front row, left to right, are: Holly Stover, Chicago; William Ord, Landgraff, W. Va.; William C. Atwater, New York; back row, left to right: John Laing, Charleston, W. Va.; O. L. Alexander, New York, and Robert H. Gross, Boston.

## Two Oklahoma Mines Reopen At 1917 Scale

The Osage Coal Co.'s mine No. 5, at Krebs, Okla., opened for work Nov. 4 with a small force of laborers, it was reported from the office of the company. The company is one of several in this area that have been able to hire enough men on the 1917 wage agreement to operate since Federal Judge R. L. Williams issued an injunction that prohibits striking miners from picketing with such large forces near the entrance of the mines. Osage mine No. 5 has been closed since Sept. 1, when the general strike of union men in District 21, was issued by William Dalrymple, president of the organization.

The large Wise-Buchanan mine at Henryetta also opened last week on the 1917 scale, according to information received from that town. The mine at full capacity can employ 200 men. It was reported that fifty showed up for work the first day mining operations were resumed.

---

## To Open Oklahoma-Arkansas Mines at 1924 Scale

Several important mines in the Oklahoma-Arkansas coal fields are to reopen immediately on contracts calling for the 1924 wage scale, it has been announced by William Dalrymple, president of district No. 21, United Mine Workers.

The Central Coal & Coke Co., operating mines in eastern Oklahoma and western Arkansas, is said to be one of the larger properties gained over by the union. One of the properties is at Calhoun, near Poteau, but the largest is said to be the Jenny Lind mine, in Arkansas. Approximately 315 miners will be employed in the Jenny Lind mine, according to a telephone conversation with Superintendent Boyd, says Dalrymple.

The Buck Creek Coal Co., operating mines near Panama, Okla., also will open under the new scale, union officials announced. Several other contracts are being negotiated, according to statements of the same officials.

### *Bethlehem Corp. Mine Opens at 1917 Scale*

The Bethlehem Mines Corporation resumed operations at the Marianna mine, near Bentleyville, Pa., Nov. 5 with a force of 46 men, which was increased to 150 the next day. Unofficial reports said the company had brought in a total of 400 men to work the mine, which is being started on the 1917 scale. This mine had been idle more than a year. The company owns many other large mines in the Pigeon Creek Valley and is expected to open others on the same wage basis. The mining company is a subsidiary of the Bethlehem Steel Corporation and the superintendent reports directly to Johnstown.

No disorder marked the opening, but Sheriff Otto Luellen, of Washington County, was prepared to cope with any situation that might arise, as the mine is located in the heart of a strong union district.

### *Survey of Coal Stocks On Dec. 1?*

A survey of coal stocks as of Dec. 1 is being contemplated by the Department of Commerce. Although a definite decision has not been reached, C. P. White, Chief of the Coal Division, announced on Nov. 7, the proposal is under consideration. The last survey was of June 1. Mr. White plans to put in operation, eventually, a program for quarterly surveys. Should a survey as of Dec. 1 be taken, it probably would be between Jan. 5 and 15 before the data would be ready for publication.

In the McAlester-Hartshorne-Wilburton field practically all coal is being mined open shop. The larger mines report larger working forces. Operators declare that 165 men are at work at Rock Island mine No. 12, at Hartshorne, and Rock Island mine No. 10 also reports gains in its working force. Strikers, however, declare that none of the workers will accept work at the terms offered by mines operating non-union.

---

In September 931,462 tons of coal was mined in Colorado, as compared with 939,816 tons in the corresponding month of 1924. Production during the first nine months of this year totaled 6,841,651 tons, or 388 tons less than was produced during the corresponding period last year. State Coal Mine Inspector James Dalrymple announces. An average of 11,477 men have been employed in and about the coal mines of the state so far this year, and the number of days worked per mine has been 126.9. The number of men employed in September was 11,003.

## Montour No. 10 Resumes At 1917 Scale

Operation of mines under the 1917 wage scale by the Pittsburgh Coal Co. came a step nearer Pittsburgh proper Nov. 9, when the company resumed operations at Montour No. 10 mine, at Library, 10 miles from the city, on the Montour R. R. The pit was opened with 41 men at work.

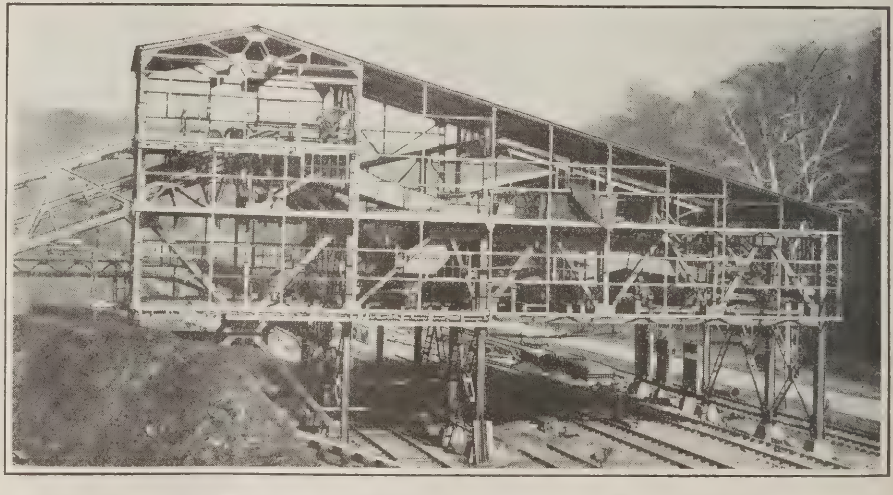
The company now has a total of four mines working on the 1917 scale in the Pittsburgh district, one in each of these counties: Allegheny, Fayette, West Moreland and Washington. With the opening of the mine at Library the company has 749 miners digging coal in the Pittsburgh district and 500 men at Pomeroy, Ohio, all on the 1917 scale.

It is not expected that any coal will be loaded at the Montour mine for several days, as the intervening time will be occupied in cleaning up. Montour No. 10 is one of the newest and most up to date plants of the company, producing a high grade gas and steam coal. The tipple was constructed in 1919. It is planned to bring the mine up to a daily production of about 2,500 tons and to employ 500 men. The mine was closed down in April, 1925. Twenty deputies of Sheriff Woodside of Allegheny County guard the mine.

The Pittsburgh company now has thirty-six idle mines in the Pittsburgh district and the company again emphasizes that any of them will be opened as soon as a sufficient number of men express a desire to return to work.

---

The American Mining Congress has appointed the following committee to consider the use of structural steel for mine timber: H. W. Montz, Lehigh Valley Coal Co., Wilkes-Barre, Pa.; J. M. Clark, the E. E. White Coal Co. Glen White, W. Va.; M. D. Gibson, Bertha-Consumers Co., Pittsburgh, Pa.; D. W. Blaylock, Madison Coal Corporation, Glen Carbon, Ill.; F. H. Frazier, Maher Collieries Co., St. Clairsville, Ohio; R. L. Twitchell, Carnegie Steel Co., Pittsburgh, Pa.; Geo. J. Hahn, Lorain Steel Co., Johnstown, Pa.; Geo. O. Richardson, Bethelehem Steel Co.



**Warden Tipple of Pittsburgh Coal Co. Under Construction**

The Pittsburgh Coal Co. is embarked on a program of concentration and reconstruction that involves the erection of large units. This is the first fruit of this program which will result in cheaper and better coal.

# Thinks Anthracite Strike Will Make Soft Coal Universal Domestic Fuel; President Urged Not to Interfere

**By Paul Wooton**
Washington Correspondent of *Coal Age*

The President has been informed in detail by John Hays Hammond as to the results of the efforts by the New England governors to meet the deficiency in anthracite by supplying substitutes. Mr. Hammond's observations as chairman of the New England Governor's Coal Committee are of more than sectional interest. He believes communities elsewhere could profit from what has been done in New England and that the task would be easier because they are less exposed to interruptions of fuel supplies.

Mr. Hammond is not disposed to minimize the amount of anthracite production which may be lost. He feels that the country should be prepared for further months of possible suspension. When the strike began Mr. Hammond was inclined to think that the miners and the operators would not be so blind to their own interest as to give their market away to bituminous coal, but now that each seems disposed to fight their battle to the bitter end the public must be prepared, he feels, to use bituminous coal not for a few weeks but throughout the winter.

Mr. Hammond told President Coolidge that the greatest hope of meeting this strike is for the administration to continue its policy of hands off and for the consumer to lay in ample reserves of substitutes. He hopes that New York and New Jersey will follow the example of New England and impress upon the individual citizen that it is his duty under these conditions to place his order for substitutes, rather than hold off buying in the hope that appeals to Washington will accomplish something. Washington cannot mine anthracite.

No great amount of pressure for a political patching up of the strike will come from New England, Mr. Hammond believes. The spirit of the people has been aroused to the point where he believes they are willing to undergo whatever sacrifice is necessary to free themselves from the annual danger of having to go through just what they are enduring this winter. He cites the fact that for every letter received by the Governors' committee complaining of the inconvenience of soft coal nine have come in glorying in the fact that the writer has found a way to use soft coal successfully in his hard-coal equipment. The people have made up their minds, Mr. Hammond believes, to hold the gain they feel they have made thus far and refuse longer to be at the mercy of an industry that can give no adequate assurance as to continuity of supply.

It also is beginning to dawn on the people of New England, Mr. Hammond reports, that bituminous is bound to be the coal of common use in the future. In addition to the realization that continuous supply probably cannot be guaranteed the people are sure that anthracite will become more and more expensive. They are finding even now that they can get the same amount of heat for two-thirds the money.

The people in New England, Mr. Hammond says, have more vision than the dealers. It has been impossible to arouse much enthusiasm among them in the efforts to supply substitutes. Profits are larger in the handling of anthracite and the business is so satisfactory that they hate to see bituminous coal get started, Mr. Hammond told the President. They also have to consider the uncertainty of the situation and are not inclined to put in stocks which might prove unsalable were the strike to end.

Knowing the inborn repugnance of the people of New England to coercion, Mr. Hammond is sure they are through paying tribute, but he fears that they are underestimating the necessity of being as forehanded as possible in providing themselves with substitutes. Some of those who have gone over permanently to the use of soft coal are buying on a hand-to-mouth basis, anticipating a settlement of the strike, when they expect bituminous prices to fall. There is certain to be trouble unless soft-coal requirements are kept moving steadily in maximum volume.

### Producers Have Responsibility

Producers of soft coal and coke have a definite responsibility in this situation, Mr. Hammond asserts. They owe it to the people whose market they want and they owe it to their own stockholders to use every influence to keep prices down. The Governors' committee has been careful to point out that soft coal has been selling at abnormally low prices and that somewhat higher prices than have been prevailing are justified and necessary to a healthy industry. Were prices allowed to get out of hand it would tend to confirm the one-fuel habit.

Mr. Hammond reports that the smokeless producers are preparing to give demonstrations throughout New England in the use of that coal. The coke producers are arranging for the movement of increasing quantities of their product into New England. Plans are being made for the preparation of run-of-mine bituminous at New England points.

Governor Fuller, of Massachusetts, estimates that, in addition to convincing New England that it is not dependent on anthracite, the Governors' committee is responsible for savings to consumers of no less than $4,000,000 to date.

While Mr. Hammond has closed his summer home at Gloucester and has taken up his residence at his winter home in Washington, he expects to make frequent trips to New England this winter so as to keep in close touch with the situation there.

## *Nova Scotia Coal Inquiry Under Way Soon*

The commission appointed by the Nova Scotia government to inquire into conditions in the Nova Scotia coal industry, comprising Sir Andrew Rae Duncan, of London, England, chairman; Dr. H. P. Macpherson, president of St. Francois Xavier University, Antigonish, N.S., and Hume Cronyn, of London, Ont., held their initial sitting at Halifax, Nov. 3. Many officials of the British Empire Steel Corporation, representatives of the provincial government and the United Mine Workers were in attendance.

The first step in the proceedings will be an inspection of several of the collieries and it will be several days before witnesses will be called and the formal inquiry commenced. In the meantime officials of the corporation and the miners' union have been asked to prepare lists of the witnesses they wish called.

## Beware of Mr. Pearson

J. C. Pearson, alias Fidelity Coal & Coke Co., alias Globe Coal & Coke Co., Pittsburgh, Pa.; alias J. D. McCabe Coal & Coke Interests, New York, N. Y.; alias Canadian-American Coal & Lumber Syndicate, Chicago, Ill.; alias Pittsburgh - Cleveland Coal Co., of Cleveland, Ohio; alias J. M. Clarke and A. E. Van Arman, according to a report by the Post Office Department, is under indictment in the U. S. Court, Western District of Pennsylvania, for fraudulent use of the mails in connection with the operations of the Fidelity Coal & Coke Co., together with his partner, G. H. Runstadler, of Detroit, Mich. Runstadler has been arrested, but notwithstanding the fact that the indictment was returned at the May term of U. S. Court in 1923, Pearson has not been arrested.

Under his various aliases Pearson has promoted a number of schemes since he left Pittsburgh. His mode of operation was to establish credit with various coal companies in the states of West Virginia, Kentucky, Pennsylvania and Ohio, and have these operators ship coal to Detroit, Cleveland, New York, or wherever he might desire, and then sell the coal for whatever he could get and appropriate the money to his own use.

With his partner he has obtained over $180,000 from customers in the operation of the Fidelity Coal & Coke Co. and perhaps $50,000 from operations by the Globe Coal & Coke Co. Inspectors at New York say that Pearson realized something like $50,000 while operating in New York, and while he was in Cleveland last January he got in the vicinity of $30,000.

The Post Office Department at Pittsburgh is looking for Pearson, who is said to be about 34 years of age, 5 ft. 11 in. tall, rather stout, now wearing a mustache, an inveterate talker, fond of good living, stops at good hotels and is quite a ladies' man.

## Plans Ready for Meeting of West Virginia Institute

Plans for the meeting of the West Virginia Coal Mining Institute at the Hotel Morgan, Morgantown, on Nov. 24 and 25, are practically completed. One of the features of the opening day will be a paper on "The Smokeless Coal of West Virginia," by D. B. Roger, assistant geologist, West Virginia Geological Survey. Other papers which will be presented will be announced later. A banquet will be held in the evening, with addresses by men of wide experience in the coal mining industry.

The second day will be devoted to inspection trips, including a visit to the Nemacolin mine of the Buckeye Coal Co., one of the largest and best equipped mines in the country.

## Named as Institute Officers

The Nominating Committee of the American Institute of Mining and Metallurgical Engineers has presented the following names which will appear on the official ballots when they are circulated next January. Samuel A. Taylor, consulting coal-mining engineer, Pittsburgh, Pa., as stated in *Coal Age*, Oct. 22, leads the list as president. B. O. Mahaffy, Siberian Oil Co., St. Louis, Mo., and Carl A. Meissner, chairman, coke committee, U. S. Steel Corporation, New York City, are nominated as vice-presidents and directors. The other nominees for director are W. S. Hutchinson, S. W. Mudd, R. H. Sales, H. A. Guess and L. K. Armstrong.

## Founder Societies Will Hold Safety Meet in New York

Plans are complete for a joint safety meeting of the American Institute of Electrical Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Civil Engineers, the American Society of Mechanical Engineers with the American Society of Safety Engineers—Engineering Section of the National Safety Council. This will be held Nov. 18 in the auditorium of the Engineering Societies Building, 25 W. 39th St., New York City.

The subjects treated will be "Economic Aspects of Safety," "Organization and Its Work in Accident Prevention," "Engineering Standards and the Safety Movement," "Prone Pressure Method of Resuscitation" and "Standardization and Safety."

Two other subjects will be "Education in Schools and Colleges in the Solution of the Safety Problem," led by E. A. Holbrook, dean, School of Mines, Pennsylvania State College, State College, Pa., and "Safety in Mines," led by J. V. W. Reynders, president of the A.I.M.E., and discussed by B. F. Tillson, New Jersey Zinc Co., Franklin, N. J.

## Extend Reading Coal Rights

The committee on securities of the New York Stock Echange announces that it has received information that the date of expiration of the right to subscribe of Reading Company stockholders to stock of the Philadelphia & Reading Coal & Iron Corporation has been extended from Dec. 31, 1925, to July 1, 1926.

## N. & W. Fights C. & O. for Coal Business

A battle royal for supremacy in the rich coal fields of southern West Virginia is being waged by the Norfolk & Western and the Chesapeake & Ohio, a unit in the Van Sweringen Nickel Plate system. This became evident when the Guyandotte & Tug River R.R., a subsidiary of the Norfolk & Western, filed a petition on Oct. 31 with the Interstate Commerce Commission for permission to construct a road from Wharncliff, in Mingo County, to Elmore, in Wyoming County, a distance of fifty-three miles.

The petition of the Norfolk & Western was not a surprise in view of the fact that last April the Chesapeake & Ohio asked permission to build a road from Gilbert, in Logan County, the terminal of the present Guyan Valley division, to Mullens, in Wyoming County, and from that point to Stonecoal, in Wayne County, the terminus of the Winding Gulf division. With this extension the Chesapeake & Ohio would be able to bid for some of the tonnage now being handled by the Norfolk & Western, and such an extension would afford a much better eastern outlet.

The Norfolk & Western's proposed extension would tap a rich undeveloped coal area. This road already has a connection with the Virginian at Matoaka, but the proposed extension, it is stated, would provide a more desirable connection. The new road would join the Virginian at Matoaka but westbound shipments of coal could be taken from the Winding Gulf field on the Virginian to Elmore and then be moved from that point to Wharncliff, on the proposed line, where the coal would be turned over to the main line. It is asserted that such a routing would be of material assistance in overcoming transportation problems routing the coal by Matoaka. Operators also believe that by building such an extension the Norfolk & Western hopes to strengthen its case in connection with its application to acquire the Virginian.

That the Norfolk & Western Railway will eventually spend $6,000,000 in and around Williamson, W. Va., is indicated from plans to enlarge the railroad yards at that point to a capacity of 4,000 west-bound loads per day, and by negotiation for the entire property of the Leckie Colliery Co., across the river in Kentucky. The railroad desires the colliery company for the bottom land it controls, desiring to get away from the cramped conditions incidental to bringing coal out of Pond Creek territory, which is causing expensive congestion on the railroad bridge crossing Tug River. The Fordson Coal Co., on Pond Creek, is shipping twice as much tonnage as its predecessors and the Portsmouth Bi-Product Coke Co., at Freeburn, has increased its production. A number of mines in the Thacker field have gone far beyond any tonnages heretofore shipped. It is stated that the Norfolk & Western will be electrified from Williamson to the Tug River field, where electrification west-bound has been stopped.

## Production, Imports, Exports and Home Consumption Of Anthracite and Bituminous Coal, 1913-1924

(In Net Tons)

| Calendar Year | Production | Imports | Exports to Canada and Mexico | Exports to Other Countries (Seaborne) | Net Changes in Stocks[a] | Consumption in the United States[b] |
|---|---|---|---|---|---|---|
| Anthracite: | | | | | | |
| 1913 | 91,525,000 | *c* 2,000 | 4,573,000 | 80,000 | + 1,400,000 | 85,474,000 |

[a] For anthracite the figures are producers' stocks; for bituminous, consumers' stocks. The plus sign denotes coal produced but added to stocks and not consumed, while a minus sign denotes coal consumed that had been withdrawn from stocks carried over from the preceding year. Data on anthracite from cost reports of Federal Trade Commission (Coal, No. 2, p. 27), and hearings before Frelinghuysen Coal Committee, S. Res. 126, 66th Congress, First session (Part I, p. 308). These anthractie figures through 1918 represent coal years, since then calendar years, and are in part estimates. Data on bituminous coal from reports on consumers' stocks of bituminous coal, issued by U. S. Geological Survey, and article, "Is the Coal Shortage Real or Imaginary?" printed in *Coal Age*, Aug. 26, 1920 (p. 429), by C. E. Lesher, formerly coal statistician, U. S. Geological Survey, and director of statistical division, U. S. Fuel Administration.

[b] Production tonnage, plus imports and minus exports, plus or minus the decrease or increase, respectively, of the net change in coal stocks.

[c] Fiscal year ended June 30. [d] No data available. [e] No change.

Data on production, consumption and stocks largely from U. S. Geological Survey reports; import and export figures from records of Bureau of Foreign and Domestic Commerce; issued by U. S. Bureau of Mines

# Monongah Mine to Run Open Shop in West Virginia Union Citadel; Two Companies Sign Baltimore Pact

The United Mine Workers of America received one of the worst setbacks in its industrial struggle in northern West Virginia when the Consolidation Coal Co. announced last week that it would operate mine No. 63, formerly known as No. 8, at Monongah, Marion County, at the 1917 scale. This formerly was the citadel of the union in the district. The Mine Workers retaliated by signing up two companies under the Baltimore agreement in Scotts Run.

Officials of the Consolidation Coal Co. announced during the latter part of last week that more than 60 men were cleaning up the big plant, which had been idle since April. Because of roof falls and other conditions several days would elapse, it was said, before coal was run at the mine. The mine normally employs about 300 men. Incidentally an effort will be made soon to operate the company's extensive beehive coke ovens at Monongah on full time.

Starting Monongah mine is interpreted a decisive step in view of the fact that the largest local union of the United Mine Workers is there. The miners' hall, one of the finest ever erected in any coal region, also is located there. It is the scene of all the union meetings and in it a co-operative motion picture theater is conducted.

Recently the Consolidation Coal Co. reopened O'Donnell mine, No. 57, in Fairmont, located on the Monongahela Ry. at the foot of Palatine Knob, and will be running coal there shortly also.

### Union Signs Two Companies

The two companies which the union announced it had signed under the Baltimore agreement on Nov. 6 are the Tropf Coal Co., which started operation this week, employing 200 men in the Morgantown section of the field, and Satchell Bros., who, it is reported, have leased the By-Product Coal Co. mine in Scotts Run, and will work from 75 to 100 men beginning this week.

According to Patrick Buckley, president of the Monongah local union, "the members of local union No. 1,463 have leased the Hope mine at White Rock and are operating it for the purpose of supplying coal to all those who desire 100 per cent union mined coal." A short time ago the United Mine Workers negotiated for the operation of Josephine mine, in Scotts Run, which was opened on a union basis to furnish coal for members of the union who needed fuel.

The West Virginia Supreme Court of Appeals will hear the motion to dismiss the writ of error granted to Van A. Bittner, chief international representative of the United Mine Workers in northern West Virginia, in Charleston on Dec. 8. Bittner was sentenced for contempt of court by Judge I. Grant Lazelle, of the Monongalia County Circuit Court, in Morgantown, but was granted a writ of error.

It is reported that John S. Forinash, of Grafton, formerly president of Subdistrict No. 3, District No. 17, United Mine Workers, has been selected as commissioner to represent the Consolidation Coal Co. in labor matters. Some weeks ago W. M. Rowan, of Grafton, formerly vice-president of Subdistrict No. 3, was selected by the miners employed by the company to represent them.

Coal mines in the twelve and one-half counties of northern West Virginia produced 600,300 net tons in the week ended Oct. 31, which is the largest since the week ended Sept. 15, 1923. In the first four days of last week the non-union mines produced 6,859 carloads and union mines 1,027 carloads.

A new peak for non-union coal loading in the twelve and one-half counties of northern West Virginia was reached Nov. 6, when 1,883 cars of coal was produced, supplanting the former daily peak of Nov. 5, when 1,810 cars was produced by open shop mines.

---

It is announced that the Southern Pacific R.R. is considering going back to coal for steam on its Salt Lake City division. It was stated that no decision had been made yet regarding the date of the change, much depending on the trend of the oil market and the cost of installing stokers. It is said that the coal chutes will be modernized and that equipment to weigh the coal as it passes from the chute to the tender will be installed.

### *New Hoisting Record Set By New Orient Mine*

A new world's record for coal production was set by the New Orient mine, at West Frankfort, Ill., on Nov. 4, when 11,325 tons was hoisted in an 8-hour shift. This mine formerly held the record with 10,313 tons. The number of miners employed totaled 1,050. The mine, which is known as the world's largest, is three years old and is owned by the Chicago, Wilmington & Franklin Coal Co. It employs the skip type hoist.

### Young Succeeds Bedford

The American Section of the International Chamber of Commerce announces the appointment of Owen D. Young as chairman of the American Committee of the International Chamber, succeeding the late A. C. Bedford. Mr. Young has taken an active part in the affairs of the International Chamber even since it was organized at Paris four years ago. Since then he has served as one of the three American directors. He also served as a member of the Economic Restoration Committee of the Chamber, which recently made a world economic survey with a view to making the Dawes plan more fully effective. The survey was submitted to the meeting of the International Chamber meeting at Brussels last June, and steps are now being taken to put into operation the suggestions made by the committee looking to the stabilization of conditions in Europe.

## *Surveys by National Distribution Conference Point Ways to Eliminate Waste in Business*

Waste in business will be the object of a concerted attack by business men at a general meeting of the National Distribution Conference to be held in Washington, Dec. 15 and 16, under the auspices of the Chamber of Commerce of the United States. The call for the meeting was issued Nov. 8.

More than two hundred manufacturers, wholesale and retail merchants, economists, editors, advertising experts and representatives of trade associations and organizations will weigh the methods by which transactions aggregating upward of $50,000,000,000 annually in the United States, as variously estimated, are carried on. They will attempt to point out the practices which are unethical and economically unsound, constituting major sources of waste, and outline methods by which they may be eliminated.

Six surveys, each covering an important aspect of distribution, have been undertaken by six special committees of representative character. The subjects with which they deal and their chairmen are: "Collection of Business Figures," Owen D. Young; "Trade Relations," A. Lincoln Filene, Boston; "Market Analysis, Advertising and Advertising Mediums," Stanley Resor, president of the J. Walter Thompson Co., New York; "Expenses of Doing Business," Robert R. Ellis, Hessig-Ellis Drug Co., Memphis, Tenn.; "Methods of Distribution," L. D. H. Weld, director of research, Swift & Co., Chicago; "General Conditions Affecting Distribution," G. S. Brown, president, Alpha Portland Cement Co., Easton, Pa.

The wide range of problems brought to light in these surveys will be submitted to the National Distribution Conference with a series of recommendations which will form the basis of discussion and will serve as a definite plan of campaign, national in scope, to be conducted by business for the elimination of waste in distribution.

## Fitzmorris Is New President Of Globe Coal Co.

Charles C. Fitzmorris, secretary to Mayors Carter H. Harrison and Willian Hale Thompson, of Chicago, and chief of police during the later years of Mayor Thompson's régime, was elected president of the Globe Coal Co., Chicago, Oct. 29, succeeding George F. Getz.

Since he resigned as chief of police Mr. Fitzmorris has devoted himself to the coal business, starting April 17, 1923, as president of the Eureka Coal Co., a subsidiary of the Globe Coal Co.

Mr. Getz was elected chairman of the board of directors when stockholders of the company elected Mr. Fitzmorris president. Mr. Getz will leave on a trip to Europe aboard the "Belgenland," Nov. 25.

## Coal and Oil Consumption by Public Utilities Increases

Public utility power plants in the United States consumed 3,423,845 net tons of coal in September, according to a report by the U. S. Geological Survey. This compares with 3,341,464 tons in August, as shown by revised figures. Fuel oil consumption by utilities in September totaled 845,528 barrels, compared with 759,622 barrels in July as shown by revised figures.

The average daily production of electricity by public-utility power plants in September was 179,500,000 kw.-hr., 3½ per cent larger than the average daily output for August.

The total output of electricity by public-utility power plants in the United States from January to September, inclusive, in 1925 was 47,570,000,000 kw.-hr., an increase of 10 per cent over the same period for 1924.

## *Workers' Wages Go Further Than at Peak Period*

A broad and distinct tendency toward rising "real" wages, that is wages measured in terms of what the worker can buy with his earnings, is traced by the National Industrial Conference Board, New York, in a comparative study of representative industries.

Increased application of power, better utilization of labor, mechanical ingenuity and managerial efficiency, according to the Conference Board, are steadily tending to reduce unit cost of production, thereby cheapening the general cost of living, with resulting increasing prosperity for all.

While this tendency is not equally noticeable in all industries the differences in wage levels and cost of production are largely attributable to the different degree of efficiency of production prevailing in the respective industries, the Board points out in comparing conditions in major industrial branches.

The concrete result of this increased industrial efficiency, the Conference Board study declares, is reflected in the fact that while the American workman to day, if we measure the purchasing value of his earnings in terms of the same standard of living as prevailed in 1914 but discount the rise in retail prices, is 24 per cent better off than he was at the beginning of the war (in July 1914), and 5 per cent better off than he was at the peak of wage earnings during the inflation period of 1920.

## Is Pinchot "Giant Power" Plan Fallacious?

The administrative board of the American Engineering Council, meeting at Columbus, Ohio, Oct. 29 and 30, authorized the appointment of a committee to review and analyze the "giant power" report issued by Governor Pinchot of Pennsylvania. The reviewing committee is to be chosen by the executive committee of the Council, to which it is to report at the earliest practicable moment.

The board's action, taken unanimously, followed representations that the "giant power" report contains economic fallacies likely to mislead the public. The aim of the analysis is to provide a popular interpretation of the report from an engineering standpoint.

Plans contemplating a nationwide study of public utilities were set in motion by the board, which voted to appoint a committee to determine a definite scheme of investigation and report to the Council at its annual meeting in Washington early in January.

## Temporary Pay Raise Defers Belgian Coal Strike

The decision of the Belgian national mixed mines committee to grant the coal miners a 5 per cent increase in wages for the month of November postponed the strike scheduled to go into effect Nov. 2. Meanwhile, the mining situation will again be considered.

With the purpose of stimulating the market, the government has decided to purchase 50,000 tons of Belgian coal monthly for the railroads. This fuel heretofore has been furnished from German reparation shipments at an actual loss to the government. The coal stocks at present total 41,644,327 tons.

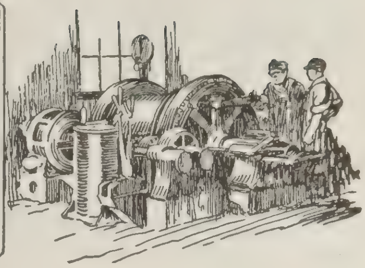
**Chief Winners at International First-Aid and Mine-Rescue Meet**

At the left is the Belleville, Ill., team of the Southern Coal, Coke & Mining Co., which made the highest average in both first-aid and mine-rescue tests at the international meet in Springfield, Ill. Its combined average score was 92.4, which gave it the congressional bronze medallion, the National Safety Council cup and other handsome trophies which are shown here in possession of the winners.

In the photograph are, back row, left to right: James Robertson, superintendent of the mine-rescue station at DuQuoin, Ill.; S. A. Butler, member of the team, but unable to compete because of a broken ankle; James Gatherum, of the American Rolling Mill Co., Zanesville, Ohio, formerly with the Illinois mine-rescue service; W. W. Hunter, superintendent of the Springfield station of the Illinois mine-rescue service. Front row, left to right: Wilbur Beese, "patient," James Dent, Vivian Stuart, Charles Stuart, John Green and David Stuart, captain.

At the right is the American Rolling Mill Co. team of Zanesville, Ohio, which won first place in the first-aid contest with a score of 99.04. This team also took the highest honors among all Ohio teams in its preliminaries. The men in the photograph are, back row left to right: Curt Nagle, captain, James Gatherum, assistant to the supervisor of safety, and Fred McCoy. Front row, left to right: Malcolm Reed, Emmet Lowe, Ralph Frizzle and William Snyder.

# Practical Pointers For Electrical And Mechanical Men



## Home-Made Device Permits Turning Up Tires While on Locomotive

Some time ago, while in the employ of the Davidson Connellsville Coal & Coke Co., it became necessary for me to turn up the tires on a gasoline locomotive. This machine had been in daily service for two years, running on light rails and the tires had become so grooved as to cause trouble. This grooving extended to a depth of about $\frac{1}{2}$ in., being so bad that the machine was knocking the frogs to pieces. It would have been highly inconvenient to send the wheels away to have them turned up and it also would have been quite a job to dismantle the drive gear which is upon the rear axle.

I accordingly got busy and devised the outfit shown in the accompanying illustration with which I removed the false flanges without taking the wheels from under the locomotive. I removed the brake shoes, side rods, rear sand boxes and took out the springs, allowing the journal boxes to go to the top of the frame. Next I removed the oil cellars and made boxings of hard wood lined with half of an old crown brass. The wood box used was of such length that when the pedestal plate was tightened up it held the axle firmly against the regular box without appreciable play. The whole machine was then blocked up from the rails at the ends, so that the wheels were free to turn clear.

The turning rig employed consisted of a steel strap 1 in. thick, 4$\frac{1}{2}$ in. wide and 4$\frac{1}{2}$ ft. long. This was fastened across the frame just ahead of the wheels with two $\frac{5}{8}$ in. U-bolts. A tool carrier was placed on this bar made of the same thickness of iron as the bar itself, the guides being sawed and filed by hand to the proper size and shape. A tool post was next procured and two double-ended turning tools of self tempering steel.

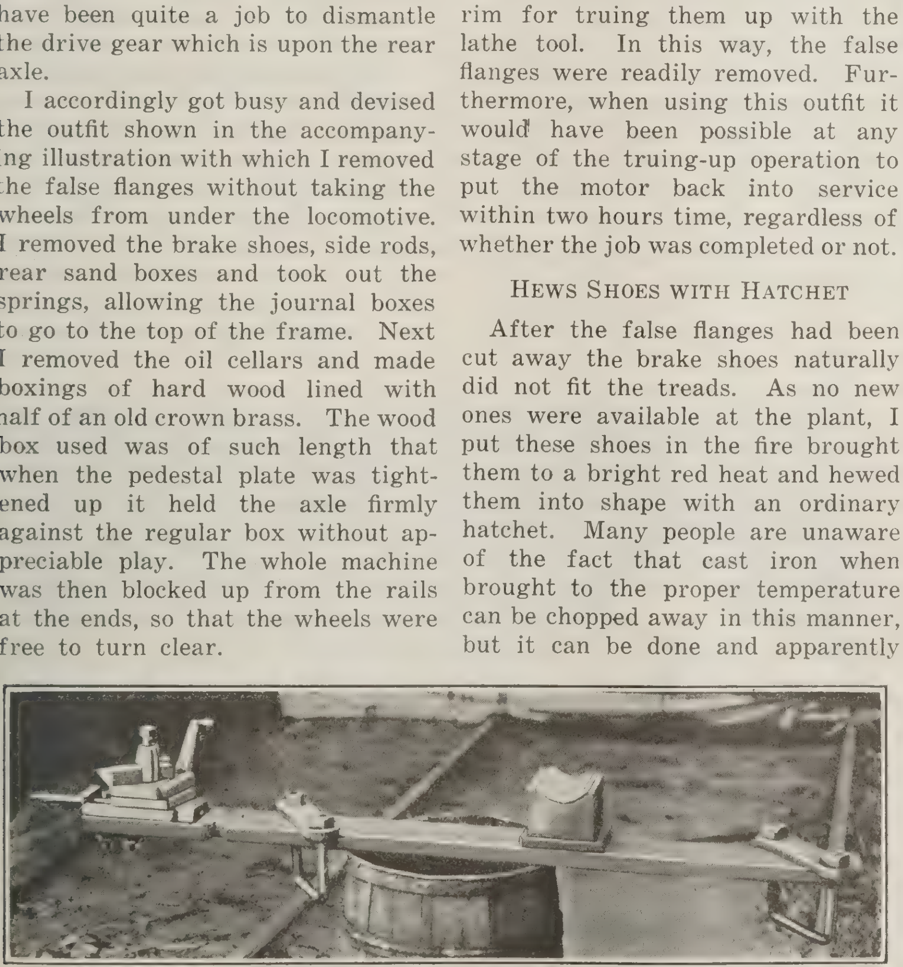
When the motor was started and operated in low gear the drivers had about the proper lineal speed at the rim for truing them up with the lathe tool. In this way, the false flanges were readily removed. Furthermore, when using this outfit it would have been possible at any stage of the truing-up operation to put the motor back into service within two hours time, regardless of whether the job was completed or not.

### Hews Shoes with Hatchet

After the false flanges had been cut away the brake shoes naturally did not fit the treads. As no new ones were available at the plant, I put these shoes in the fire brought them to a bright red heat and hewed them into shape with an ordinary hatchet. Many people are unaware of the fact that cast iron when brought to the proper temperature can be chopped away in this manner, but it can be done and apparently does not injure to any appreciable extent the hatchet used for this purpose.

Charles O'Neil.

Point Marion, Pa.

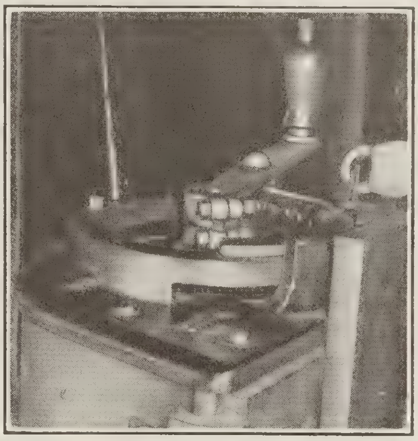


**Simple Equipment for Turning Tire Treads**

With this apparatus the tires may be trued up under the power of the locomotive and without removing the axles from their boxes.

## Padlock Saves Power by Limiting Fan Speed

At a mine where the ventilating fan is equipped with a variable speed motor and control, and where it is not necessary to operate the motor at full speed, it often happens that someone who is not informed as to the proper operating point of the controller, starts the fan and leaves it operating at a speed much faster than necessary. It is not unusual for a superintendent or an engineer, showing a visitor through a mine, to move the controller of the fan back a notch or two and remark: "——— it! Every once in a while I find this fan running faster than necessary."



**Prevents a Power Waste**

A stop locked in position limits the travel of the controller handle and thereby the fan speed. This practically insures operation at the speed designated by the superintendent or engineer.

The fact that at most mines the fan load is practically unvarying 24 hr. a day and, therefore, is responsible for a material portion of the power bill, makes it highly important that the speed be held to a minimum. The accompanying illustration shows how this is done at the mines of the Fordson Coal Co. in Kentucky. A steel segment with a point fitting into a controller notch and locked in the desired position forms a stop for the handle. A fan equipped with this arrangement is never found operating at a higher speed than assigned by the superintendent or engineer.

## Why Did This Motor Heat?

A short time ago a motor in the service of the coal company by which I am employed burned out its bearings. When the armature "poled" the coils became overheated and "shot to ground." This particular machine is of a type that is equipped with waterproof windings that are difficult to repair, the heavy waterproofing requiring removal with a mallet and piece of fiber so sharpened as to form a scraper. The compound was removed, however, and the coils cut out.

In this type of machine the coils are not wound separately but in groups thus obviating stub connections. This, however, increases the difficulty of making repairs. In this case I opened the adjacent coils at the point of diamond or the knuckle and picked up the end that ran to the winding. Of course, this method cuts out some of the turns of a good coil but it is quick and entails less chance of damage through the attempt to find the short stub end near the slot.

The motor was then taken into the mine and connected to the pump that it drives. The mine mechanic reported that it was running very hot, that is, too hot to touch. It was accordingly sent back to the shop and a running test made, the temperature being taken with a thermometer. The motor was operated without load and at the end of 4 hr. registered a temperature of 98 deg. C. As the room temperature was 23 deg. C. the rise amounted to 75 deg. C.

Inasmuch as a class *A* insulation will successfully withstand a difference in room and coil temperature of 90 deg. C. the motor was in no particular danger unless it became appreciably hotter. It was accordingly reconnected to the pump, and after 3 hr. under load registered a temperature of 85 deg. C. The temperature of the mine was 18 deg. C. so that the rise in the temperature of the motor was 67 deg. C.

The question naturally arises why did this motor run hotter without load than when loaded? The reason for this doubtless lies in the fact that the electric shop is at the power plant where the voltage is maintained at approximately 10 per cent above normal to offset line losses and deliver a proper potential at the mine. This motor was wound for 550 volts and operation on a higher potential would probably cause it to heat at the shop more rapidly than within the mine. Eddy currents within the machine are more numerous at high than at low voltages. Their heating effect is consequently greater.

Another reason for the higher temperature attained in the shop as compared to that in the mine was the lower temperature and greater volume of the mine air. In other words, the mine air was in better condition to absorb heat from the motor than was the air in the shop. Then again, the electric conductivity of any metal decreases as its temperature rises so that the conductors of the comparatively cool motor in the mine could carry a bigger current than those of the shop motor.

This action of the motor, as well as that of the mechanic who condemned it, shows the need of having a thermometer available to every man who has charge of motors in any mine. It is impossible to determine with the hand alone whether or not a machine is running too hot. This is because any motor that heats to its allowable 40 or 50 deg. C. rating is too hot to touch comfortably. Furthermore, while the hand is extremely sensitive to even slight differences in temperature it is decidedly inaccurate in locating them on any thermometer scale.

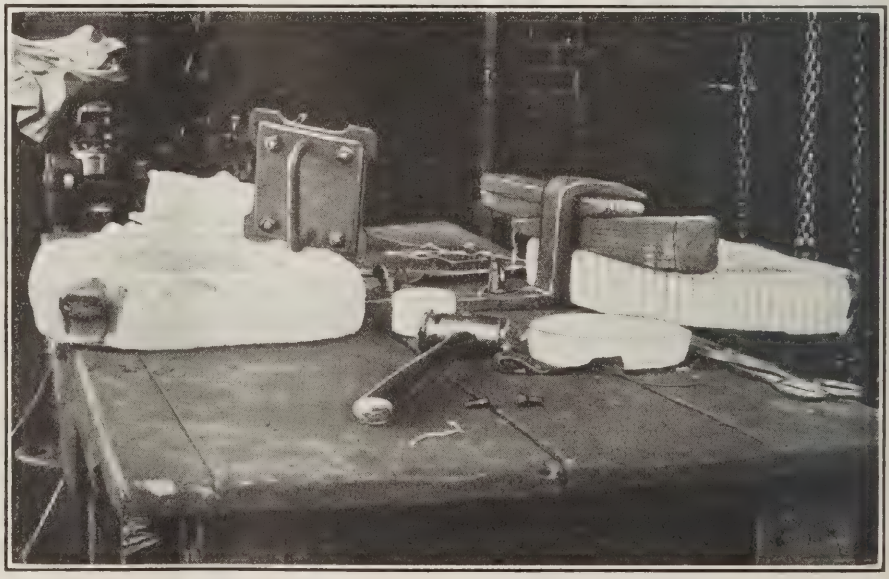
GRADY M. EMERSON,
Alabama Fuel & Iron Co.
Acmar, Ala.

## Clamp and Gage Assist in Retaping Fields

Clearance must necessarily be small between the pole piece and the inside of a field coil, especially on a machine such as a mine locomotive where there is severe vibration and where space is at a premium. Most mine electricians have experienced the trouble of trying to install a field coil in which the hole is just a bit too small to go over the pole piece. This is not an uncommon occurrence with field coils that have been retaped.

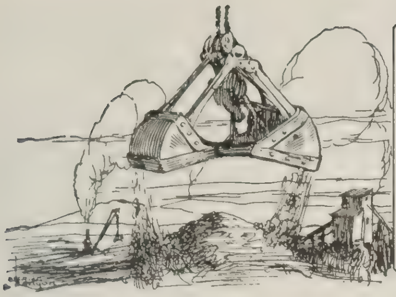
In order to be certain that retaped coils will fit properly in the motor, Bob White, foreman of the winding shop of the Island Creek Coal Co., of Holden, W. Va., uses a gage on each finished coil. This gage consists of a piece of sheet fibre fitted with a metal handle. The corners of the fibre are shaped to correspond with the motor pole piece, but the sides are cut away so that the gage can more easily be tried inside of the coil.

Another device of interest used in retaping field coils is the bench clamp, which can be seen in the accompanying illustration holding a coil in a convenient position. This clamp is nothing more than a Z-shaped iron with slotted holes in the base by which it is fastened with thumb screws to the bench. Two tapered wooden blocks are inserted between the coil and the top of the clamp. While being taped, a heavy field coil is held securely, with any desired overhang beyond the edge of the bench.

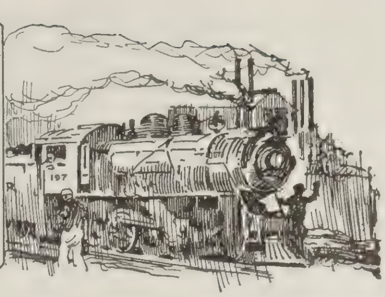


**Test Gage and Bench Clamp Aid Repairman**

Heavy field coils are awkward things to hold while being taped. The photograph shows a coil held in a convenient position, overhanging the bench, by a simple adjustable clamp and two wooden wedges. After the taping is done, the gage, which is lying on the coil at the left, is tried inside to insure proper fitting on the motor pole piece.



# Production And the Market



## Heavy Soft-Coal Output Well Absorbed In Firm Market; Coke Slumps

The growing strength lately in evidence in low-volatile bituminous coal, due to the prolonged suspension of anthracite mining, is now spreading to high-volatile grades. The pick-up continues to be most strongly marked in the prepared sizes, though even mine-run is beginning to improve a little. Screenings also are moving better in Midwest markets and prices have advanced a little. Steam grades are going stronger, full quotas being taken on contracts in most instances.

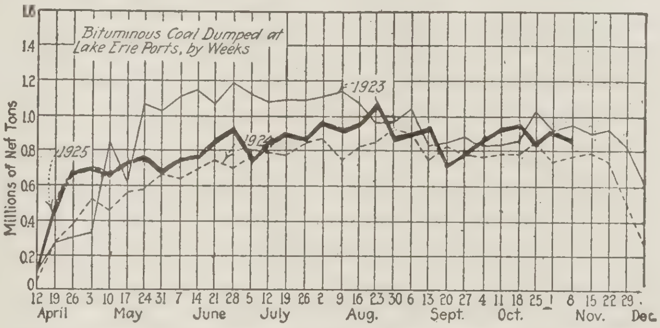
Steady demand for West Virginia smokeless in the East has caused that to be a scarce article in the Middle West, with the result that Illinois, Indiana, eastern and western Kentucky and even Ohio coals are in much more brisk demand and at better prices. In fact, some mines in the eastern Ohio field that have been closed for a year or more are preparing to reopen. Central Pennsylvania coals have been in good demand from Eastern markets and car loadings have been mounting steadily in that field. A sudden slump in demand for egg at Pittsburgh, however, has caused a sharp drop in prices.

New England is an exception in the reports of brisk trade in Atlantic coast markets. Business has been rather colorless with only casual inquiry and prices less firm.

Heavy production, increasing demand and the movement of coal in unaccustomed directions are beginning to bring about a disarrangement of traffic facilities and rolling stock on the railroads that perhaps was inevitable. While car shortages and slower movement are as yet largely local affairs, the likelihood of a spread of such conditions is an eventuality unpleasant to contemplate. Traffic is still heavy through the Cincinnati gateway, 14,975 cars having passed through last week, 2,873 bound for the lakes.

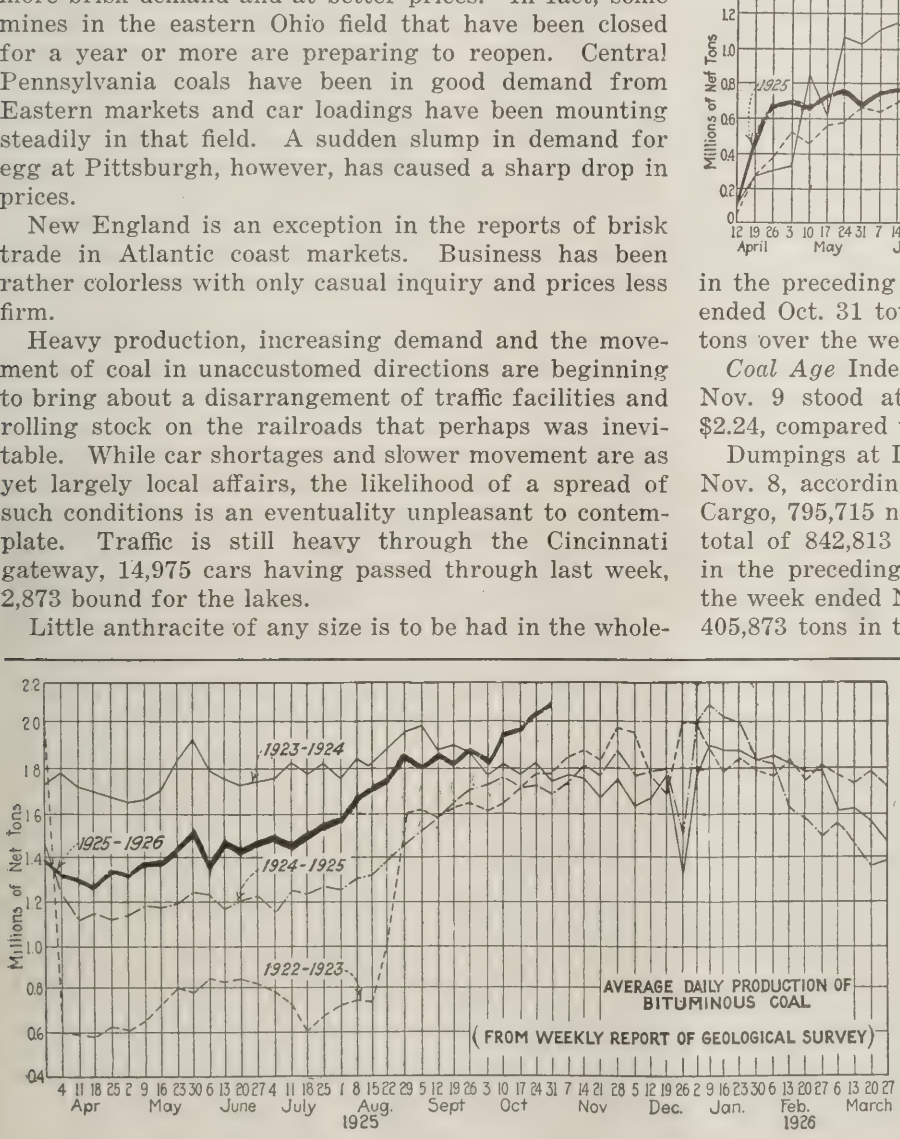
Little anthracite of any size is to be had in the wholesale market. Stocks of pea will soon be exhausted and retail supplies of the larger sizes are dwindling. A sudden let-up in the demand for coke as a hard-coal substitute has brought about a reaction in price, consumers showing a tendency to turn to mine-run soft coal, due to the rapid advance in the prices of prepared coal and coke.

Output of bituminous coal during the week ended Oct. 31 is estimated by the Bureau of Mines at 12,475,000 net tons, the highest weekly output since last January. This compares with 12,088,000 tons produced in the preceding week. Anthracite output in the week ended Oct. 31 totaled 18,000 tons, an increase of 5,000 tons over the week before.



*Coal Age* Index of spot prices of bituminous coal on Nov. 9 stood at 185, the corresponding price being $2.24, compared with 181 and $2.19 on Nov. 2.

Dumpings at Lake Erie ports during the week ended Nov. 8, according to the Ore & Coal Exchange, were: Cargo, 795,715 net tons; steamship fuel, 47,098 tons—a total of 842,813 net tons, compared with 919,425 tons in the preceding week. Hampton Roads dumpings in the week ended Nov. 5 totaled 398,123 net tons, against 405,873 tons in the previous week.



### Estimates of Production

(Net Tons)

| | 1924 | 1925 |
|---|---|---|
| **BITUMINOUS** | | |
| Oct. 17 | 10,599,000 | 11,770,000 |
| Oct. 24 (*a*) | 10,645,000 | 12,088,000 |
| Oct. 31 (*b*) | 10,405,000 | 12,475,000 |
| Daily average | 1,734,000 | 2,079,000 |
| Cal. yr. to date | (*c*) 392,194,000 | 419,368,000 |
| Daily av. to date | 1,525,000 | 1,628,000 |
| **ANTHRACITE** | | |
| Oct. 17 | 1,750,000 | 17,000 |
| Oct. 24 | 1,927,000 | 13,000 |

| Oct. 31 (*b*) | 150,000 | 261,000 |
| Cal. yr. to date | (*c*) 8,083,000 | 8,194,000 |

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Screenings Firmer in Middle West

There have been but few changes in the Midwest coal market during the past week. Illinois operators do not seem to have any trouble in getting sufficient orders for lump coal, but still have considerable difficulty in moving prepared coal in the smaller sizes. The screenings market is bringing much better prices than for several weeks. In the Indiana field the better grades are pretty well sold up, except the smaller prepared coals. No No. 4 Indiana screenings are available. Mines producing No. 5 Indiana coal still have considerable difficulty in moving prepared sizes, whereas there is a brisk demand for screenings, which are rather scarce. Western Kentucky prices have advanced to a new high level. Some companies have raised the price on lump to $2.50, whereas only a month ago it sold at $1.85.

West Virginia and eastern Kentucky prices have been advancing right along with hardly any coal available. Coals from eastern Kentucky and good West Virginia splint are now bringing $3.50 in this territory and west of here, and a number of dealers with little coal in their bins are willing to pay almost any price to get car numbers within forty-eight hours.

The few cars of New River and Pocahontas coal that can be had in Chicago at present are held by jobbers for a premium. Business is rather dull on these coals, except where the dealer is forced to pay the price in order to satisfy some of his trade.

Seasonable weather is evidence of the working time of southern Illinois mines and the movement of lump and egg. Most mines are several weeks behind on lump shipments, egg is about even, but all the nut sizes are slow with the exception of No. 2, which seems to be moving well. This represents the condition at the shaft mines in the Carterville field and also in the Harrisburg field. Mines are getting four and five days a week. Railroad tonnage is running light and car shortage is showing up on nearly all roads. The movement of loads from the mine is not what it should be, everything considered, and indicates serious trouble and delayed movement later when the weather gets bad. Strip mines seem to have a good market for everything and some of them are even crushing the smaller sizes. In the Duquoin field there is some improvement but no railroad tonnage. Prices in all these fields remain unchanged.

In the Mt. Olive district the improvement perhaps is greater than in any other field in the state. Mines are working practically full time and railroad tonnage is good. Domestic tonnage is unusually good with a market that seems to take care of all the steam sizes. There has been an increase in the price of this coal for shipment to the country from $2.75 to $3. St. Louis prices advanced from $2.50 to $2.75 on domestic sizes. In the Standard field there isn't any change in conditions. It is a hand-to-mouth game with a little more working time perhaps this week than heretofore, but prices are about at cost of production and nearly all mines have "no bills" of the smaller sizes

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Nov. 9 | Nov. 2 | Oct. 26 | Nov. 10 |
| Index | 185 | 181 | 178 | 170 |
| Weighted average price | $2.24 | $2.19 | $2.15 | $2.06 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and, second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

on hand which they are unable to move. Railroad tonnage is reported light and buyers usually fix their own prices. Car shortage shows up slightly in this field.

Domestic movement of coal is fairly good to St. Louis, everything seeming to move from Carterville down to Mt. Olive and even Standard—on account of the weather. Apartment house storage is understood to be pretty well in and also school storage. There is an increased demand for coke noticeable locally, but anthracite and smokeless are slow. Public buying is in smaller quantities this year than heretofore. Country demand is fairly good for middle grade coals and the movement of west Kentucky in St. Louis proper is gradually increasing. Country dealers also are taking readily to the west Kentucky product. Country steam is quiet and local carload is fairly active while local wagonload steam is unusually good. Prices are unchanged.

There is a heavy movement of coke from the St. Louis market to as far east as Buffalo, Toronto and intermediate territory. The movement averages seventy-five cars a day from the St. Louis switching limits, some going to Chicago.

### Demand Taxes Kentucky Railroads

Cold weather, along with the Eastern situation and slow deliveries of fuel from the mines, has brought about keener demand and advancing prices in Kentucky. Domestic and steam call are both picking up. Mines are having car troubles in both eastern and western Kentucky. Some of the eastern Kentucky mines report that there is no actual shortage of empties, but that the roads can't move the heavy traffic. Some mines lost two or three days last week on account of traffic conditions.

The general market on best eastern Kentucky block is $3@$3.50 for the bulk of the movement, with better grades at $3.75@$4. Fancy specialty coals are being quoted as high as $4.50 and it is reported that the price is being paid. Lump and egg are around $2.50@$3; nut, $2.50@$2.75; mine-run, $1.50@$1.75, and screenings are higher, at $1.25 @$1.40.

In Western Kentucky 6-in. block is $2@$2.35; lump and egg, $1.90@$2.10; nut, $1.35@$1.50; mine-run, $1.20@$1.50, and screenings, 65c.@90c., the west Kentucky screenings market being lower due to large production and free offerings.

### Activity Unabated in Northwest

No letup is noticeable in shipments from Duluth and Superior docks. Buying by industrial companies has been even stronger during the last ten days, iron mining companies on the Minnesota ranges are buying more steam coal than in some time and retailers have been coming in with re-orders.

Demand for Pocahontas and other smokeless bituminous coals as substitutes for anthracite continue to be an outstanding feature. Dealers have fair supplies of Pocahontas. Its market is persistently stiffening, an advance of 50c. in prepared sizes having been announced this week, making the figure $9. Mine-run and screenings are unchanged at $5.50 and $4.25 respectively. While supplies of Pocahontas screenings are accumulating on the docks, the trade is generally sanguine that they will all be needed for special purposes before the season ends.

Anthracite on the docks will be practically exhausted within two months. An advance of 15c. on nut and 50c. on pea was announced this week, making the line-up as follows on docks: Egg, $13.20; stove, $13.60; nut, $13.60; pea, $11.50, and buckwheat, $6.50. Pea and buckwheat have both been in demand lately to mix with coke as an anthracite substitute. Domestic coke is unchanged at $8.50 and briquets are unchanged at $9.

Thirty cargoes via the lakes were unloaded at the docks and seventeen cargoes were reported en route. Bituminous stocks on the docks here total 3,400,000 tons, of which around 2,000,000 belong to the railroads.

Milwaukee dock managers report hard coal virtually out of the market and the better grades of soft coal looking up because of the enormous demand upon the mines. Consumers who can use soft coal are calling for that fuel, and those who cannot burn soft coal are turning to coke. The better grades of bituminous coal have advanced $1.50 in Milwaukee, with a prospect of still higher figures. The little anthracite in some hands is retailing at $18.55 for stove, $18 for chestnut, $16 for pea and $11.75 for buckwheat, with 75c. deducted when fuel is not carried to the bins. Pocahontas egg and lump sell for $14.50, range size for $9.50 and mine-run for $8, with 75c. added for carrying to bins. No hard coal has been received by cargo in Milwaukee since Sept. 15. The receipts for the season up to Nov. 6 total 3,161,701 tons—488,234 tons of anthracite and 2,673,467 tons of bituminous coal.

### Orders Keep Southwest Operators Hustling

While the Southwestern market this year is immediately responsive to changes in temperature, orders have piled up in such quantity during recent cold snaps that mines would be assured of full working time for at least two weeks if the demand should cease entirely. Operators are, for the most part, two weeks behind with deliveries of Kansas lump and from two days to a week on nut. Even screenings have been affected by the brisk demand. All surpluses have been cleaned up in the field and some operators are two or three days short. The result of the general activity has been more firmly to establish the price of $5 for Kansas shaft lump and to steady screenings quotations around $2.35, although some are to be had at $2.25. Kansas shovel lump is bringing $4.50@$4.75, with quotations for other shovel grades the same as those for shaft.

In Colorado there has been a splendid demand for domestic lump and nut and steam sizes of coal for the past week, the mines working full time and some of them on double shift. Some operators are booked up for the entire month of November. All mines are operating without any interruption by transportation and labor.

As a result of the increased demands prices were advanced 50c. per ton Nov. 1. Walsenburg-Canon City lump coal is $6; washed nut, $5; washed chestnut, $3; Trinidad 6-in. coking coal for domestic and steam uses, $4.25; 3-in., $4; nut, $3.50; Crested Butte high-grade anthracite Nos. 1 and 2 (furnace size), $7.25; Nos. 3 and 5 (baseburner size),

$7.75; Horace Nos. 1 and 2 (furnace size), $9; Nos. 3 and 5 (baseburner size), $9.

Working time in the Utah coal fields is improving as a result of the first signs of winter. Dealers report rush orders. The demand for coal for heating purposes is on a serious scale for the first time this season. There is plenty of coal in dealers' yards and the car situation is generally good, so there is not likely to be a coal shortage, regardless of the weather. Demand for slack is much better again. Nut and stove are moving less freely than other sizes, but no size could be said to be a drug on the market at this time. The demand for Utah coal outside of the state is said to be about normal for the season. The price situation is unchanged and there is an abundance of labor.

### Trade Generally Firm at Cincinnati

Car shortage in an aggravated form and a flood of buying orders did the expected to the high-volatile market at Cincinnati this week. The basis on block, 4-in. and 6-in. lump rose to $3.25 with the market closing strong. Taking two to three days a week in production away from the southeastern Kentucky market seems to have been the thing that started prices to run away. Cold weather also must be reckoned in.

Egg and 2-in kept pace, with $2.75 as the low and $3 asked for the better grades. Some specialized coals from the Elkhorn and Hazard districts went as high as $3.25@$3.50. Mine-run was a little slow in getting started, but by Saturday $2 asked was not infrequently heard for the better types, especially gas coals and malleables. Some stuff still could be had around $1.50@$1.65 for steam purposes, but this was getting scarce and was eagerly picked up. Screenings and slack were sought with the rise and sales at $1.40@$1.50 were reported, though the general spread was closer to $1.25@$1.50.

Movement to the lakes continues heavy, though the end of the season is approaching; 2,873 cars moved lakeward last week, a decrease of 251 cars. In all, 14,975 cars passed through the Cincinnati gateway.

In the smokeless market an effort is being made to get prices in better alignment. Inland dealers are raising a rumpus and it has been difficult to get them interested in $6 coal. They'd rather take high volatiles. Trading on a $5 basis is much better. The East is still taking $6 egg and nut, but sales are slackening some. In fact some companies made their price $5.50@$6 for later deliveries rather than touch any of the spot business at the top. Mine-run stiffened some, $2.50@$2.60 being the price named. Screenings were solid at $2.

Columbus is slowly digesting the price advances of Nov. 1 and consequently buying is not quite so active, although the market continues firm as to domestic sizes. Retail prices have been advanced in sympathy with higher prices at the mines. Some car shortage is reported. There is practically no free coal on the market as far as domestic sizes is concerned and thus no cheap cargoes to be picked up.

Steam business is still rather spotty and quiet. Buying by large users is for current needs mostly, although some show a tendency to stock up. Screenings are slightly weaker, owing to a larger production of lump and prepared grades. Considerable mine-run is now going into the lake trade and that has been one of the best features.

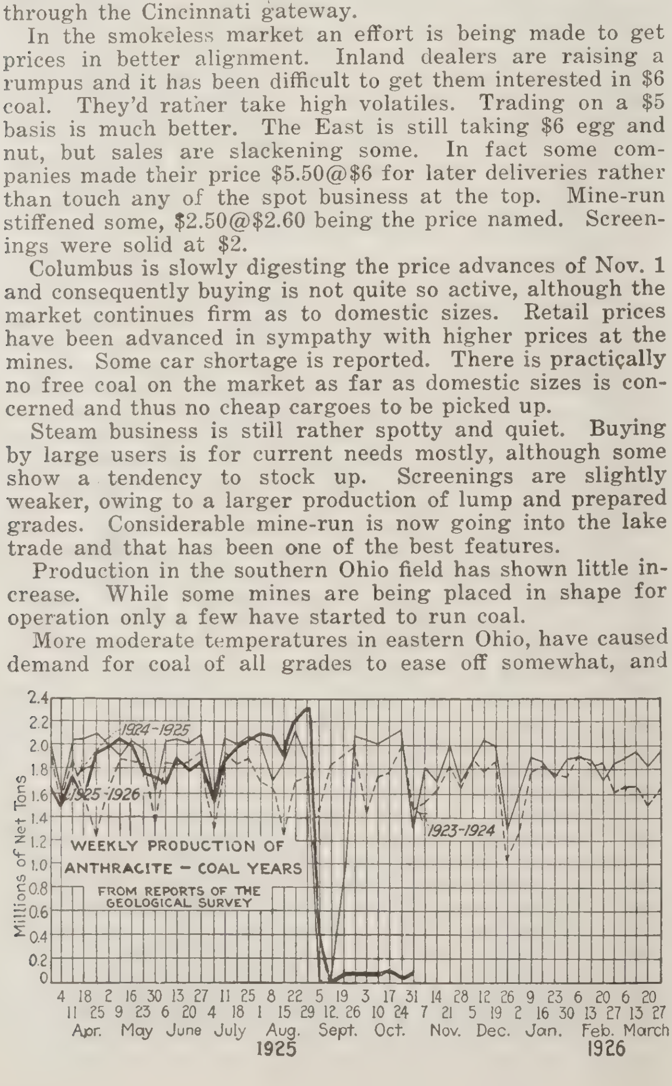
Production in the southern Ohio field has shown little increase. While some mines are being placed in shape for operation only a few have started to run coal.

More moderate temperatures in eastern Ohio, have caused demand for coal of all grades to ease off somewhat, and spot prices are softer by 5c. to 10c. per ton compared with a week ago.

With immediate needs of domestic consumers at least temporarily taken care of, retail orders at the mines are not so strong. However, local quotations on Pocahontas lump are still $6 per ton f.o.b. mines, due to the unusually heavy demand in the East. West Virginia and eastern Kentucky domestic lump is quoted at $3.25@$3.50 per ton, f.o.b. mines. As retailers have been unable to get quick deliveries on Southern grades, Ohio mines preparing coal for domestic use have had a heavier demand of late.

Steam orders are mostly for small lots as compared with previous seasons, as the larger consumers are not at all apprehensive as to their ability to continue to get coal as needed. The railroads have been taking full commitments on contracts and shipments to the lakes trade has been unusually heavy for the late season. The market is readily absorbing most of the coal offered.

Production in the eastern Ohio field during the week ended Oct. 24 was the largest of any week of the year—313,000 tons, or about 45 per cent of capacity. During the week ended Oct. 31 output was 309,000 tons, the second largest thus far this year.



### Eastern Demand Relaxes at Pittsburgh

While there is a fair run of industrial and railroad buying of coal and heavier buying of domestic coal in tributary territory the feature of the Pittsburgh district coal market for a while was the demand from the East. The Eastern call for egg suddenly slumped, however, and as sellers have lately been reserved, on account of advancing prices, there were promptly heavy offerings and the price broke sharply. It is now impossible to obtain more than $3.25 from Eastern buyers for shaker screen egg coal, the best prepared of all. The market had been $4.50@$5 and $5.25 was obtained on a few sales. The reaction is attributed to heavier offerings of West Virginia smokeless. Slack is weak but has not receded beyond the decline of a week ago.

The bituminous trade proper at Buffalo is as dull as ever. The regular trade does not want slack and it is more or less indifferent to anything else. Prices cannot be said to have gone off, for they probably will hold till the substitute fuel is out of the market, but there is enough smokeless and screened lump going into cellars to create an interest in the entire trade, especially as prices are a dollar or two up.

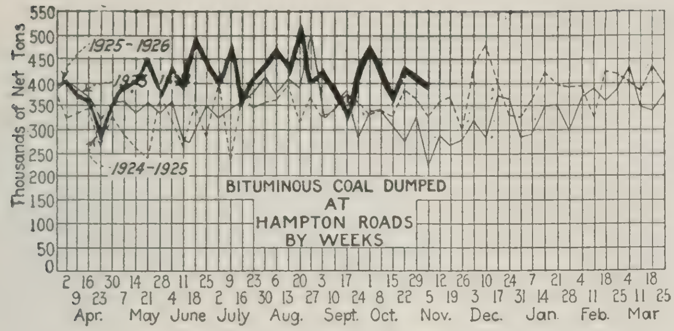
### New England Market Lacks Color

A colorless market has ruled in New England in the past week. For mine-run steam coal there has been only casual inquiry, and prices are now hardly as firm as when last reported. Larger accumulations are in evidence both at Hampton Roads piers and on rehandling wharves at this end. There is so much complaint of slack in cargoes that come forward that retail dealers have little comfort in relying on any considerable proportion of lumps to offer as substitutes for anthracite. As between Welsh anthracite, coke and screened bituminous dealers are feeling their way and making purchases of pea and buckwheat wherever possible.

High-grade smokeless coals f.o.b. vessels at Newport News and Norfolk are held at prices seesawing around $4.90@$5, with only light tonnages being placed on the spot market. Slack is again a drug on the market, and new low figures have been made quietly to move accumulations. The lucrative prices now being realized for lump, egg and nut have tended to increase the available supply of slack.

Quotations on cars Boston and Providence are within easy range of $6 per gross ton. Spasmodic efforts have been made to advance the figure to $6.50, but conditions now do not warrant any such level. At retail in Boston the delivered price of steam coal is now $8, while $12 is being asked for lump for domestic use.

The Pocahontas and New River interests are active in trying to place prepared sizes in this market, although for the present, owing to rate differentials, they are restricting their efforts to areas reached by the N. Y., N. H. & H. On Nov. 6 the smokeless operators held a conference in Boston with representatives of the New England Governors' committee and set on foot plans for systematic merchandising of screened bituminous. The trade itself, however, which in all these negotiations has been very little con-



sulted, continues to show a marked preference for Welsh anthracite, English ovoids and even Scotch coke. And even of these substitutes the dealers thus far have bought only sparingly.

All-rail from Pennsylvania there is any quantity of good coal that can be bought at $2.25@$2.50 per net ton, f.o.b. mines, but continuing low prices on Pocahontas and New River from tidewater points give the latter the preference.

## New York Trade Firm but Not Spectacular

Bituminous prices at New York are fairly steady, advancing only in spots. Failure to show a more buoyant tone is not due to lack of buying, which is brisk, but to the fact that supply has fully kept pace with requirements except for special grades of coal.

Domestic screened coal is holding firm at the prices prevailing for the past few weeks. The point seems to have been reached where buyers prefer mine-run rather than bid higher for the limited amount of prepared coal that is available.

Central Pennsylvania operators who are equipped to ship egg and stove sizes are selling them for $6.50@$8 a ton, the Broad Top coals commanding the maximum figure. Screened lump is bringing $4.50@$5.50. High-volatile egg and stove sizes command around $4.50@$5, with some producers quoting as high as $5.50.

There has been a decided improvement in the Philadelphia market, the improved demand for coal being due to the anthracite suspension. As yet the usual consumer of soft coal, however, seems a bit indifferent. Customers with contracts are taking their regular allotments. Prices generally have moved upward and probably will continue to do so, as the demand for coal from the former anthracite market shows no signs of abatement.

The soft-coal market at Baltimore is a rather mixed affair. Industrial demand is no more brisk than it has been for several weeks past and the price of run-of-mine coals continue on the same basis that has applied for at least three weeks. Prepared sizes, however, are in active demand at $5.50@$7.50 per ton as a result of the hard coal strike. There has been a pronounced slump in the export coal trade from Baltimore.

Cool, crisp weather is having a favorable effect on the domestic trade at Birmingham. Orders are coming in to retailers in sufficient numbers to keep them fairly busy, and more liberal shipments are being taken on contracts by dealers. Spot demand is good and the volume of business being booked is sufficient, with contract commitments, to move current output without any worth-while delay. Demand for the better grades is the more pronounced, and most of the business placed is for immediate shipment.

The market for commercial coal is very active and the demand for the better grades is sometimes in excess of the supply immediately available, and this condition is serving to lend more strength to the demand for medium and lower qualities. Reports indicate, however, that fuel users are not yet giving consideration to stocking. Movement of bunker coal during the past week or so has been much heavier than for some time past.

Quotations on steam and domestic fuel are stable, with an inclination toward higher levels for the better qualities of washed and mine-run product.

The coke market continues brisk with quotations $6@$6.50 for spot foundry grades, $4.25 and $4.50 for nut and egg sizes, respectively, and $4.25@$4.50 for gas coke.

Complaints of car shortage have been heard throughout the district, but the situation has not assumed a serious aspect as yet.

## Anthracite Users Less Keen on Substitutes

At New York the supply for some kinds of anthracite substitutes has caught up with the demand, at least for the present. This is particularly true of coke, where a slight price reaction has taken place. Screened bituminous is holding its own, but is no longer advancing. Buying seems to be turning more to mine-run, owing to coke and prepared coals having gone up too rapidly.

Most retail dealers have made initial purchases of one of these fuels, and because of fairly good sales have in many instances sent in repeat orders. This has occurred more in the metropolitan area than in the small towns, where substitutes do not sell as readily because most house owners have their winter fuel in their cellars and retail stocks of hard coals have been sufficient to take care of the hand-to-mouth buyers.

If the anthracite strike lasts much longer the public will have to take to substitutes to a greater extent, but just now there is a general tendency not to buy anything in that line until it is absolutely necessary.

No company coal of any size can be obtained by the average buyer. The companies still have some buckwheat in their stocking plants, but it is believed to be covered by contracts and orders. Speculative buckwheat is offered in New York harbor at $8 to $8.50 alongside, and a few cargoes of pea are said to be available at around $17.

The Philadelphia market is fast reaching the point where little anthracite of any size is to be had. A few company shippers continue to ship lightly of pea coal, but the report is that all stocks will surely be exhausted by Dec. 1. Retail yards are almost cleaned out of large sizes, a few retaining a small tonnage to meet special cases. Stocks of buckwheat held by the company producers are diminishing rapidly, all companies having reached the point where they are no longer open for additional orders for this size.

Dealers, having decided that there will not be enough coke or sized bituminous coal to go around for hard-coal substitutes, are ordering low-volatile bituminous.

There is practically no hard-coal situation in Baltimore other than a scarcity of anthracite in yards. Outside of a few having limited supplies, which they are releasing in one and two ton lots to customers they consider in the most need, dealers are advising customers to seek substitutes for hard coal.

At Buffalo the small sizes of anthracite are running short. Pea has about given out and buckwheat is anything but plentiful. Probably the member of the trade who makes the most money in the trade is the coke producer. All the available ovens are active and new ones are being got ready as fast as possible. The curb price of furnace coke is now about $15 a ton and some dealers are asking more.

## Slump Hits Connellsville Coke Market

Continued light demand from the East for Connellsville coke, both run of oven and broken, came suddenly to a climax with a fall in prices. Sales were made Saturday at $6.50@$7 for run of oven. Some say broken is hardly any better, others say $8@$9 is obtainable. The main influence seems to be congestion in the East, with several railroad embargoes on both coal and coke, there being 1,400 cars of coke at Perth Amboy and 1,000 at the Reading pier, as well as much coal.

Sudden changes are likely, from the character of the market. With a lull in buying coke soon started to accumulate. The operators can expect no storage favors from the railroads, particularly when loaded cars are blocked in the East, as demurrage charges would be clapped on instantly, so the coke has to be sold.

Foundry coke has not actually made a new market since the slump in furnace coke, but may be appraised at $8@$8.50.

# Foreign Market And Export News

## British Coal Market Advances Gradually; Inquiry Developing

In the South Wales steam coal trade conditions do not show much further progress. Shipments are expanding, but lack of ready steamers has contributed to limit activity. Dry steam coals have improved to some extent by taking the surplus business that would normally have gone to the anthracite market. This is particularly the case in regard to sized coals of the dry class, which constitute an excellent substitute for anthracite for stove purposes.

New business in ordinary steam coals, especially in the case of Monmouthshires, has been developing slowly. Work in the district has been exceedingly irregular, and it has been decided to serve notices on the men employed at several additional collieries.

Improvement continues at Newcastle-on-Tyne, where the coal market position is strong. There have been heavy bookings of all classes of coal for shipment and supplies are now getting scarce, only comparatively small lots being obtainable. Inquiry for next month also is good, but the tendency for the moment is to hold off in view of the long loading turns. Inquiries are circulating, too, for delivery to the end of the year and to March, but though merchants are offering to sell freely ahead they are not disposed to discount present prices and forward transactions are understood to have been closed on these terms. A strong tone has developed in the coke trade. Gas coke is firm and higher.

Production by British collieries during the week ended Oct. 24, according to a special cable to *Coal Age*, totaled 4,820,000 gross tons, compared with 4,715,000 tons in the preceding week.

## Gains Counterbalance Losses At Hampton Roads

Activity at Hampton Roads last week was without feature, the market apparently holding its own, with increases in business in some angles offsetting slight depressions in others. Foreign business appeared to be holding its own, but coastwise trade was barely up to normal.

Domestic business was on the increase with the advent of cold weather and bunker trade was at a normal level. The tone of the market was fairly strong and the situation was described as steady. The production of coal in some southwest Virginia mines was reported as on the increase, in anticipation of better winter business.

At the request of a small group of coal shippers, who assert that information being released by the coal piers has given their competitors in this port, as well as coal shippers in other ports, too great an "inside track" on the coal market here, the piers have discontinued issuing the regular reports on the coal situation.

## French Industrial Coal Demand Equal to Supply

In the French coal market supply and demand for industrial coals are more or less equal, which, on the whole, is rather satisfactory. This is explained in part by increased activity in the metallurgical, textile and glass industries and by the protection given to French coals by the rise in sterling.

In domestic coals, merchants are grumbling about the delay in shipments—as much by French and Belgian producers as by British anthracite exporters. Considering the heavy weather, the demand has been rather weak during October.

Two additional shiploads of Russian anthracite are on their way to Rouen.

Receipts of indemnity fuels from the Ruhr during the first ten days of October included 110,200 tons of coal, 77,800 tons of coke and 9,400 of lignite briquets. These figures do not include free contracts imputed to the reparations account.

During the first twenty days of October the O. R. C. A. received from the Ruhr 145,571 tons of coke. The German government consented to a reduction of 1.50 m. in the official price of coke, which made the price 22.50 m. beginning Oct. 15.

Exports of French fuels in September included 480,144 metric tons of coal, 51,610 tons of coke and 10,690 tons of patent fuels, the totals for the first nine months of 1925 being, respectively, 3,265,955 metric tons of coal, 321,142 tons of coke and 92,411 tons of patent fuels. Imports in September were 1,636,322 metric tons of coal, 420,394 tons of coke and 147,994 tons of patent fuels, the respective totals for the first nine months of 1925 being 13,207,148 metric tons of coal, 3,827,584 tons of coke and 925,609 tons of patent fuels.

# News Items From Field and Trade

## ALABAMA

The stockholders of the DeBardeleben Coal Corporation have approved a new financing plan adopted by the board of directors of the corporation providing for the issuance of $1,500,000 in bonds, which it is understood is to provide for refinancing and also betterments and improvements to be made in the future. The corporation is now enjoying a splendid business, all of its large and well-equipped mines operating on a full-time basis. Henry T. DeBardeleben is president of the company. The general offices are at Birmingham.

Joseph A. Norman has withdrawn from the firm of Adams, Rowe & Norman, wholesale coal and coke sales agency, with which he has been associated since its organization in 1919. Mr. Norman is well known in the trade, having been connected with the operating firm of Bonnyman-Norman Coal Co. for a number of years prior to the organization of the firm from which he is now withdrawing and is thoroughly acquainted with both the selling and operating phases of the industry. Mr. Norman has not announced his plans for the future.

The St. Louis & San Francisco R.R. has placed an order with the Fairfield car shops of the Tennessee Coal, Iron & Railroad Co. for 500 gondola cars, which are to be delivered during the early part of next year. The Frisco is one of the largest coal-carrying lines in the district and mines on its lines are now operating practically full time.

A number of idle Alabama mines are preparing to resume operation at an early date. The Alabama By-Products Corporation has reopened its No. 15 drift opening, near Dora, and it is understood that the Sloss-Sheffield Steel & Iron Co. is cleaning up its Ivy mine, which has been idle for about three months, and will resume mining there as early as practicable. The new Crockard Mine No. 5, being developed on a large scale by the Woodward Iron Co., is expected to begin production in a small way during the first quarter of 1926. This is a shaft opening and will provide facilities for the removal of several hundred thousand tons of Pratt coal in a virgin field.

The Alabama By-Products Corporation is modernizing its mines at Flat Creek and Praco, these operations being electrified and mining machines being installed at the latter point. Wegra mines also have been electrified fully and a new electric hoist has been installed at this operation recently. It also is understood that a large coal bin will be constructed there. A new washery has been built at Blossburg and also one at Mineral Springs.

## ARKANSAS

With 28 men in its employ the New Coronado Coal Co., the only coal mining concern operating at Huntington, is running full time six days a week. The 1924 scale of wages is being paid. The management expects to continue operations throughout the winter.

H. D. Covius, M. H. Covius and Sturius Covius, all from La Salle, Ind., and V. Rube and E. T. Barnes have been inspecting the Dixie Girl Mine, which is situated between Buffalo and Rush, with a view to buying it.

## COLORADO

A shortage of approximately three hundred miners exists in the Fremont, Las Animas and Huerfano County coal fields, according to an estimate by E. H. Weitzel, general manager of the Colorado Fuel & Iron Co., at Pueblo. Unofficial report is to the effect that a similar condition exists at the mines of the Victor-American company. Diversion of labor to the beet fields and the sugar factories is believed by officials to be largely responsible.

The statement of the Colorado Fuel & Iron Co. for the quarter ended Sept. 30 shows gross receipts of $6,141,769, compared with $7,492,540 in the corresponding quarter of 1924. Operating expenses of $5,442,089, compared with $6,840,267 in the 1924 quarter. Income above fixed charges was $70,847, against $17,413 the year before, which left a deficit of $186,334, against $239,768 after $257,181 had been deducted for depreciation.

## ILLINOIS

The Jeffery mine, Herrin, operated by Pratt Brothers, established a new hoisting record Oct. 12, when 2,966 tons of coal was hoisted in eight hours without any prior preparations or accumulations of coal to speed up the day's work. The mine hoisted 1,085 pit cars. One year ago the Jeffery mine set a record of 2,866 tons in eight hours by hoisting 1,055 pit cars.

Secretary James Mason of the Belleville subdistrict of the Illinois United Mine Workers has received a check for $6,067.28 from Receiver J. Kapp of Chicago, who was named by the federal court in St. Louis as receiver of the Missouri-Illinois Coal Co. and People's Coal Co., both of which went into bankruptcy in September, 1923. The check is for wages of 194 miners employed by the mining companies.

Rice Miller, Hillsboro, has been elected president of the Illinois Coal Operators Association.

Mine No. 7 of the Consolidated Coal Co., at Herrin, resumed full time operations late in October. This mine had been running at half capacity for several months.

Charles L. Dering, of Chicago, formerly president of the American Wholesale Coal Association, was made an honorary member of the Chicago Association of Commerce by unanimous recommendation of the executive committee at a meeting of the board of directors on Oct. 15. He retired from active business during the past year.

The Weaver mine of the Old Ben Coal Corporation, near Herrin, has resumed operation. Five hundred men had been idle since it closed down in February.

## KANSAS

The question of moving headquarters of District 14, United Mine Workers, from Pittsburgh will be submitted by referendum to the locals of the district some time in November. Arma has volunteered to boost its offer of $10,000 toward the erection of a building for the district offices to $15,000, and already is said to have received pledges of more than $9,000 of the amount. Frontenac's offer is to remodel an existing building there and permit the district officers to occupy it without rent.

Drill tests near Cherokee to locate a vein of coal adapted to shovel operation are being made. Two or three shovels are expected to be employed in the development of the vein when its bounds are determined. The vein is from 18 to 26 in. thick and is from 16 to 22 ft. from the surface. The Western Coal & Mining Co. is among those interested in the tests.

Employees of the Home Riverside Mining Co., who have been idle since May, were notified last week that unless a new wage agreement is reached within sixty days the mine would be closed permanently and the property abandoned. The company employees have been receiving a wage of $7.50 a day. The company wishes to reduce this to $5, declaring the mine product cannot be sold in competition with other coals if the higher rate is paid. Should the mine not be reopened, such action will mark the end of the coal industry in Leavenworth, where at one time four mines were in operation employing twelve hundred miners.

## KENTUCKY

The O'Neal brothers, (J. T. and Emmett O'Neal), interested in the Emmett O'Neal Coal Co., Louisville, were much in the limelight over the past few days. Judge J. T. O'Neal with forty-eight hours' notice stepped in and ran on the Democratic ticket for Mayor of Louisville, when W. T. Baker, the regular candidate stepped out of the picture, having withdrawn when publicity was given to his former connection with the Ku Klux Klan. His brother Emmett O'Neal was running for sheriff on the same ticket. In spite of the sudden change in candidates, the O'Neal brothers were defeated by less than 3,000 votes, and by a machine which has been in control of local politics for ten years or more. The boys are quite popular, former athletes, and well connected socially. They made a much better race than had been generally predicted.

The Old Hickory Mining Co. expects to rebuild its old mine at Hite installing new mine cars, fans, electric substations, and electric machinery.

Parker & Tillinghurst, Cincinnati engineers, are reported to be drawing plans for the construction of a $100,000 plant for the Process Fuel Co. at Sixth and Davis Sts., Louisville. Emmett O'Neal Coal Co., Emmett O'Neal, Robert C. Logan, W. O. Alben, O. Marting, Dayton, Ohio, John G. Hettinger, of the Kentucky Fluorspar Co., and W. G. Eaton, of Cincinnati, are interested in the concern.

The Kentucky Public Utilities Co., Louisville, one of the Insull Companies, through vice-president L. B. Herrington, has announced the purchase of the Paducah Electric Co., including light and power, street railway and water gas plant holdings. The Kentucky company controls many miles of high-tension transmission lines in both eastern and western Kentucky, supplies current to many towns and coal plants. It recently purchased the 5,000-hp. power plant of the W. G. Duncan Coal Co., at Greenville, which it had previously had under lease, and also has the St. Bernard Mining Co.'s 5,000-hp. steam plant under lease.

Patrick E. Crowley, of New York, president of the New York Central Lines, and a group of company officials paid a visit to Louisville last week in connection with plans for the construction of a new Ohio River bridge at Louisville. The present bridge, completed in 1893, is too light to handle heavy coal trains and big engines, causing some traffic that should go through Louisville to be routed through Cincinnati.

It is reported that the Carr's Fork Coal Co., at Carr's Fork, in eastern Kentucky is planning to increase production capacity to forty cars from twenty-five. A new store building, sixty new miners' homes, additional mine openings, enlargement of the tipple, and other improvements are planned. It also is reported that the Hardy Burlingham Mining Co., in the Hazard field, is installing equipment for larger production, and is completing 100 new miners' homes.

**A Dispensary at a Southern Mine**

This particular dispensary is located at the Edgewater Mine of the Tennessee Coal, Iron & R.R. Co., in Alabama. Like most of the other mine buildings at this plant it is of neat brick construction. More and more, as time goes on, employers are coming to realize that it is good business to care well for the physical needs of their employees.

The holdings of the New Bell Jellico Coal Co. were sold at the Pineville Court House door Nov. 2 for $35,800. The total indebtedness of the company will reach about $339,000 and in addition to this there was sold about $350,000 worth of capital stock in the concern. The property was bought at the sale by R. E. Adams, Louisville, Miss Golden Day, Natural Bridge, and J. H. Adams, of Louisville, who held a mortgage on the property. The New Bell Jellico Coal Co. was organized about fifteen years ago. W. Mac Johnson, formerly of Lexington, but now reported a resident of Florida, operated the mine until it was placed in the hands of receivers a short time ago.

E. W. and Bert Dozier, of Madisonville, have bought 752 acres of coal rights near Madisonville at a reported price of $190,000 and will develop it with five slope mines. Development is to begin at once. The mines will be on the Madisonville line of the Illinois Central R.R. Daily output of each mine will be from ten to twenty cars daily. Following the deal the Dozier brothers announced that they had formed the Kentucky Royalty Co. with $20,000 capital stock, the organization being under the Kentucky laws.

K. U. Maguire, of the Harlan Coal Co., Louisville, has been elected vice-president of the new Morris Plan Industrial Bank, Louisville, of which he was one of the incorporators and developers. The bank is now getting ready to operate.

## MARYLAND

Mines in the vicinity of Midland are increasing their output and new men are being taken on daily. The Eagen-Loar Coal Co. has started to ship coal after making extensive improvements. Carpenters are building new mine cars to increase the tonnage.

## MINNESOTA

The ordinance for licensing retail fuel dealers has finally passed the Minneapolis City Council. It provides for a $50 annual license fee. There was some opposition on the ground that it would put small dealers out of business, but it was supported by the majority in the hope that it would assure responsibility of those in the business.

## MISSOURI

The Old Ben Coal Corporation of Delaware, with a capital of $22,000,000, has asked permission to do business in St. Louis with a capital of $463,760. The company will do a general mining business. The incorporators are Vice-President Gordon Buchanan, and Secretary A. H. Flanigan.

## NORTH DAKOTA

The North Dakota lignite mines shipped 83,397 tons between Sept. 12 and Oct. 3, as against 62,834 tons for the same period of 1924. But the interstate shipments were only 3,841 tons against 10,424 tons for the same time of last year.

The coal tipple and power plant of the Knife River Coal Mining Co., Beulah, was destroyed by fire in October, entailing a loss of about $100,000.

## OHIO

The Columbus Retail Coal Merchants' Credit Association, composed of representatives from 38 retail coal concerns in Columbus, has been formed for the purpose of gathering and distributing credit information among its members. The organization was effected after several preliminary meetings when R. H. Bell, of the Bell Coal Co., was chosen president.

After being idle for about eight months, Mine No. 1 of the Ohio Collieries Co., located at Jacksonville, has resumed operations, giving employment to almost 200 miners. A portion of the output is taken in a large railroad contract.

Announcement has been made that the Beaumont Mine, located near Chauncey, will soon resume operations, employing about 150 men. There is considerable activity in the mines in and around Chauncey and about 1,000 men are working rather steadily.

Officials of the Pittsburgh Coal Co. announce that wages paid at the mines operating under the 1917 wage scale in the Pomeroy Bend field for the month of October totaled more than $66,000. There are three mines in that field operating on practically full time.

The M. A. Hanna Co. reports net income of $223,237 for the September quarter, against a deficit of $101,880 reported in the same period last year. For the first nine months of 1925 the company reported a deficit of $292,290.

Dumpings at the Toledo docks of the Hocking Valley Ry. for the two weeks ending Nov. 4 totaled 8,577 cars, or 496,744 tons, which is considerably in excess of the records for the same period of 1924 when 7,020 cars having a tonnage of 389,395 were dumped. Up to Nov. 4 the docks handled 103,276 cars, or 7,429,776 tons, as compared with 108,575 cars and 5,945,869 tons during the same period in 1924.

Dumpings of the New York Central Docks at Toledo for the two weeks ending Nov. 4 were 3,388 cars, or 167,487 tons, as compared with 333 cars and 16,269 tons for the corresponding period in 1924. For the season up to Nov. 4 the dumpings were 47,646 cars, or 2,347,678 tons, as compared with 1,701 cars and 83,715 tons for the same period last season.

## OKLAHOMA

A windy shot was responsible for a blast which on Oct. 30 snuffed out the lives of Victor Morgan, of McAlester, and John Hunter, of Brewer, shotfirers of mine No. 4, at Brewer, the property of the Southern Fuel Co. The bodies of the miners were badly mangled, as the explosion had thrown them against the sides of the entry with enough force to break many bones.

## PENNSYLVANIA

A coal washery owned by Allison & Eddy, of New York, and located about two miles south of Tamaqua, was destroyed by fire of undetermined origin early on the morning of Oct. 28, causing a loss of $20,000. When in operation the output of the plant was disposed of to surrounding localities.

Miners in the employ of the Buffalo & Susquehanna Coal & Coke Co. in their No. 2 shaft, at Du Bois, went on strike on Oct. 23. The strike arose over a controversy relative to evictions. This company was evicting miners living in company houses at Sagamore, where the mines are being operated on the 1917 scale. The B. & S. company has made no announcement concerning its future policy with the miners.

The Benjamin washery at Eynon, know as the Rhonda, was completely destroyed by fire at 8 p.m. Oct. 28, entailing a loss of about $25,000. The washery was built by Frank P. Benjamin, of Scranton, on the site of the old Raymond breaker, which was destroyed by fire several years ago. It had not been in operation for several months.

Harry F. Sinclair, of New York, filed a petition in federal court in Pittsburgh asking removal of W. M. Wilshire and C. G. McGregor, temporary receivers of the Carnegie Coal Co., appointed by the court recently. Sinclair alleges that fraudulent transactions involving $5,000,000 in first and second mortgage bonds took place in connection with the merger of the coal company with several other coal concerns, and further says that the receivers are friendly to the president and treasurer of the company, and so would not institute legal action to regain the $5,000,000 mortgage bonds which are alleged to be unlawfully held. Sinclair's immediate interest is based on a note for $125,000 on which he was co-indorser with John A. Bell and the Carnegie Coal Co. A rule was made returnable by the judge November 12.

**A Section of the Coal-Company-Owned Town of Omar, Logan County, W. Va.**

This is one of the model mining towns of the state. It was founded by the Main Island Creek Coal Co., which was taken over by the Hutchinson Island Creek Coal Corp., which in turn was consolidated with the West Virginia Coal & Coke Co. The mines at Omar are involved in a $250,000 lawsuit which the Coal & Crane estate brought against the original operators, charging improper mining methods.

The twelfth annual banquet of mine officials and miners in the Pittsburgh district, sponsored by John L. Pratt, state mine inspector, was held in Pittsburgh, Nov. 7. W. H. Pratt, former state legislator, was toastmaster. A. C. Fieldner, superintendent Pittsburgh station, U. S. Bureau of Mines; J. E. Struble, mine inspector, H. C. Frick Coke Co., and George F. Ossler, vice-president and general manager of the Pittsburgh Terminal Coal Co., spoke.

The Red Ash Coal Co., of Wilkes-Barre, one of the oldest in the anthracite field, has filed papers in the Luzerne County Court asking that it be dissolved. There will be a hearing on the petition on Nov. 23. The operations of the company, which was incorporated in 1874, have been located for the most part in Wilkes-Barre township. The firm's coal, on the mountainside of Wilkes-Barre, is being consumed by a mine fire that has been raging for several years. The company has spent thousands of dollars in an effort to conquer the flames, but little progress has been made.

The Evans Coal Mining Co. of Fairmont, W. Va., incorporated at $25,000 recently, has leased Rosedale mine No. 2 at Poland, Greene County, which contains 700 acres of Sewickley coal land, 38 miners' houses and a large wooden tipple equipped to turn out prepared sizes. The output will be increased from 15 to 20 cars within a short time, it is announced.

The Hillman Coal & Coke Co. has bought 20 all-steel barges for the river coal trade from the Jones & Laughlin Steel Corporation. The purchase involves 3,000 tons of steel and is considered a big purchase in the industry.

The giant electric pump at the bottom of the slope in the Reliance mine, at Mount Carmel, has been undergoing extensive repairs since the anthracite suspension went into effect. Thirty men have been employed on the job. This pump, one of the largest in the coal fields, has been in steady use for several years.

The Pittsburgh Coal Co. has purchased from Katherine V. H. Wylie, three tracts of land in Elizabeth Township, Allegheny County, for $36,800.

## TENNESSEE

Howell J. Davis, of Knoxville, a coal operator, has become acting City Manager of the city, to serve during the absence of Louis Brownlow, City Manager, who has gone to Baltimore to undergo an operation. Mr. Davis acted as City Manager two years ago, immediately after the present form of government was adopted. He will serve as a dollar a year man while looking after the municipal government and handle his coal business as well.

### UTAH

"Burning of coal in large cities is nothing less than an economic folly and a social crime," said Col. H. D. Savage, vice-president of the Combustion Engineering Corp., New York City, in a talk before a meeting of Utah engineers in Salt Lake City last week. The speaker said that processes for the treating of coal had advanced to a state where gases that go off when raw coal is burned may be saved. In this way the value of each ton of coal is doubled whilst at the same time the city in which it is used is saved much trouble and expense from smoke. The speaker advocated "low-temperature distillation."

### VIRGINIA

Dudley H. R. Wigg, of the General Coal Co., Norfolk, has taken an extended leave of absence on account of illness and is under treatment at Catawba Sanitarium.

### WASHINGTON

The newest and biggest mine of the Pacific Coast Coal Co., on the Cedar River highway, five miles southeast of Renton, was opened late in October. The mine is expected to yield 2,000 tons of coal daily when it is placed in full operation. This will make it the largest mine in the state. Two tunnels were driven into Cedar Mountain during the past two years. One, from above the highway, goes straight into the mountain for about a half mile. The other comes slanting down from the top of the mountain and meets the main tunnel in the middle. From this meeting place a tunnel leads into the mountain, along the Jones seam. It is from this tunnel that the main operations will be conducted.

### WEST VIRGINIA

In addition to resuming operations at its Coalton mine on Oct. 15, the West Virginia Coal & Coke Co., through E. L. Michie, general manager of its West Virginia division, announces that preparations are being made to put all the coke ovens of the company in blast, including those at Harding, as well as at Coalton, and that as soon as working forces can be built up to the requisite strength the production of the company in northern West Virginia will be on a larger scale than at any time in recent years. All mines of the company except those at Junior and Mabie are now in operation. The Harding mine has been on a part-time basis but it is now proposed to operate it every day in the week.

The following West Virginia coal companies have surrendered their charters and discontinued business: C. G. Hartin Coal Co., Mullens Smokeless Coal Co., Laurel Coke Co., Bengal Co., Goodin & Barney Coal Co.

The New England Fuel & Transportation Co. recently put into blast a battery of 60 coke ovens at Federal No. 1 mine, at Grant Town.

A circuit court jury at Huntington on Oct. 28 found a verdict for $122,500 in the suit of Charles W. H. Crane, of Cincinnati, against A. J. Dalton and J. A. Kelly, growing out of a Wyoming County land deal. Two previous hearings in the circuit court had resulted in hung juries. The sum is approximately one-half the amount asked by the plaintiff, who claimed he was due $5 an acre under terms of an agreement under which title to between 49,000 and 50,000 acres of land was acquired, and upon which he held an option from trustees of the Cole and Crane estate.

Operations were suspended indefinitely at No. 1 and No. 2 mines of the Galloway Coal Co., at Galloway, twelve miles west of Grafton on Oct. 31, according to an announcement by F. B. Findley, superintendent. About 500 men were thrown out of work. The mines have operated for several years under the union scale, filling contracts for railroad fuel and for lake delivery, but officials of the company state that the contracts have expired and that the company can no longer afford to operate at the prices now prevailing. The mines have a capacity of about 90 cars a day.

The Alma Thacker Coal Co. mine, located near Matewan, resumed work Nov. 2, after having been closed down for about eighteen months. One hundred and fifty men are finding employment in the mine. It has a capacity of 800 tons of coal per day. Williamson coal men have leased the mine and equipment from the Columbus owners. Every mine in the Williamson district is now working at capacity.

V. S. Veazey, of Fayetteville, has filed a voluntary petition in bankruptcy in the federal court for the southern district of West Virginia. Mr. Veazey has been engaged in operating mines at Glen Jean, in Fayette County, as well as at Robson. Only recently the Glen Jean mine was sold at public sale, but the Robson property is still retained by Mr. Veazey. Liabilities are listed at over $100,000 and assets, including the Robson leasehold are approximately $85,000.

### WYOMING

The Rock Springs store of the Union Pacific Coal Co. was destroyed by fire Oct. 31, the loss being close to $100,000. The exact cause of the fire has not been determined. Practically all of the important records of the store were saved. The company operated a complete department store with a stock of between $60,000 and $75.000. On the following Monday morning a temporary store was opened in an old school building near the scene of the fire.

The second October payroll in the Rock Springs district is said to have been the largest in the past four years. It is reported that the miners' payroll from the four Union Pacific mines in Rock Springs alone amounted to more than $77,000.

## Traffic

### More New B. R. & P. Coke Rates Are Approved

The New York Public Service Commission has approved new rates on the Buffalo, Rochester & Pittsburgh R.R. on coke and coke breeze from Buffalo to Lincoln Park and Rochester, $1.39 (including connecting lines switching charge not exceeding 38c. per ton, not heretofore included in the $1.39 rate); to Beaver, Riceville and West Valley, $1.23, reduction 3c.; to Ashford, $1.39, increase 13c.; effective Nov. 29.

### Allows Emergency Rates on Coke

Establishment of lower rates on coke and coke breeze from the Birmingham (Ala.) district to southeastern Michigan destinations east of the Grand Rapids & Indiana division of the Pennsylvania System and south of the line of the Pere Marquette R.R. has been permitted by the Interstate Commerce Commission over the protest of Illinois, Indiana and Wisconsin byproduct coke interests, who opposed granting the Alabama & Great Southern and Louisville & Nashville railroads permission to make the reductions effective on 10 days' notice. The new rates are 50 and 75c. per ton higher than the rates from Chattanooga, Tenn., to the same destinations. The petitioning carriers pled the emergency created by the anthracite strike as justification for the proposal to make the rates effective on less than statutory notice. The existence of such an emergency was denied by the opponents, who stated that coke plants at Indianapolis, Terre-Haute, Ind., and Granite City, Ill., "are now moving large quantities of coke into Michigan."

## Obituary

**Robert Ivell**, 81, retired coal operator, died recently near Harrisville, Pa. He was employed when young in English coal mines. In 1881 he went to Pennsylvania and operated mines in Cherry and Venango townships of Butler county, retiring 20 years ago. He leaves his widow and seven children.

**Ashley E. Woolridge**, one of Clearfield County's best known citizens and most successful coal operators, died at his home in Woodland, Pa., Oct. 29, aged 68 years. His parents were among the early settlers of Clearfield County. He served two terms as county commissioner of Clearfield County and during the past ten years was among the best known coal operators in the Clearfield district, having started coal development many years ago. He is survived by three daughters and three sons.

**Fred H. Harwood,** 62, a prominent Chicago coal dealer, died at his home in Lankershim, Calif., Oct. 23. He was a former president of the New Kentucky Coal Co. and for a number of years was traffic manager of the Illinois Coal Traffic Bureau in Chicago. From 1904 to 1909 he was coal traffic manager of the Illinois Central R.R., having been twenty-two years in the service of that company.

**William F. Aldrich**, who came to Alabama in 1874, and together with his brother, Trueman H. Aldrich, founded the mining town of Aldrich, in Shelby County, which is now the center of extensive coal-mining operations, died at Birmingham Oct. 30. Mr. Aldrich moved to Birmingham in 1912, since which time he had been engaged in handling mineral properties. He at one time represented the Fourth Alabama District in Congress.

## Coming Meetings

**American Institute of Electrical Engineers.** Annual meeting of Lehigh Valley section at the Schuylkill Country Club, Pottsville, Pa., Nov. 13, at 6:30 p.m. Chairman, W. H. Lesser, Frackville, Pa.

**Harlan County Coal Operators' Association.** Annual meeting, Nov. 18, at Harlan, Ky. Secretary, E. R. Clayton, Harlan, Ky.

**West Virginia Coal Mining Institute.** Fall meeting, Nov. 24 and 25 at the Hotel Morgan, Morgantown, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

**American Society of Mechanical Engineers.** Annual meeting at New York City, Nov. 30-Dec. 3. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**Fourth National Exposition of Power and Mechanical Engineering.** Nov. 30 to Dec. 5, at Grand Central Palace, New York City.

**Coal Mining Institute of America.** Annual meeting, Dec. 9-11, Pittsburgh, Pa. Secretary, H. D. Mason, Jr., P. O. Box 604, Ebensburg, Pa.

**American Mining Congress.** Twenty-eighth annual convention, Dec. 9-11, Washington, D. C. Secretary, J. F. Callbreath, Munsey Bldg., Washington, D. C.

## Industrial Notes

The Cleveland office of the **Sullivan Machinery Co.,** hitherto at Room 701, Rockefeller Building, has been moved to Room 1506 in the same building in order to secure needed additional space. R. T. Stone is manager. The office in Sydney, New South Wales, of which R. D. Willets is manager, has been moved from Australasia Chambers, 3 Martin Place, where it had been for 15 years, to Kembla Building, Margaret Street.

C. G. Wennerstrom, formerly of **Allbright-Noll Co.** of Chicago, has recently joined the engineering force of the **Foote Bros. Gear & Machine Co.** of Chicago. Mr. Wennerstrom has an extensive engineering and sales experience, including about seven years with the Davis-Watkins Dairy Manufacturing Co., associated with Mr. Davis, who is now president of the Foote Bros. Gear & Machine Co.

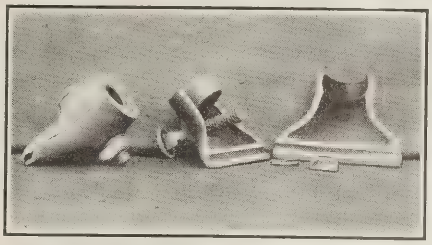
The Russian Soviet Commission visiting this country to study coal mining methods and to purchase American machinery for Russian mines, ordered six type 5 BU and one type 6 BU Joy Loaders from the **Joy Machine Co.,** of Franklin, Pa. These machines are now being shipped and should be in service in seven Soviet mines within ninety days.

# New Equipment

## Clamp with Only Two Castings Is Easy to Install

Buddy Clamp is the name given to a new trolley clamp recently placed on the market by the Electric Railway Equipment Co., of Cincinnati, Ohio. The clamp is claimed to be quite simple and rugged, although it does not incorporate a self-aligning feature.

The device is made of two castings bolted together. One of these castings is tapped for the usual size insulator stud and matches up with the other casting by a modified ball and socket joint. The whole unit can be installed easily and requires no special wrench. The bolt used to clamp the two sections together is a sherardized carriage bolt. The square section under the head fits into one half section of the clamp, so that when the nut is applied the bolt does not turn.



**Simple Clamp Is Easy to Install**

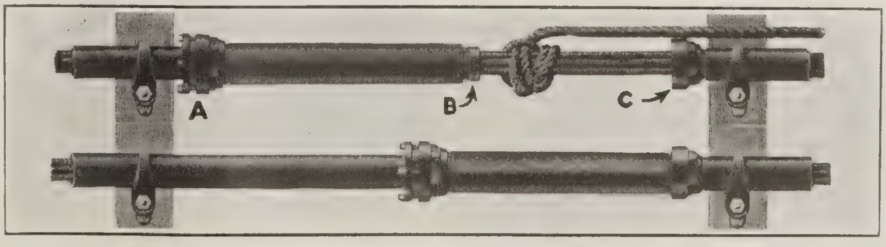
Only two castings make up the clamping and attachment parts of this little device. A carriage bolt holds the two parts together and tightens the clamp on the trolley wire.

## Fitting Makes It Easy To Pull Wires Into Pipe

It usually is difficult to pull wires into long sections of conduit even though the pipe be of ample size to accommodate the wires. Unless junction boxes are installed this work always has been difficult. To reduce both the cost and space required for pull boxes, the V. V. Fittings Co., Philadelphia, Pa., has placed on the market what is known as a "Straight Line Pull and Splice Fitting," shown in the accompanying illustration. This fitting consists of three parts: A stuffing box and gland with packing *A*, a bushing *B*, and an end connector *C*. For the connection between the stuffing box and end connector a length of conduit is used, having a diameter large enough to go over the conduit that the wires are pulled into. For example, if the main conduit is 1¼ in. in diameter, a piece 1½ in. in diameter will be used for the sliding sleeve between the fittings.

In applying this fitting, the stuffing box and gland *A* are screwed on to the end of the sleeve and they are pushed on over the conduit out of the way. Then the bushing *B* is put on the end of the main conduit in front of the sleeve and the end connector *C* is placed on the end of the conduit on the opposite side of the pull opening.

After the wires have been pulled in, the sleeve is moved up over them and screwed into the end connector and the stuffing-box gland tightened so as to make a watertight connection, as shown in the lower figure. In addition to using the fitting as a pull box, it may also be used as a junction box in which the wires are spliced. The use of this fitting not only provides greater convenience in pulling in the wire than do pull boxes, but it also occupies much less space. The fittings are made of cast iron, black or galvanized finished in standard conduit sizes from 1 to 6 in.



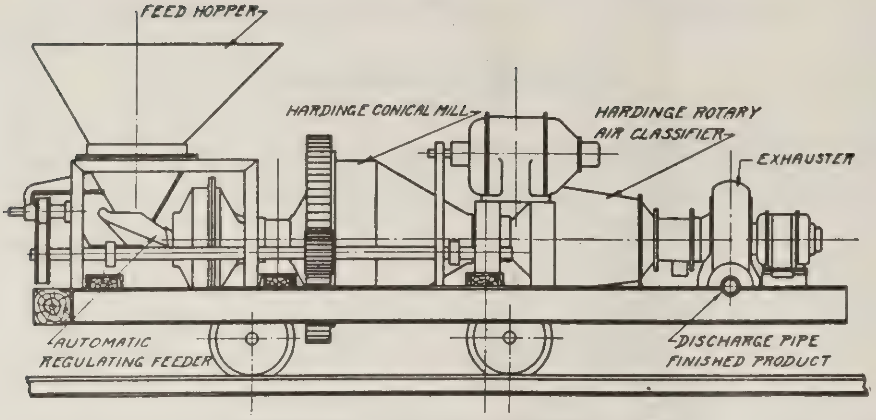
**Wires May Be Pulled at Various Positions**

A section or piece of sufficient size to slip over the conduit is supplied with fittings so that an opening can be provided for pulling the wires.

## Combined Grinder and Duster Saves Time and Money

In order to facilitate so far as possible the rock dusting of mines, the Hardinge Co., of York, Pa., has recently placed on the market the combined pulverizing and dusting unit shown in the accompanying illustration. This machine both grinds the inert dust and distributes it within the workings. It consists of a feed hopper, automatic regulating feeder, a Hardinge conical mill, a rotary air classifier and exhauster, and a discharge pipe by which the finished dust is distributed.

This combined pulverizing and dusting unit is a decided departure from most other types of machines at present employed. It possesses certain well defined advantages, however, that commend it for use in many places in both large- and small-scale operations. Rock, crushed but unground, is supplied to the machine in any convenient manner and placed within the feed hopper. An automatic feeder regulates the flow of this material through the pulverizer which is of the conical ball-mill type.



FEED HOPPER
HARDINGE CONICAL MILL
HARDINGE ROTARY AIR CLASSIFIER
EXHAUSTER
AUTOMATIC REGULATING FEEDER
DISCHARGE PIPE FINISHED PRODUCT

**Arrangement of One-Car Pulverizing Unit**

The feed hopper, automatic feeder, conical ball-mill, rotary classifier and the exhauster are all mounted on one mine car truck. As an alternate arrangement giving slightly greater capacity the hopper and feeding device may be placed on a separate truck. A dust-collector may also be employed if it is desired to spread the dust by hand in places that are inaccessible to the machine or its discharge hose, or to use it in another mine.

From the mill the product is withdrawn and the coarse material separated from the fine by means of the rotating classifier. From this latter piece of equipment, the dust is blown through a nozzle and directed toward the mine surfaces that are to be dusted. The suction of the fan beyond the rotating classifier draws the air into the mill, partly through the feeder but mainly through a central pipe which is kept open. This air in the central pipe conveys the oversize back to the mill in the same way as is accomplished in stationary units of this type.

This portable unit occupies but little more space than an ordinary dusting car. Since the operation of mill and classifier is extremely simple, skilled workmen are not necessary for its manipulation and the machine requires little more attention than need be paid to an ordinary blower. It is far easier to regulate the feed of granular material to the machine than the feed of dust to an ordinary rock dusting car, because any slight degree of moisture in such dust has a tendency to cause packing. An even feed is vital if dusting is to be done effectively or economically.

### Saves Much Expense

Since with this device both pulverizing and dusting are accomplished simultaneously, a considerable saving is made both in first cost and operating charges. The expense entailed for a surface plant is eliminated and all work of dusting is done by one crew underground in place of two, as is necessary if a separate grinding unit is installed on the surface.

In case dust is desired in bulk, the portable unit may be supplied with a small dust collector similar to that used with a surface plant. This is mounted on a stand and can be moved with the car when hand dusting in inaccessible places is desired, or it may be used for filling trough barriers or sacks.

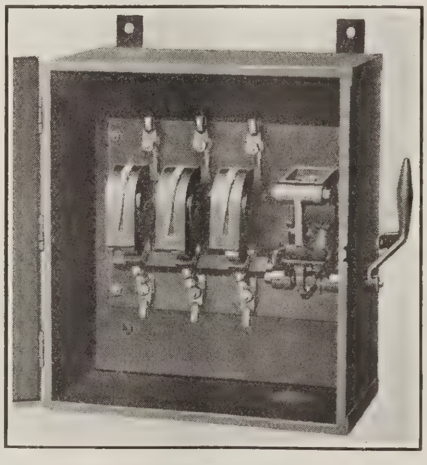
The portable unit may be supplied either with a nozzle attached direct to the blower outlet, or with a flexible hose so that the operator may reach places more or less inaccessible up to 75 to 100 ft. distant from the car. Furthermore outfits of this kind may be built in one- or two-car units. The two-car unit holds more rock, and has greater capacity. The pulverized product from any of these machines will run approximately 60 per cent through a 200-mesh screen, or finer if desired. A finer grinding is to be preferred as it reduces waste and is more effective in the case of an explosion. The finer the grinding, however, the lower will be the capacity, other conditions remaining the same.

---

## Manually Operated Switch Opens Quickly

A manually operated contactor recently placed on the market by the General Electric Co. and listed as CR-1049 is a new motor-circuit switch for easily disconnecting a motor and its control equipment from the line under practically all conditions except a dead short circuit. It consists of contact elements mounted on insulated shafts and connected through a snap-action mechanism to the operating handle on the outside of a sheet-steel inclosing case.

Both case and handle can be locked in the open position, thus preventing unauthorized persons from closing the device. No provision is made for locking the handle in the closed position. The contactor will open under load with full safety to the operator. Silver contact tips are used on all sizes with the exception of the 50-ampere switch thus reducing contact resistance. The new contactor is being made in four sizes ranging from 50 amp. to 300 amp.



**Opens Heavily Loaded Lines**

This quick-break switch is fitted with contactors. A snap-action type trip controlled from the outside of the inclosing cabinet provides safe operation.

---

## Trade Literature

**Properties of Steel Filler Rods for Gas and Electric Welding.** Chicago Steel & Wire Co., Chicago, Ill. Pp. 28; 4x9 in. The contents of this booklet represent findings of the research department of this company and should prove interesting to those interested in fusion welding. Copy sent on request.

The Delta-Star Electric Co., Chicago, Ill., has issued a bulletin on **High Tension Bus Supports,** containing 48 pp. and 119 illustrations, giving detailed dimensions of supports up to and including 120 kv. Copy sent on request.

Dings Magnetic Separator Co., Milwaukee, Wis., has issued a folder describing and illustrating the uses of its **Separator** in coal mining and other industries.

The Cecil R. Lambert Co., Detroit, Mich., has issued an interesting brochure on **Conveyor Applications.** Copy sent on request.

**Aerial Tramways.** A. Leschen & Sons Rope Co., St. Louis, Mo. Catalog No. T-25. Pp. 51; 6x9 in.; illustrated. This interesting catalog is divided into four sections. Section I gives general information concerning the adaptability, operation and fundamental features of the Leschen aerial tramways; sections II and III cover detailed descriptions of wire-rope tramways, and section IV includes the design and manufacture of Leschen aerial tramways.

Electrical Engineering Service, New York City, has issued a folder describing and illustrating its **Combination Ammeter, Voltmeter and Ohmmeter.** Copy sent on request.

**Underwriters' Laboratories Report on Simplex Track Jacks.** (Safety Appliance No. 286.) Templeton, Kenly & Co., Ltd., Chicago, Ill. Pp. 58; 6x9 in.; illustrated. Covers tests and tabulations on man-power and safety for track jacks.

**Lufkin Tools.** The Lufkin Rule Co., Saginaw, Mich. Catalog No. 4. Pp. 95; 4½x6½ in.; illustrated. Describes the small tools manufactured by this company, giving weights and prices.

**Marion Type "EB" Soot Blower. Marion Machine Foundry & Supply Co., Marion, Ind. Bulletin No. 220. Four-page folder describing and illustrating this new blower for water-tube boilers. The blower is similar to this company's former planet soot blower, except that it now has a valve-in-head independently operated.**

Republic Flow Meters Co., Chicago, Ill., has issued a four-page folder describing and illustrating its new **Electrical Level and Pressure Indicator and Recorder.**

The Marion Steam Shovel Co., Marion, Ohio, rceently issued Bulletin 316 on its new **Marion Model 125,** steam and electric, illustrating and describing the new shovel.

**Capacitors.** General Electric Co., Schenectady, N. Y. Bulletin GEA-77. Pp. 24; 8x10 in.; illustrated. Describes the value of this device in power factor correction on electric generating and distribution systems and for direct installation at motor terminals on low voltage circuits.

The Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., has issued the following literature: Leaflet L-20253, describing its manually and electrically operated oil circuit breakers, types D, F-1, F-2 and F-3; leaflet L-20138, describing its new type SC steel clad distribution transformers for single phase service on small isolated outside substations feeding from high tension lines; circular 1737, bearing the title Adequate Lightning Protection, describing its new Autovalve lightning arresters; L. 20044-B, which is a revised publication on LD static condensers and covers the subject of losses due to low power factor, their correction and the economic application of static condensers.

**The Hardinge Rotor Spray** for gas scrubbing, air conditioning, absorption, concentration, mixing, aeration, heating and cooling. Hardinge Co., York, Pa. Bulletin No. 29. Pp. 12; 8 x 10½ in.; illustrated.

Volume 28 NEW YORK, NOVEMBER 19, 1925 Number 21

## West Virginia Takes the Plunge

MERCHANDISING HISTORY was written when members of the Smokeless Coal Operators' Association of West Virginia decided to support their contemplated invasion of the New England domestic market with a combustion-engineering service. Heretofore the the average low-volatile producer has been as backward in marketing methods and appreciation of public contacts as was the anthracite industry during its long somnolence. Now, to widen their markets, the smokeless operators plan a service similar to that inaugurated by anthracite when it awoke to the menace of dwindling demand. They, too, propose to teach the consumer how to burn their coal efficiently and to smooth away the sharp angles of complaint.

The advantages of such a service are too obvious to call for comment. These advantages, however, cannot be fully realized unless and until certain less patent, but none the less controlling, drawbacks have been overcome. In New England, the smokeless producer is faced with the job of establishing consumer acceptance and of breaking down retailer resistance. Tradition has bound both householder and retail distributor to anthracite. They may abuse and damn hard coal, its quality, its preparation and its price, but it is still their favorite and favored fuel—and neither the fervor of the New England Governors' Fuel Committee nor the missionary zeal of Mr. Hultman can change that situation over night.

The retail distributor will handle other fuels during the present emergency as a public duty, but there will be little enthusiasm for the task. He will be ready—and willing—to forget their existence as soon as anthracite production is again in full tide. One thing only will chill this desire to ignore other fuels after the strike has ended. That one thing will be a real, an insistent demand upon the part of his customers for more of the fuel the emergency forced upon them. The New England retailer loveth anthracite much, but he loveth his customers more.

It is, of course, the work of the smokeless coal bureaus to create and to fire such a consumer demand. Anthracite has been burned so long in New England that proper handling in the domestic heating plant has become instinctive. These bureaus must teach the consumer a new combustion technique. That in itself is no easy task where habits have been ingrained by generations. If the New England character is as fixed in its mold as common report states, it will take far more than the modest sum which the association has provided for this campaign.

But the work is still further handicapped at the start by the price situation. The consumer, deprived—without consultation or consideration—of his accustomed anthracite, is in a resentful mood. It will add nothing to the kindliness of the reception or to the fairness of the trial he gives another fuel if the price charged approximates what he normally pays for hard coal. In his mind, it will be adding insult to injury. Therefore, if West Virginia desires to make a permanent conquest of New England, mine prices on prepared sizes must come down or the energies of the campaign must be concentrated upon mine-run.

We are considering here long-time merchandising, not hit-and-run speculative selling. If the latter be the goal, the proposal indorsed at Boston is an expensive and meaningless gesture. The producer may be able to justify a $6 or $7 price on lump, but New England will remain unconvinced. He cannot justify the spread between $6 lump and $2.25 mine-run—especially in view of the eagerness with which he now is willing to book orders for the latter size at $2.50. He may be able to justify all his prices, but he is not helping his cause in New England. To appear before the public in the guise of a profiteer—even if the disguise is false—is too big a handicap for any sound merchandising campaign to carry.

## Checking Plans for Safety

ONE COAL COMPANY puts the words "Safety, the first consideration" on all its maps and plans as a continual reminder of the importance of safety. It would be well if, in recognition of this obligation, large manufacturers had a safety man who would check all important drawings, if not all drawings, for safety, and if smaller companies were to require a signature after the words "Inspected for Safety" even if the same engineer who signed a general approval were the man appointed to affix his name as vouching within reasonable limits for the safety of the device. Unfortunately, rarely can a device be made wholly foolproof.

## More Electric Power

MOST OF THE EXPANSION in the coal market will come from increased use of electric power, and the coal operator should co-operate with the electric utility industry in promoting increased power consumption.

In the West the soil is made to give good results by judicious irrigation. Unfortunately irrigation may be extremely injudicious. The strength of the soil may be leached away and fields may be insufficiently drained. But with proper management arid land may be greatly benefited by irrigation. Farms on which the rain but rarely falls, when irrigated properly, seldom fail to produce a bumper crop.

On the other hand, in the East there is no irrigation and the crops are uncertain. The lack of rain may appreciably retard plant development and the farmer never knows what he will be able to produce. With some means of furrow or of subsurface irrigation or, if vegetables are planted with some provision for spraying from pipes, it would be possible to get a good crop every year. The only variable remaining would be the sunshine.

The U. S. Department of Agriculture as long ago as 1917 had issued three bulletins on this subject, one on the surface irrigation of Eastern farms, one on irrigation in Florida and one on spray irrigation. Says Milo B. Williams in the last of these brochures:

> Within the past ten years the spray irrigation method has been adopted over a wide area in the United States especially in the Atlantic Coast States from Massachusetts to Florida. Many spray irrigation plants have been installed in the North Central States while scattered installations can be found in practically all Southern and Western states.

The Department says that it has received many letters asking for information regarding irrigation in Eastern localities. It appears that the pump and pipe manufacturers, and the central station could make profitable use of this irrigation movement. It should be called to their attention. In that advance the coal industry would profit.

## Eye as Victim or as Culprit

WHICH ARE THE MORE important, eye accidents or accidents from faulty eyes?

At a recent executive meeting of the American Society of Safety Engineers, which is the engineering section of the National Safety Council, a member of the executive board said he had seen only one workman in either the construction or the machine industry who wore spectacles to correct his eyesight. Yet in that executive board as then assembled—and twelve were present—all but two wore glasses of one type or another.

He could not believe that the average workman had any better eyes than the men in that executive board and if they had not they were exposing themselves to many hazards. The Society mentioned is preparing to make a research into the "Influence of Faulty Vision on Accidents." It seems that the miner also must often fall a victim to faulty vision. Working in the dark, with the insufficient light of a single lamp, his condition must be perilous if his vision is defective. It is quite likely that accidents to the eye are not nearly so frequent or so dangerous as accidents caused by defective vision.

## Only One Size for Coal

SOME TIME IN THE FUTURE coal will be prepared at the mine in only one size—slack—unless, indeed, it is pulverized before shipment for use in powdered-coal furnaces. The coal industry should hasten that day. Operators should everywhere be studying the possibility of a greater use of fine sizes whether as slack or as dust.

When that time comes coal will be handled at the face with less care than today, pneumatic transportation may be adopted and coal may even be taken to market hydraulically through pipes. Coal will be coal then, no matter what is its size. No one will have to consider in that day whether he can dispose of the rest of his product, if he puts his output over any given screen. It is probable that all the coal will be crushed at the mine because some of the consumers, especially those who use it for heating, may not be equipped for crushing their fuel. The power plants at that time may be all at the mines so that only the coal needed for heating will be "shipped' by pipe or car, and perhaps not even that will have to be transported for it may be converted into gas before shipment.

To make these developments possible much remains to be accomplished. At present coal should be transported to the local power stations wherever energy is needed far from a natural fuel supply. Probably it will be necessary to take coal to gas houses near where the gas is to be used unless the load is uniform the year round, which is not the case, of course, where gas is used for house heating as it is in a degree in all cities. The demand for gas for cooking is less seasonal, and where so used the possibility of piping it with profit is increased.

Certain it is that a much larger use of small coal can be made, and if the market for it improves it will be possible to raise the price to such a figure that it will be profitable to mine coal to supply the slack market alone. When that time comes for the high-volatile region one of its greatest difficulties will be solved. Fortunately, the low-volatile mines have been able to operate at all times on a run-of-mine basis.

However, he would be foolish indeed who would let the interest in the future market so influence him as to neglect preparation. So long as present equipment is used for burning coal, careful sizing will pay. No one will do well to let a distant ideal, to which we shall for years only approximate, interfere with a prudent effort to give the present market the service it demands.

## Steam Better than Water

AS A RESULT of power-house economies and the skill shown by steam-station designers, hydro-electric development seems likely to be kept in check. Where, as at Niagara Falls and on the Pacific Coast there are abundant opportunities for the manufacture of hydro-electric power and no coal, there can be no conflict between water and steam as a source of power. But in other places the outcome will favor the use of steam.

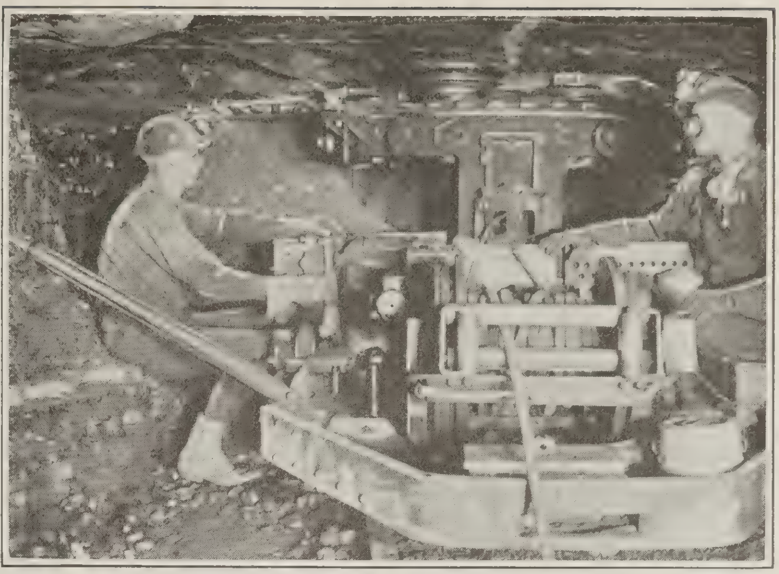
It is usually the case that hydro-electric power is generated just where no one would think of using it, in mountain fastnesses where no one lives and where there are few farms. Coal, however, many years ago surrounded itself with a large and industrious population. "White coal," or water power, might eventually do the same, but that takes time.

Droughts recently have interfered with the operation of hydro-electric systems and have made it necessary to add to the number and size of the steam auxiliaries, thus adding to the cost of water power. Steam-station engineering has developed to such a point that stations costing $125 per kilowatt of capacity have been able to produce one kilowatt-hour for six mills.

Opportunities exist for further improvement of steam plants. They are low in overall efficiency whereas hydro-electric power borders on a maximum. So, after all, the savings in the economy of steam at central station plants is not going to be altogether a disadvantage. It is going to prevent hydro-electric power from making further development. The fact that the best sites have been exploited and the jealousy with which the public watches all hydro-electric developments, especially where they detract from scenery of great natural beauty, are other reasons for feeling assured that steam power will always be a strong competitor to water.

# Turret-Type Cutters Improve Coal Mining in Kentucky

## Three in One Mine Save Labor Protect Weak Roof and Keep Coal Cleaner — Another Makes the Amburgy Seam Marketable



**By Alphonse F. Brosky**
Assistant Editor of *Coal Age*,
Pittsburgh, Pa.

THE FAR-REACHING utility of coal-cutting machines that can operate in the top, bottom or middle of a seam is well demonstrated in two eastern Kentucky mines. Machines of this turret type that can cut across a face from a track position greatly reduce the time and labor factors of mining. Cutting at the top they protect a weak roof from the shattering effect of explosive. Cutting at any level they help to remove slate bands from a seam, thus not only reducing ash content of coal shipped but preventing the waste incident to operating a machine in coal itself.

The first two benefits were the ones mainly sought by the Consolidated Fuel Co. when it installed three turret machines in its Elsie No. 2 mine on Smoot Creek in Letcher County. The third was the principal consideration at the adjacent mine of the Stafford Coal Co. In both mines the arc cutters have "earned their keep" and in neither have the machines been given an opportunity to reach their full capacity. Expansion of operations will do that later.

The Consolidated Fuel Co., by using its three machines for cutting above the coal in a soft roof slate, has largely solved the problem of separating this material which otherwise comes down and mixes with the coal. In this mine, halfway between Blackey and Whitesburg, the Hazard No. 4 seam, 56 in. thick, is worked. The thickness of the cover varies from 600 to 800 ft. Rooms are driven 15 ft. wide and 200 ft. long on 50-ft. centers. Entries are mined 10 ft. wide.

The region of this seam lies roughly between Hazard and Whitesburg. The thickness of the seam is greatest near Whitesburg. In the immediate vicinity of Hazard the seam is 3 to 3½ ft. thick, having a bottom of hard smooth slate which is called "jack rock." In the Elsie No. 2 mine and throughout the vicinity, where the coal is thicker, the jack rock, 4 to 6 in. thick, is underlaid by 12 to 14 in. of bottom coal which is absent where the seam is thinner.

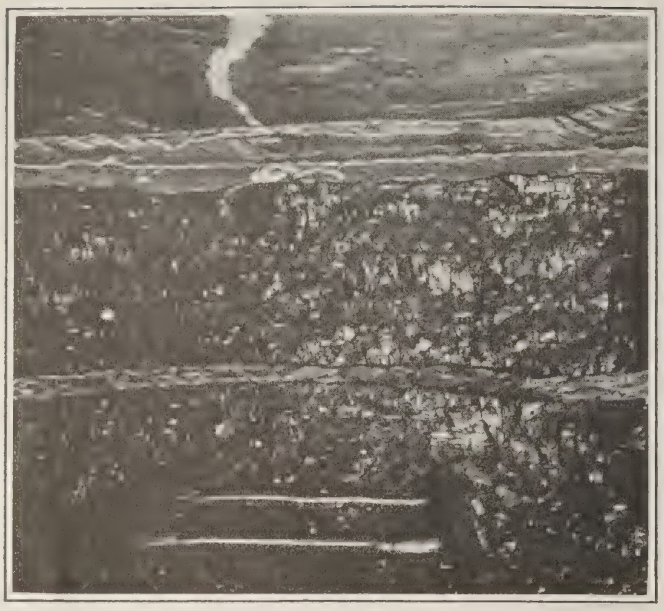
The top above the seam is not uniform in the Elsie No. 2 mine. This creates varying mining conditions. In wide areas the coal is overlaid by a band of soft slate, the maximum thickness of which is 6 in. Because of it the turret machines were installed. In other parts of the mine the top is of a smooth harder slate, which is taken down after the coal is mined. The slate in some places is rough without regular cleavage and contains kettle bottoms. In places these shales attain thicknesses of 6 to 8 ft., being capped by a deposit of sandstone. Elsewhere the shales disappear leaving in their place the sandstone which occasions little worry to the management. Sometimes a draw slate is found between the sandstone and the coal. This multiplicity of roof conditions partly led to the adoption of the arc cutting machine. Mainly, however, the decision was dictated by the need of keeping the coal free of shattered particles from the soft slate top.

Throughout most of the region there lies, immediately above the 6-in. layer of soft slate, a 4-in. layer of hard slate which must be taken down. The latter does not contribute a higher ash content to the coal because a span of this material stays in place at least until after a cut under it is loaded. An illustration typical of this condition appears in the accompanying

CUTTING MACHINES which operate from a position on the mine track are gaining favor. This is chiefly due to the saving in time and labor in making ready to cut and also to move which these machines effect, accounting for their greater productivity. A machine which cuts a horizontal kerf at some level above the floor automatically falls into this class for it must be built heavily enough to hold against a thrust above its center of gravity and consequently must be supported by rails. In the future machines of this type are bound to be used more and more to cut out bone and ash, thereby widening the markets of some of our coals. They may redeem "lost" mines.

---

By the use of cutters such as the one shown in the headpiece the Consolidated Fuel Co. has turned into a favorable condition what before caused it considerable difficulty in drives for cleaner coal. This machine is shown cutting out a soft roof slate which always had come down and mixed with undercut coal. And, of course, a fair quantity of lump coal is added to the recovery by cutting in the slate. This place, which is 10 ft. wide, was cut in four minutes.



**A Typical Condition in Elsie No. 2 Mine**

About 14 in. from the floor is seen the 4-in. band of "jack rock" which is lifted out of the cut after the top bench is loaded and before the bottom bench is mined. Usually the top bench is shot and the bottom bench dug. A soft slate is directly above the coal. Harder slate is above the soft, which is taken down after the cut is loaded and above that the rather solid roof slate.

halftone showing a room face. As this hard band sometimes forms the top of the seam the cutting machine helps to prevent the shattering of this band of hard slate and upper strata during the shooting.

Little need be said about the actual operation of cutting because with these details the reader is familiar. The machine cuts in the soft slate wherever this material forms the top and in the coal where sandstone or hard slate forms the roof. It works at approximately the same rate in either material easily cutting 25 to 35 places, 10 and 15 ft. wide in a day. The output of the Elsie No. 2 mine is now about 800 tons. All of this coal is cut by the three machines. However, as they do not work under the same conditions the output of each varies. The crews do not work a full 8-hr. shift. If they did the three machines should be able to average 1,000 tons a day without difficulty.

The occurrence of the jack rock in the seam and its effect on shooting are other factors which may have influenced the adoption of this type machine. If the coal were undercut the shots would bring down the jack rock with the top and bottom benches, a condition to be avoided for obvious reasons. Furthermore, the jack rock by virtue of its comparative resistance and location in the seam is likely to reduce the effectiveness of the shots.

As it is now, a 7-ft. cut is made by an 8-ft. cutterbar. Two 1½-in. rib shot holes 7½ ft. deep are charged with either one and a half or two sticks of permissible explosive, bringing down the top bench of coal which is loaded first. The shooting of the upper bench breaks the jack rock making it easy to load, and springs the bottom bench sufficiently to produce large lump coal. Top cutting simplifies what otherwise would be a difficult condition for shooting.

The Stafford Coal Co., opening up its mine near Elsie No. 2 mine operates in the Amburgy seam which is below the Hazard No. 4 seam. It is using a low type arc-cutting machine for a different purpose. It is said this company is the only producer in Letcher County mining the Amburgy seam. Aside from a 3- to 5-in. bone parting which divides the seam into a 16-in. top bench and a 27-in. bottom bench, the seam is low in ash. The roof is generally sound and self-supporting.

This band of bone strictly is not a parting because it is more or less burnt to the upper and lower benches and, therefore, cannot be separated satisfactorily. This coal seam is fairly persistent as to thickness and has a good roof but little effort has been made in the past to mine it. The fact that wants are known to occur in the seam may be partly responsible for this but the main reason is the bone band within the seam.

### Other Methods Failed

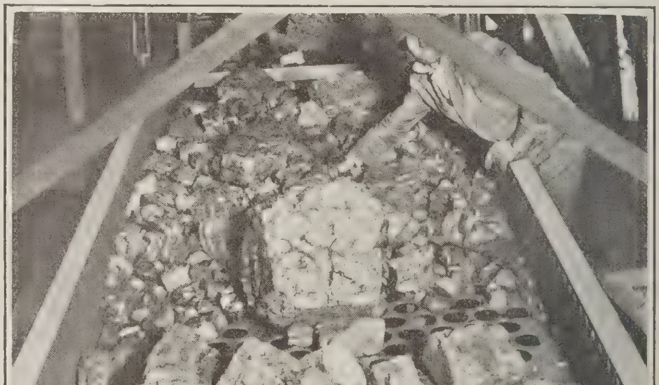
In the several attempts made to work this seam both pick mining and undercutting methods were tried. In neither case could enough of the bone be removed by hand to provide a low-ash coal. The Stafford Coal Co. reopened a mine abandoned by a predecessor, with the intention of cutting out the highly objectionable band of bone. And this is precisely what the company is now doing with the aid of the machines.

Rooms are driven 16 ft. wide and 200 ft. deep on 50-ft. centers. Room pillars are recovered immediately upon completion of rooms by open-end cuts on the backs of the pillars, the machine retreating toward the entry. In the pillar work as well as in rooms the machine (alternating-current drive) is used. Twenty-five-pound rails are laid on steel ties in rooms and pillar sections for the machine.

After the bone is cut out, requiring about 5 min. for a place 16 ft. wide, the upper bench springs sufficiently to require no shooting. Large lumps (splint coal) are dislodged from the upper bench by pick mining. Occasionally a pop shot is needed to loosen the coal in this bench. Three sticks of permissible explosive in two shots are sufficient to produce good lump coal.

As this mine is in the early stages of its development it has not been possible to determine how much work this machine will do in a full shift under the conditions described. It is believed that the machine should cut at least 25 rooms in one shift.

It is commonly thought that machines which cut a kerf above the floor add to the danger from coal dust ignition. This of course holds where the machine is

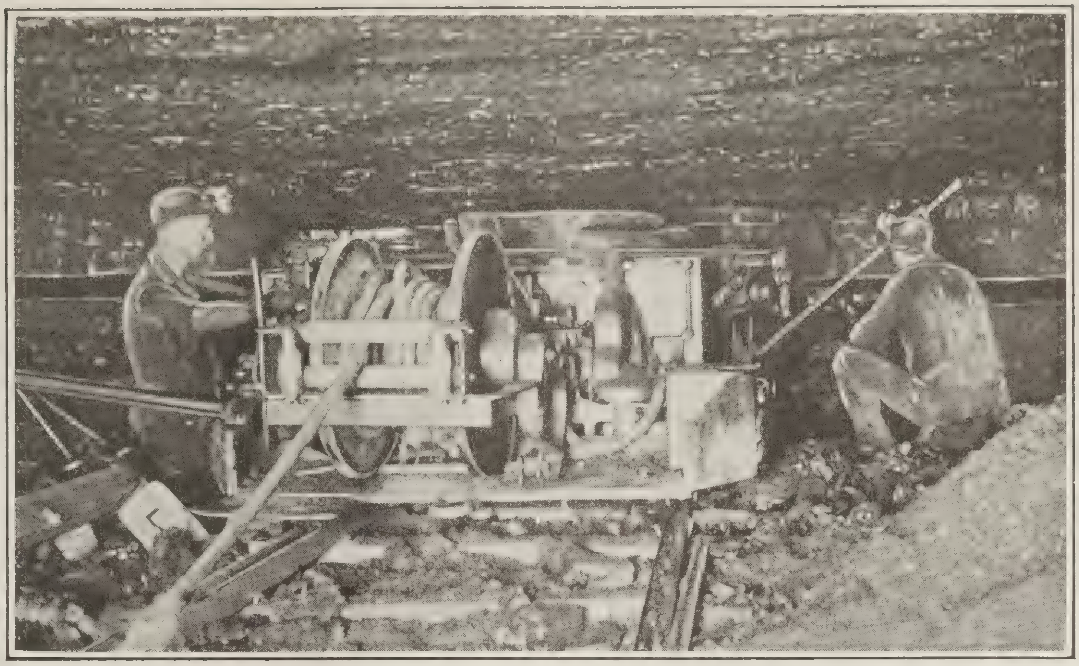


**Shaker Screen at Elsie No. 2 Mine**

The Consolidated Fuel Co. believes in good preparation and, therefore, has installed that equipment which will bring this about. This coal comes from the Hazard No. 4 seam.

**Cutting Out Bone**

This machine, and it alone, makes the Amburgy seam in this mine marketable. About 16 in. from the floor is a 3- to 5-in. band of bone which can be separated from the coal satisfactorily by no other means than cutting. Attempts have been made to mine the seam by pick and by undercutting but both schemes failed because the bone adheres tenaciously to the coal. The large-diameter cable indicates that alternating current is used for cutting.



cutting a kerf in coal. It applies in lesser degree where the machine cuts in bone, and not at all where the cutting is in slate. In the latter case, cutting really serves as a measure of safety because of the slate bug dust produced. Sprinkling the cut with water taken from a pipe line or from a storage tank by an arrangement such as that described in *Coal Age*, May 14, p. 711, will prevent a dangerous quantity of dust from floating in the air. Respirators may be worn by the crew for protection against the shale dust coming from the kerf, as in the Elsie No. 2 mine where respirators are used by the crews. Electrically the top cutters are as safe as the undercutters, it being possible, of course, to procure permissible equipment in either machine.

## Canada Has Much Semi-Anthracite in Alberta Reserve Beds

The Dominion Fuel Board has issued a report by James McEvoy, of the Canadian Geological Survey, on the coal areas of the Smoky River and Sheep River district in Alberta, of which Mr. McEvoy made a close examination. These coal areas are interesting but not commercially available yet. He states that there is no anthracite in these areas. In one locality on Smoky River there is coal the analysis of which shows a fuel ratio just within the semi-anthracite class, but physically it has no anthracitic properties. A large area on Smoky River and Sheep River contains semi-bituminous coal, or as it is usually called in the West, "high grade" bituminous. Considered as a new source of coal supply the principal fact is the occurrence of a large tonnage of high grade bituminous coal, one notable 14-ft. seam grading in places by analysis as semi-anthracite.

This seam will give a superior steam coal, but it is not notably better than the other high grade bituminous coals already developed in Alberta in the qualities which domestic users require. None of these coals will satisfy the domestic consumer who wants fuel to take the place of anthracite as they all have a ragged fracture which makes fine dust when handled and they will cause a deposit of soot in flues and chimneys. While Mr. McEvoy regards these areas as a valuable asset in the future, he considers that there is no need for their development on a commercial scale for many years to come.

**Blue Diamond Mine, One of the Largest Producers in the Hazard Field**

At the left is the coal loading tipple and aerial refuse conveyor of the Blue Diamond Coal Co., Blue Diamond, Ky. This mine loads 2,500 tons per day. Flight conveyors retard the coal on its movement down the hillsides from the mine openings on each side of the hollow. On the right is shown the repair shop and substation on the "Old Side" of the Blue Diamond mine, which is one of the leading producers in the Hazard Field. This shop, supervised by Harry Kivett, chief electrician, does repair work for the mines of the Sapphire and Liberty Coal companies which are under the same management as the Blue Diamond.

# Illinois' Hope Lies in Mechanical Loading and Cleaning, Speakers Tell Institute

**By Frank F. Tirre**
St. Louis, Mo.

ILLINOIS' HOPE of regaining its position in the the coal industry in spite of non-union competition lies in reducing its production costs by mechanical loading. To accomplish this it will be necessary for union opposition to be softened and for coal cleaning methods to be adopted generally, speakers insisted at the thirteenth meeting of the Illinois Mining Institute Nov. 6 and 7 at West Frankfort, in the heart of the southern Illinois coal field. The two-days' meeting gave opportunity for much good fellowship at the Franklin County Country Club, a technical session, visits at various mines, a dinner in honor of A. D. Lewis, the newly appointed director of the Illinois Department of Mines and Minerals, and an election of officers in which E. G. Lewis of Royalton, Ill., was chosen president for the coming year.

Under the guidance of "Jack" Rodenbush, mine superintendent for the Chicago, Wilmington & Franklin Coal Co., the visitors were taken down into Orient No. 2 mine, the present holder of the world's tonnage record, 11,325 tons in 8 hr., made on Nov. 4. On the day of the visit 6,000 tons were produced up to the noon hour without confusion or interruptions of any sort. Other visitors made a general inspection of the district, including strip mines, and many accompanied John E. Jones, rock dusting authority, on his safety inspection tour through Old Ben Coal Corporation mines. The fact that this was the "thirteenth" meeting of the Institute was no "hoodoo" as the gathering was a large and interesting one.

### Elect E. G. Lewis President

Harvey E. Smith, retiring president, in his opening remarks spoke sadly of the recent death of Martin Bolt, former secretary-treasury of the Institute and director of the Illinois Department of Mines and Minerals. After some routine matters were disposed of the constitution was changed to provide for twelve members of the board of directors instead of five, and after the report of D. D. Wilcox, chairman of the nominating committee, had been read the following officers were elected: President, E. G. Lewis, Royalton, Ill.; first vice-president, Wm. Kidd, Peoria, Ill.; second vice-president, Dr. L. E. Young, St. Louis, Mo.; secretary-treasurer, Frank F. Tirre, St. Louis, Mo. The executive board consists of the following: Thomas Back, Jas. S. Anderson, J. A. Garcia, J. A. Jefferis, John E. Jones, F. F. Jorgensen, S. T. Jenkins, A. D. Lewis, Geo. McFadden, A. C. Callen, John Rodenbush and Ed. Coulehan.

The subject of machine loading was introduced with John A. Garcia in charge of the discussion. Mr. Garcia pointed out that the selection of the machine with which to load coal was not all that was necessary. The idea must be sold to the whole organization in a mining company.

"Many coal operators have persisted in the old method of doing this work as we used to do it 50 years ago," said Mr. Garcia, "Mechanization of coal mines is at our door. Are we going to open the door or are we going to let this opportunity, which does not knock more than once, pass on? We are confronted with competition from other states whose favorable mining rates are enabling them to take our markets. This has put our industry in Illinois in a most deplorable state and in my judgment the crisis can be met only with mechanization of our mines. This southern Illinois field with its thick seam and good coal is well equipped to meet competition."

### Useless to Look for Reduction

It was pointed out by a number of speakers that it is useless to expect a reduction in the present Illinois mining rate. A complete new order of producing coal must be made if the state is to maintain itself. Many changes will be noted during the next five years, especially in the cleaning of mechanically loaded coal. This is an item of cost ranging from 3c. to 10c. per ton. It seems prohibitive until one realizes that by mechanization five times this amount can be saved. Mechanical loading will increase the quantity of impurities 1½ per cent to 3 per cent, and in some instances it may be necessary to wash the coal. A washing method was mentioned which cleans by stratification at a cost estimated at 6c. per ton as against a cost of 25c. per ton on a jig washer. With this washer there is no loss of water. It is reused.

Most southern Illinois coal smaller than 3-in. must be washed, speakers declared. Larger coal, machine loaded, can be picked as clean as if it were loaded by hand. Machine production averaged 264 tons per shift per loading machine in one mine on room work only, making a saving of 50c. per ton. Several speakers agreed that proper coal cleaning should not absorb more than 20 per cent of a loading machine's savings.

It was suggested by a prominent engineer that in the installation of mechanical methods of producing coal, only a part of the mine be equipped with loaders at first. A careful record could be kept of the earnings and these earnings applied to the further purchase of machine loaders until hand loading was completely displaced.

### Machines Quickly Repay Investors

Machine loading reduces the number of men in a mine and cuts down by 60 per cent the number of working places required under hand-loading. Concentration of the working force such as this reduces the length of entry to be kept up, and the investment for rails, wire, and supplies. It was estimated that in a period of three years a mine can be fully equipped with machine loaders bought with the earnings of those first installed.

In some instances a machine cuts and loads the coal. Where this is done, shooting during the day with men in the mine is necessary. This is now considered by some to be in violation of the law. The Institute urges a speedy solution of this question.

In Illinois a joint commission of miners and operators has been appointed to work out a scale of wages for men operating loading machines. The Institute is appealing for an immediate report from this commission because further installation of loading machines in Illinois is blocked by order of the United Mine Workers, District 12, until a scale is provided.

Dr. F. C. Honnold, of the Honnold Coal Bureau in Chicago, acted as toastmaster at a dinner in honor of the new director of the Illinois Department of Mines and Minerals, A. D. Lewis, a brother of John L. Lewis, International President of the United Mine Workers.

The first speaker was T. C. Powell, president of the Chicago & Eastern Illinois Ry., who spoke about the part played by the railroads in the production of coal in this country. He congratulated the southern Illinois field upon the opportunity it has before it as the greatest coal-producing center in the world, and deplored the present competition it has to meet—a competition that is causing many of the large producers to remain idle when they ought to be in operation.

"In looking over figures," said Mr. Powell, "I find that we have 70 mines on the line of the C. & E. I. Out of the 70 operations, 37 are definitely closed. These 37 have a rated capacity of 1,036 cars per day.

### CITES RECORD FOR OCTOBER

"Our actual experience during October was, however, that of 33 mines in condition to operate, the fluctuation from day to day has been extreme in that only twelve mines were working on Oct. 12, and on only one day were as many as 28 mines in operation. The average for the month was about 20 mines. Instead of turning out 1,330 cars of coal per day, the volume fluctuated between 300 and 400 cars with the maximum never reached.

"Even the reduced quantity of coal that has been loaded has not all been sold. We have on hand today unbilled something like 400 cars of coal. Each railroad interested in the development of its coal mines must make a heavy investment in coal cars and as long as those cars are idle or stand under load unbilled, and all during the period that they are moving back to the mines for loading, interest charges on the cars continue to accrue. A coal car which costs $2,500 and will hold 70 tons of coal, must make at least 40 trips under load before the cost of the car has been made, to say nothing of the cost of transportation, maintenance and interest charges in the meantime. It is to the interest of the coal companies as well as the railroads to move these cars quickly between the mines and the consignee. The more quickly the cars are released by the consignee the more certain the mines will be of getting sufficient equipment for additional business.

### POINTS TO FAILURE OF WATERWAYS

"There has been some talk of waterways, especially in this part of the state. If any means can be found to cheapen the transportation of coal by water ways, I would say 'Amen' as I believe that the public is entitled to all such improvements that are feasible. But before our government or state is called upon to make so vast an expenditure as has been proposed, I would want you to look well into the situation, gathering information as to the experience of the C. & O. canal into Washington. I believe it has been a failure. In New York the Erie canal was constructed between 1905 and 1924 and a sum of $260,000,000 expended, and it is still unfinished. The people of New York State pay an average of $4.40 for every ton handled by this canal, and the only commodities handled are a little bit of gravel, sand, oil and grain. These two examples should make tax payers consider."

Harvey E. Smith, past-president of the Institute made a graceful address complimentary to Mr. Lewis, the new state director of mines and banquet guest of honor. He also extolled the virtues of the Institute.

### SHOWS CROSS-SECTION OF MINING INTERESTS

"Membership in the Illinois Mining Institute is open to those either engaged in or interested in mining," said he, "and its roll of members shows a true cross-section of the mining interests of the state. Included in its members and present at this meeting are the owners and officers of coal properties, general managers and general superintendents, pit bosses and assistants, mine examiners and top bosses, electricians and mechanics, consulting engineers, state mine inspectors, rescue men, representatives of the United States Bureau of Mines, mining engineers and geologists, college professors, railroad men, officials of the United Mine Workers, coal salesmen, salesmen selling equipment and supplies necessary to the operation of the mines, electrical engineers representing the public utilities which supply the mines with power, and, last but decidedly not least, the miners—the men who really produce the coal and who are the foundation upon which the whole structure of coal production rests.

"This Institute has in these lean years of the coal business even a greater field for service than was presented in the more prosperous years. We mining men of Illinois, even though the outlook for the immediate future is dark indeed, will not admit that the coal production of this state is to fall permanently from the record of nearly 90,000,000 tons a year to less than half that figure. We are favored in this state with coal deposits which in extent and in favorable mining conditions are second to none. With these natural riches at our command we will not admit that we are not able to devise means and methods by which this coal may be extracted so as to compete with coals from other states. The best brains of the industry have been working on this problem without as yet finding a solution, but the problem must and will be solved.

### CO-OPERATION WILL HELP SOLVE PROBLEMS

"The solution, however, will only come through the thorough co-operation of all the various interests connected with the industry. In arranging this meeting in the heart of the coal producing center of the state, affording this opportunity for the free interchange of ideas, it was with the hope that some constructive thought might be brought to light which would assist in clearing the industry's troubles which so vitally affect us all."

Dr. Honnold next called upon H. C. Miller of the Bureau of Mines, who assured the new state director of the hearty co-operation of that governmental bureau. Dr. L. E. Young spoke in behalf of the operators of the state, extending his most hearty good wishes and pledging the support of Illinois mine owners. State Senator F. C. Sneed, welcomed Mr. Lewis on behalf of the United Mine Workers, District 12, after which the honor guest made fitting reply, thus bringing the Institute's semi-annual meeting to a close.

# Miners' Union Maintains Doubtful Hold on Far West and Mountain States

**By Sydney A. Hale**
Special Contributor, *Coal Age*,
New York City

THE LABOR SITUATION in the bituminous coal producing states west and north of the area covered by the operations in the Southwestern Interstate Field on the whole has shown less change in recent years than any other part of the country outside of the strongly unionized districts of Illinois, Indiana, Iowa, Michigan, Kansas and Missouri. To this generalization, however, three striking exceptions must be made. Colorado has been in more or less turmoil for over two decades. A large part of the operations in Washington—the only important producing state on the Pacific slope—has broken away from the union and North Dakota has established an open-shop basis. In the other states in the Rocky Mountain and Pacific divisions, the balance of power between union and non-union fields struck several years ago remains unchanged.

The United Mine Workers established itself in the Northwest in the early years of the present century. Montana and Wyoming were organized in 1904, Washington came into the fold in 1905; full recognition was extended to the union in 1908. In general, the effect of that recognition has been the same as in the older organized territories farther east. Basic day rates, of course, have been controlled by the advances granted in the Central Competitive Field. These advances, it will be recalled, raised the level of the base inside day rates from $2.84 under the 1912-14 contract to $7.50 under the Jacksonville agreement. Pick-mining rates in Montana and Wyoming were increased a total of 42 to 43.5c. per ton during the same period. These advances were more than met in the non-union and open-shop mines of Colorado and Utah, where the net increases for typical groups of operations ranged from 40 to 52c. per ton.

Individual variations both in basic rates and in increases, however, were much greater at the unorganized mines. A study of wage rates, made by the United States Coal Commission, showed increases ranging from 8 to 64c. per ton at 32 mines in Colorado and 16 to 48c. per ton at nine mines in Utah. In the majority of cases, the hourly rate for typical inside labor, such as brakemen, drivers and trackmen, was slightly lower in Colorado in the spring of 1912 than it was in the Central Competitive Field. In that major group the base rate was 35.5c. per hour. A few mines paid a higher hourly rate in Colorado at that time, going as high as 40c. but in most cases the rate was between 31 and 31.5c. Rates were advanced generally in 1912 and 1913 and cut at many operations in Colorado in the second half of 1915. Advances were common in 1916 and 1917, the second half of 1919 and in 1920. Reductions were made in the second half of 1921 and in the first half of 1922, but rates were restored during the second half of 1922 so that Jan. 1 1923 found the general average a few cents per hour above the base rates in the Central Competitive Field.

This summary and the detailed figures presented in Table VI illustrate sharply the effect of organization upon the adjacent non-union states in the Mountain division. Although changes have been more frequent in the unorganized states of Colorado and Utah, it hardly can be denied that the proximity of the strongly organized union fields of Montana and Wyoming has had a stabilizing influence upon non-union rates—particularly in times of prosperity. Wartime and post-wartime increases in the organized fields have been matched by increases in the open-shop regions, but the actual changes in cents per ton or per day have not always been the same. The non-union districts, however, have been in a position to take advantage of depressed conditions with wage reductions.

This was notably true of Colorado in the first half of 1922, when the pick-mining rates were reduced to a 1917 basis. The 1920 rates, however, were promptly restored the last half of the year. At the present time, the controlling rates are substantially less than the 1920 bases. In other words, it appears to be the fixed policy in that state to give the non-union workers the benefit of any wage victory won by the United Mine Workers.

*Advances in Montana and Wyoming took place in April, October and November, 1917 and in November, 1919.

---

Fifth of a series of articles describing the changes in the labor status of the different bituminous coal producing districts of the United States in recent years. Preceding articles appeared in *Coal Age*, Sept. 25, Oct. 1, 8 and 29. Another article will appear in an early issue.

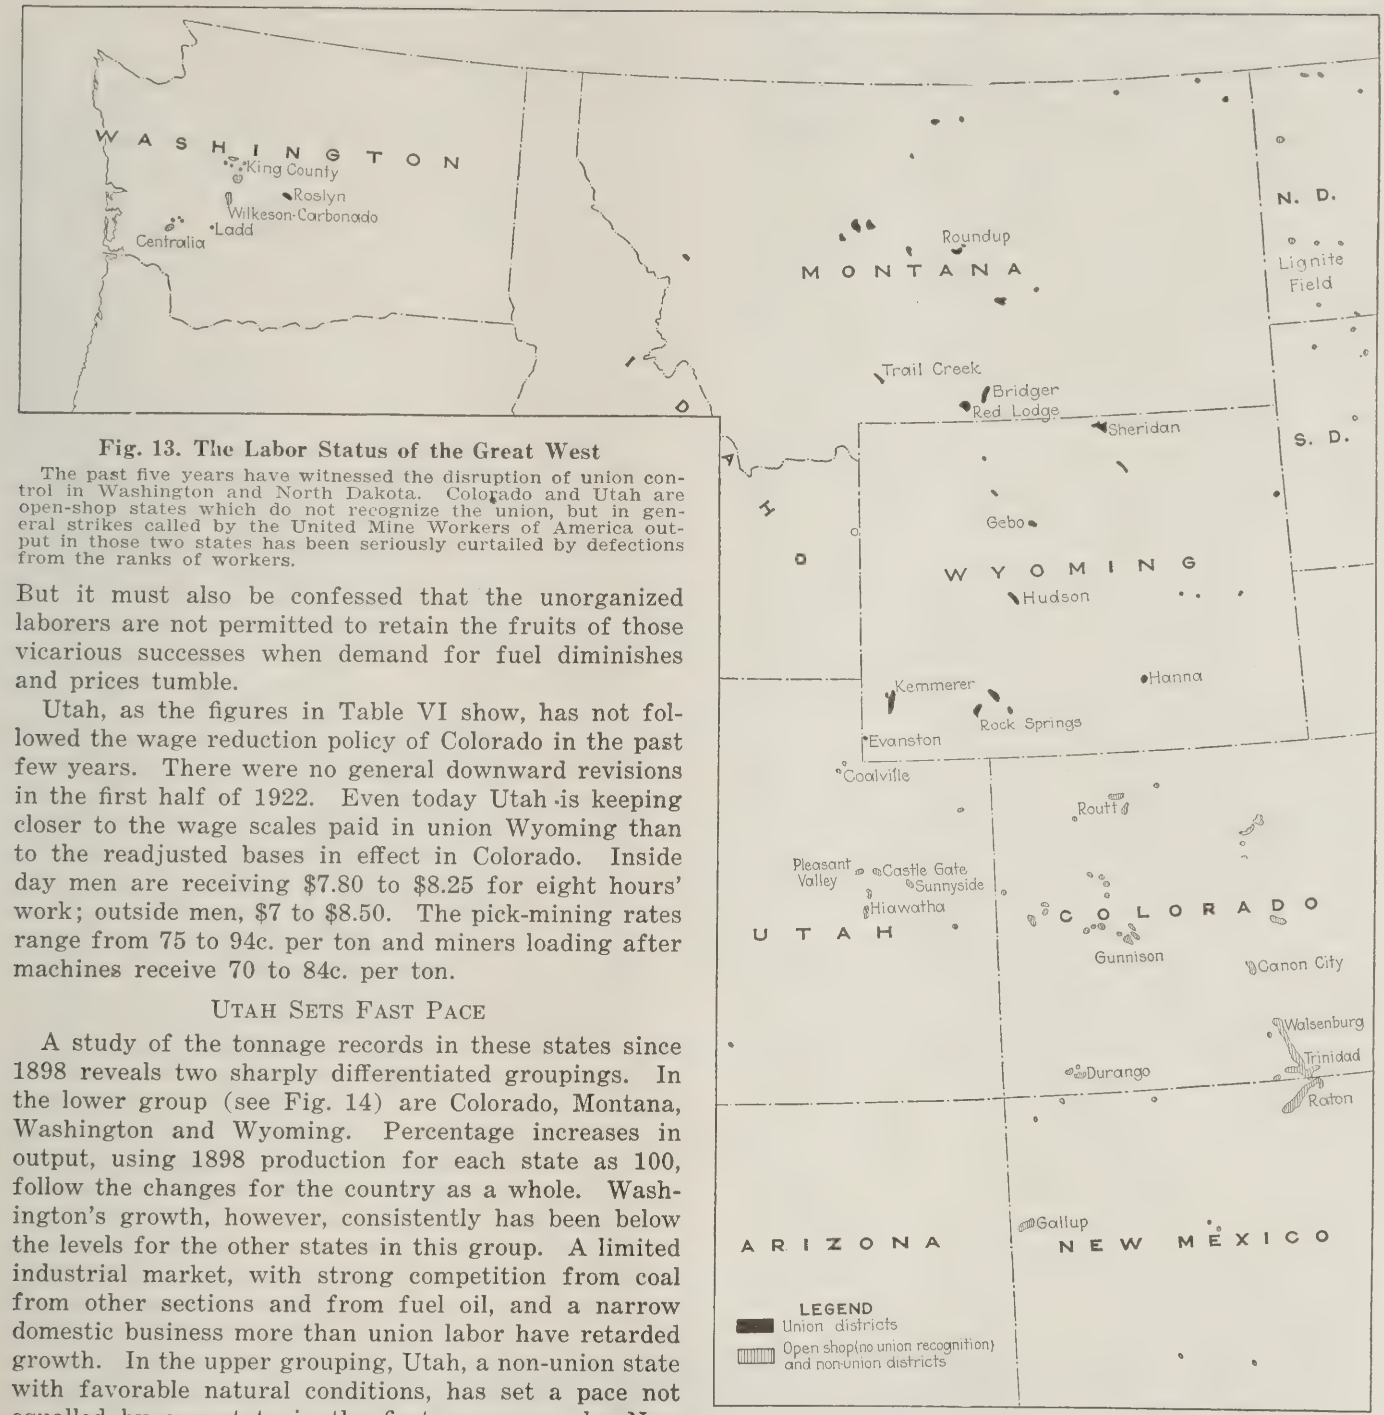

**Fig. 13. The Labor Status of the Great West**

The past five years have witnessed the disruption of union control in Washington and North Dakota. Colorado and Utah are open-shop states which do not recognize the union, but in general strikes called by the United Mine Workers of America output in those two states has been seriously curtailed by defections from the ranks of workers.

But it must also be confessed that the unorganized laborers are not permitted to retain the fruits of those vicarious successes when demand for fuel diminishes and prices tumble.

Utah, as the figures in Table VI show, has not followed the wage reduction policy of Colorado in the past few years. There were no general downward revisions in the first half of 1922. Even today Utah is keeping closer to the wage scales paid in union Wyoming than to the readjusted bases in effect in Colorado. Inside day men are receiving $7.80 to $8.25 for eight hours' work; outside men, $7 to $8.50. The pick-mining rates range from 75 to 94c. per ton and miners loading after machines receive 70 to 84c. per ton.

### UTAH SETS FAST PACE

A study of the tonnage records in these states since 1898 reveals two sharply differentiated groupings. In the lower group (see Fig. 14) are Colorado, Montana, Washington and Wyoming. Percentage increases in output, using 1898 production for each state as 100, follow the changes for the country as a whole. Washington's growth, however, consistently has been below the levels for the other states in this group. A limited industrial market, with strong competition from coal from other sections and from fuel oil, and a narrow domestic business more than union labor have retarded growth. In the upper grouping, Utah, a non-union state with favorable natural conditions, has set a pace not equalled by any state in the first group nor by New Mexico. On a flat tonnage basis, however, Utah output is still far below that of Colorado and lags considerably behind that of Wyoming. North Dakota, not shown, has registered a still greater percentage gain, but the actual tonnage raised is relatively small.

The labor situation in Colorado has been more in the limelight, but to Washington belongs the distinction of making the first clean-cut, and successful, break with the union since the war. On March 1, 1921, a committee representing 90 per cent of the commercial (non-railroad) tonnage of the state announced that it was no longer possible to continue to pay the 1920 wage scale and proposed an average reduction of 23 per cent, to be effective two weeks later. If the district officials of the United Mine Workers, with whom the operators had been in fruitless negotiation for two months, would not assent to the plan, the mines would close down.

The miners rejected the reduction and the middle of March saw all but one company on the west side of the Cascades idle and one large company and several smaller ones on the east side down. The railroad mines in the Rosyln-Cle Elum field, however, continued to operate without reduction in wages; most of the mines in that section shipping coal commercially also continued to work. To the charge that the action of the operators closed down constituted a lockout in violation of existing agreements, the producers accused retorted that they had put the 1920 rates in effect following the decision of the United States Bituminous Coal Commission in the Central Competitive Field, but had refused to enter into any written contract guaranteeing the maintenance of those wages. Without the reduction sought, declared the operators, it would be impossible to meet the competition of Vancouver Island and Utah coal and of fuel oil.

The final severance of union relations did not come until midsummer. In the interim operators had consented to the appointment of a quasi-govermental commission to investigate the situation and later had stated their willingness to accept a wage scale recommended by an official of the state labor department as the result of that investigation. The union, however, after several weeks' delay, refused to consider the proposed scale or any other suggestion involving a reduction in wages. Thereupon the operators issued notice that they would no longer recognize the union and stated that they would reopen their mines at the scale suggested by the neutral member of the investigating commission. This scale called for a rate of $5.25 to $6 to inside underground labor and $4.50 to common labor above ground. Open-shop operation was formally commenced Aug. 22, but it was several weeks later before the producers were able to augment the state's production to a material degree, and union opposition did not completely disappear until the middle of 1923.

### Two Counties Remain Union

Throughout this quiet struggle Kittitas and Thurston counties have remained steadfastly union. Production in those two counties is dominated by railroad-controlled coal companies, and such operations, generally speaking, have been particularly susceptible to union advances and most unwilling to invite a shutdown or serious curtailment of output by questioning union authority. There are only three operating companies in Thurston County: one, railroad controlled, produced 174,403 tons out of the 194,702 tons mined in that county in 1922 and 252,032 tons out of 268,202 tons in 1923. In Kittitas County, 866,183 tons out of a total of 1,053,584 tons in 1922 and 1,119,102 tons out of 1,358,359 tons in 1923 were produced by a railroad coal company—one of the six operators in that county.

The record of non-union and union production for the state as a whole during the past three years has been as follows:

| | Union Mines Net Tons | Non-Union Mines Net Tons |
|---|---|---|
| 1922 | 1,248,246 | 1,352,722 |
| 1923 | 1,626,561 | 1,319,446 |
| 1924 | 1,339,490 | 1,315,425 |

Approximately 2,045 men are employed in the union and 2,261 workers in the non-union mines.

Kittitas and Thurston counties still recognize the union, but the losses the United Mine Workers has suffered in the rest of the state have left their mark on the union wage scales. Up to May 1, 1923, the union maintained its "no backward step" policy in Washington as uncompromisingly as it had in other parts of its realm. But, after a month's suspension and two months' squabbling, district union officials did agree to a reduction in day rates—not to the level of non-union rates, it is true, but substantially less than had been paid. A comparison of the rates carried in the three scales is shown in Table VII.

Organized labor in the coal fields of Colorado has had a checkered career. For over 40 years it has struggled to establish itself in that state, only to go down in defeat when it pressed for recognition. There were strikes in 1883, 1893, 1903 and 1913 to establish union power. Strong-arm methods against the union were resorted to in some of these struggles. Organizers and members of the national executive board, said the convention of the United Mine Workers in 1905, "were murderously assaulted in broad daylight while traveling on passenger trains; other organizers were held up and beaten on the public streets, while still others were threatened that, if they did not depart from Colorado, their lives would be in danger." And in 1914 there was Ludlow!

Out of this bitter and bloody industrial warfare came the law creating the Colorado Industrial Commission and the establishment of the Rockefeller Industrial Representation Plan at the mines of the Colorado Fuel & Iron Co., the largest operator in the state. The Industrial Commission law, passed in the spring of 1915, "requires that no change in wages or hours shall be made without 30 days' notice to the commission. If a strike or lockout results from the change, or the

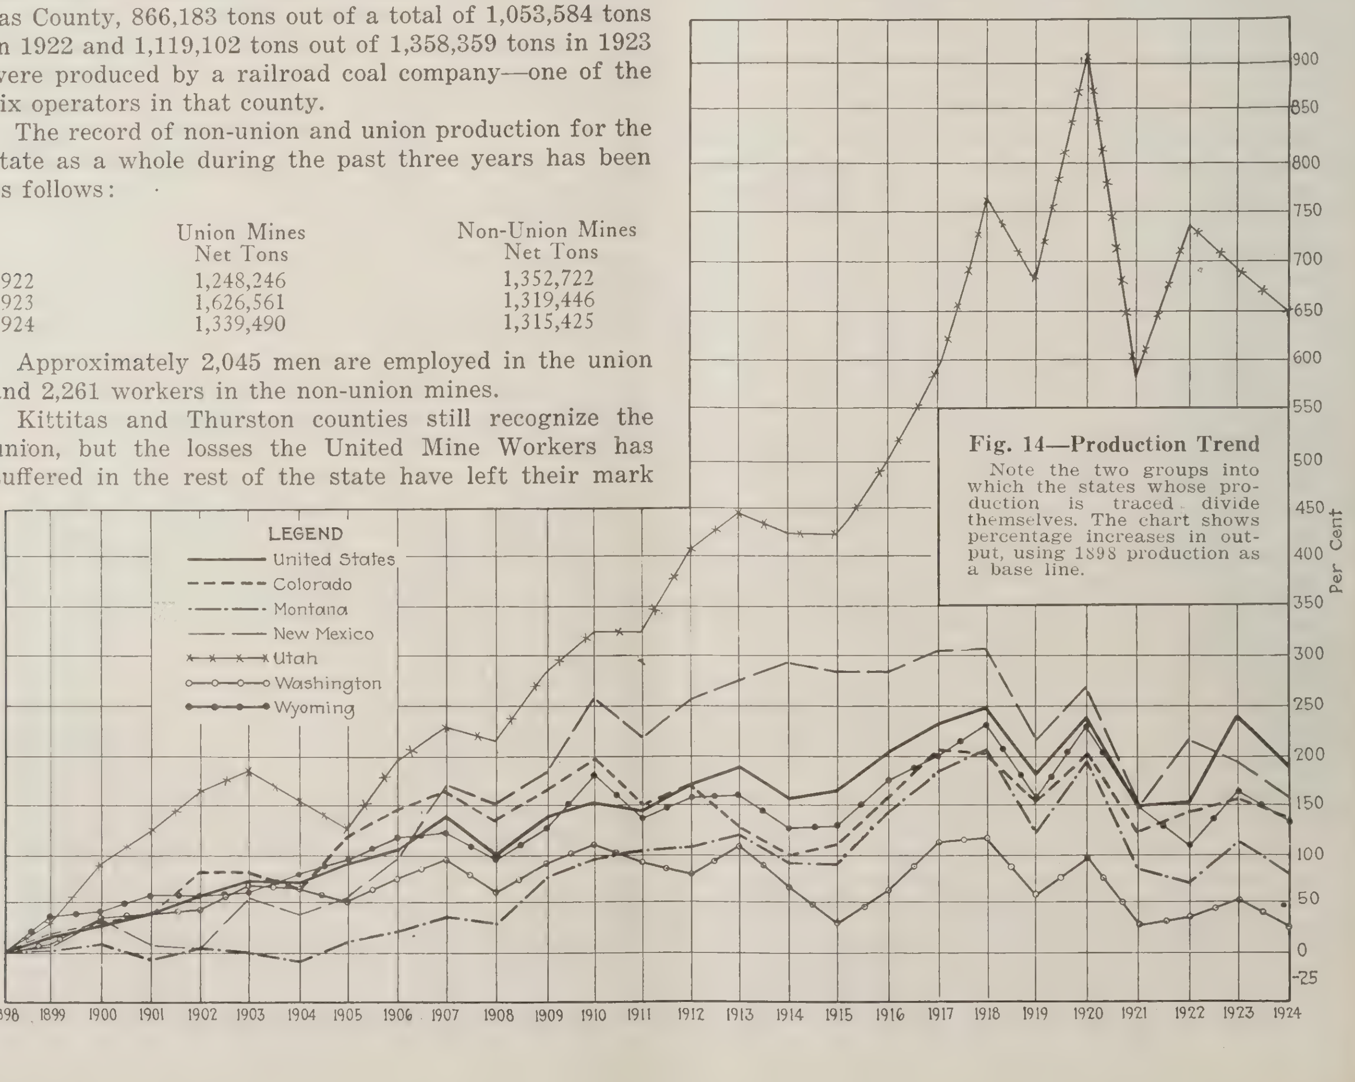

**Fig. 14—Production Trend**

Note the two groups into which the states whose production is traced divide themselves. The chart shows percentage increases in output, using 1898 production as a base line.

### Table VII—Day Wage Scales in Washington

| Inside Labor | Union Mines Prior to April 1, 1923 | Union Mines Effective May 1, 1923 | Non-union Mines 1923 |
|---|---|---|---|
| Miners, timbermen, tracklayers | $8.25 | $7.50 | $6.00 |
| Shot-lighters | 8.25 | 7.50 | ..... |
| Timbermen's helpers, tracklayers' helpers, hoist-men on development work, cagers' helpers, pumpmen, inside day labor not otherwise specified | 7.55 | 6.00 | 5.25 |
| Motormen, rope-riders, cagers | 7.75 | 6.25 | 5.50 |
| Drivers | 7.75 | 6.25 | 5.25 |
| Parting boys | 4.82<br>5.32 | 3.50<br>4.00 | .....<br>..... |
| Greasers | 4.77 | 3.50 | ..... |
| Trappers | 4.52 | 3.25 | 3.25 |
| Hoist boys on development work | 5.42 | 4.25 | ..... |
| Locomotive engineers | 7.75 | ..... | 5.50 |
| **Outside Labor** | | | |
| Engineers | 8.00 | 6.50 | 6.00 |
| Firemen, washermen (first class) | 7.40 | 5.90 | 5.25 |
| Cagers, development engineers | 7.50 | 6.00 | 5.25 |
| Cagers' helpers | 7.10 | 5.50 | 5.00 |
| Dumpers | 7.10 | 5.60 | 5.00 |
| Teamsters, blacksmiths' helpers | 7.25 | 5.50 | 5.00 |
| Couplers | 4.52 | 3.25 | 3.25 |

| Blacksmiths (first class) | 8.05 | 7.00 | 6.00 |
| Blacksmiths (second class) | 7.75 | 6.25 | 5.50 |
| Carpenters (first class) | 8.05 | 7.00 | 5.75 |
| Carpenters (second class), bunker machinery tenders | 7.55 | 6.00 | 5.25 |
| Car repairers, choppers | 7.25 | 5.75 | 5.00 |
| Screen men, moving picking table men | 6.75 | 5.00 | 4.50 |
| Screen boys, moving picking table boys | 4.72 | 3.50 | 3.50 |
| Outside labor not otherwise specified | 7.00 | 5.00 | 4.50 |
| Machinists (first class) | 8.05 | 6.75 | 6.00 |
| Machinists (second class) | 7.75 | 6.00 | 5.50 |
| Lamp men (first class) | 7.55 | 5.75 | 5.25 |
| Lamp men (second class) | 7.00 | 5.25 | 4.75 |
| Washermen (second class) | 7.20 | 5.70 | 5.00 |
| Jig and table tenders | 7.00 | 5.50 | 4.75 |

proposal of it, the commission has power to order that former conditions be restored until an investigation can be made and a decision rendered."

This is not the place to describe and study the workings of the Industrial Commission law or of the Rockefeller plan. That latter was designed to effect a permanent peace in the relations between the coal company and its workers without yielding to the United Mine Workers "by developing some organization in the mining camps which will assure to the employees the opportunity for collective bargaining, for easy and constant conferences with reference to any matter or grievance which may come up and any other advantages which may be derived from membership in the union." The plan, which did not recognize the United Mine Workers, but which did not prohibit proselyting for individual members by union agents, is mentioned because its adoption led to an unexpected result—a union contract and recognition by the Victor-American Fuel Co. and 16 other Colorado operators.

In justifying its action, the Victor-American company asserted that the Colorado Fuel & Iron Co., by adopting the Rockefeller plan, had "opened the door to the unrestricted activities of the organizers of the United Mine Workers of America" and declared that self-protection under war conditions (the contract was signed in March, 1917) made the action taken by the Victor-American and its associates necessary. The agreement expired March 31, 1920, and was not renewed. The insurgent operators were willing to be guided by wage rates in competing union fields, but declined to continue recognition of the labor organization. Possibly the general strikes in 1919 and 1922 and the failure of the 1917 agreement to stampede the Colorado Fuel & Iron Co. and other operators not parties to the 1917 contract into recognition of the United Mine Workers soured the signatories.

Since the expiration of that agreement and the unsuccessful strike of the miners in the northern lignite fields to force recognition, union organization activities have been conducted more or less under cover. Yet it should not be forgotten that more than 50 per cent of the productive capacity of the state was hit by the 1922 strike. Recently the union has become more open in its efforts to strengthen its organization and to swell its membership. In this campaign it is placing great stress on the manner in which Colorado operators have departed from the Jacksonville scale.

The disintegration of union power in North Dakota was completed last year, when the last two mines which had been giving it recognition abandoned the cause of the United Mine Workers. At the present time there is no well-defined wage scale in effect in that state. Rates range from 65c. to $1 for room work and 75c. to $1.25 for entry work. The significance of North Dakota lies not in the tonnage being raised, although the output during recent periods of scarcity has been increased ten- and fifteenfold over the 1898 base. This growth means that the state is becoming more and more self-sustaining in its coal supply, thereby blocking the expansion Montana and Wyoming might expect from cultivating North Dakota markets.

In the Far West, as in the Southwest and in the Central Competitive Field, the changes in labor status which have taken place since the war all have been unfavorable to the United Mine Workers of America.

**Scenes at the Black Star Coal Co., Inc., at Alva, Ky.**

The illustration above shows the tipple of the Black Star Coal Co., Inc., at the company's mine in the Harlan Field, at Alva, Ky. On the right is a storage-battery locomotive bringing up a loaded trip to the tipple. The headlights shine through the bumper.

# Beating Anthracite Is Difficult in Winnipeg

**By George R. Pratt**
Alberta Government Fuel Engineer,
Winnipeg, Man.

FOR SEVERAL YEARS a consistent effort has been made to enable the producers of various coals in Alberta, Can., to gain and hold for their product the extensive market in and around Winnipeg in Manitoba which has been enjoyed for so long by Pennsylvania anthracite and other American coals. This campaign has progressed through many stages with varying degrees of success. There have been many obstacles to surmount, some of which have been overcome so that today the outlook is hopeful.

Winnipeg is situated far inland and, in consequence, has a long and continuous winter, without break, and a dry atmosphere. Until 1918 practically all domestic heating was confined to the use of United States anthracite.

What happened to change this? First a shortage occurred, due to a strike of anthracite miners. This was followed by a lowering of quality, a price boost considerably above its value, and a suggestion from the United States that Canada was not entitled to all the anthracite she desired because she had so much coal of her own.

It required all of these adverse conditions to convince the Alberta coal producers at the time that there was a market for their coals in Winnipeg, and this was realized by them so suddenly that they immediately began to ship coals of all descriptions, regardless of the particular use of each coal or of its adaptability to the market. At the end of the season it was found that the phophesied disasters, from the use of Alberta coal, had not materialized.

However, new difficulties arose. Many citizens were satisfied that they did not want to be bothered with Alberta coals. The reasons given were: They were too dirty to put in the house; there was too much trouble in firing; the coals were too sooty and smoky; some coals burned too quickly and the fire went out, others burned too slow and gave no heat; some coals clinkered too much, others made too much dusty ash; a particular furnace was not suitable, other furnaces were too large or too small. Some of these objections were excuses, others were valid reasons from the standpoint of the consumer. Much of the trouble arose from the opinion that the use of Alberta coal was only a temporary measure. Also, the old coal dealers had established connections with producers in the United States and it meant loss of business to introduce Alberta coals when they stood no better chance of selling these coals than had a new coal dealer.

Opposed to the viewpoint of the majority was a minority of citizens who had had satisfactory experience in using Alberta coals in the ordinary furnace equipment, and as a result were prepared to continue its use. From these conflicting experiences there arose the realization that there was a permanent market for Alberta coals *if* the public could be educated in their proper use—to buy for service instead of at a price.

### WAY OF SUBSTITUTER IS HARD

IN VARIOUS parts of the United States efforts are now being made to substitute something for anthracite in the esteem—and coal bins—of householders. The effort is not new. In Manitoba and Alberta the campaign to substitute Canadian coal for Pennsylvania hard coal and for some other kinds of American coal has been going on for five years. The obstacles which must be overcome by the substituters are many. Mr. Pratt in this article describes some of them. After all, it is a tough job to wean the people of a whole geographical division away from *any* fuel to which they have become accustomed.

During the following season some new friends of Alberta coals were made, and some were lost. The losses were mostly due to the lack of standardizing the fuels, and also to the fact that *all* coals were offered as Alberta coals. Considering the wide range of varieties offered, few customers could guess right every time in their selection. That season, one of the larger Winnipeg dealers maintained a demonstration showing how the different fuels should be burned in various equipments and by that means made hundreds of friends for Alberta coal. The results obtained by this firm convinced the Alberta government that the education of the consumer was essential for the building of a permanent market.

The first effort was the establishment of practical demonstrations to instruct the coal user how to get the best service from the fuel. This was accomplished by setting up several domestic furnaces and operating them in the office in Winnipeg. It was discovered that most of the visitors to our demonstrations were friendly to Alberta coal, and it was the others, who did not come, that we had to get in touch with.

To reach these people newspaper advertising was started, and we published stories of general interest about coal, under the title of "Coal Truths." We had depended upon holding these new customers, until they had become used to the coal, by appealing to their patriotism and by enlarging upon the national profit in using only Canadian coals. In this we were disappointed and found that it required considerable logic to persuade a person, on sentimental grounds, to use a coal which he considered was costing him more than it should.

This experience convinced us that simply teaching people how to use Alberta coal would not hold a permanent market for it and that our main efforts should be directed toward preaching and proving economy by its use. We, therefore, continued our experiments in order to establish standard instructions for the economical

---

This article is from a paper read by Mr. Pratt at the annual western meeting of the Canadian Institute of Mining and Metallurgy, Winnipeg, Man., Nov. 4, 1925.

burning of Alberta coal, and these instructions were published in book form in 1923.

While these methods have met with some success there is a feeling that it is the duty of the Dominion Government to adopt means whereby the sale of Canadian coal may be increased, and that measures to this end should be incorporated in a national policy of solving Canada's fuel problem.

Unfortunately, intensive competition from mines, importers, wholesalers and retailers had developed a condition that resulted in the establishment of over 200 registered coal dealers in the city of Winnipeg. Profitable business for Alberta coal was therefore difficult because a large percentage of coal was distributed by men who were not competent to give the necessary information about burning the fuel—so essential for retaining a market.

### Originally Sold as Soft Coal

All Alberta coals, when first entering the Winnipeg market, were sold as Alberta soft coal. Because of the confusion that this made the steam-coal mines sold coal under names that each had established for its particular product and domestic coals were again sub-divided and each coal was named after the district in which it was produced (there are now 35 districts in Alberta producing domestic coals).

It was quickly apparent that the grouping of several different coals under one district name was not satisfactory from the market point of view. Mines that had developed to the point of producing a good quality of fuel, by using proper equipment and skill in mining and preparation, were in competition with other mines, in the same district, that possessed little or no equipment and which were operated with little regard for the quality of the coal produced.

The best class of coal producer set the price according to his cost of production; the other man took advantage of this price when the market was in favor of the seller, but undercut the price when it was a buyer's market. As far as the buyer knew, or was concerned, both men were selling the same kind of coal. The variability in standards and price increased the difficulty of establishing a reliable market because the consumer could not be quaranteed value for his money at all times, nor had he means of protecting himself.

### Extend Mines Responsibility

While it may be desirable, from a market point of view, to limit the varieties of coal entering Winnipeg to the best in quality, according to price, it was not possible to do so without restraint of free trading. Therefore, it was decided that the next best thing to do would be to make the mine extend its responsibility, to value received by the consumer, and to establish trade marks by which its coal could be recognized.

This proposal was made to the Alberta government, and to the coal producers in Alberta, and resulted in the compulsory registration of every mine in Alberta and the adoption of trade names, under which all coal was required to be sold. A law to this effect was passed by the Alberta government during 1923 to operate for one year, but has since been made permanent.

The city of Winnipeg finally passed a by-law which defined a coal dealer and required coal delivery tickets to show the grade name of the mine and the district in which it was situated. This had the effect of establishing some evidence as to the kind of coal delivered, but as much coal is purchased from perusal of newspaper advertising, and irresponsible dealers continued to advertise "best coal" using district names and other generalities, it did not have the entire effect desired. The by-law was subsequently changed to include the advertising of trade names, but as it was not enforced, the disadvantage continued.

Included in the Winnipeg by-law was a provision which required the dealer to state the minimum calorific value of each coal he proposed to sell, and if any of his coals were below this minimum he was liable to prosecution. In theory this seemed a very desirable feature, but it actually worked to the disadvantage of all; the consumer, the regular dealer, and the coal producer.

As there are no official standards set for the calorific value of various coals it was left to each dealer to establish a value—which he had to live up to. The regular dealer set the value according to his experience with the coal which he had been handling, usually on coals fairly well established and of high quality. The irresponsible dealer set his calorific value sufficiently low so that it would permit him to sell the lowest grade of coal obtainable. It also permitted substitution.

On making representation to the Winnipeg authorities I was assured that the city would accept analyses made by the Alberta government. There being no suitable standards available a temporary list of coals was made and instructions were given to a testing laboratory to take 250 samples of coals, as received in Winnipeg, and to establish the desired standards. However, instead of improving the situation new problems arose which caused me to withdraw the temporary list of analyses.

### Prosecuted Several Dealers

Several dealers were prosecuted by the license department on the complaint that their coals did not meet the calorific standard that had been set. Two of these had an independent chemist to take samples of the loads. These samples showed the coal to be well above the established standards. The court dismissed the case.

The method of sampling adopted by the license inspector was the result of visual inspection. If he considered the coal to be below the standard he selected a small sample which he handed in for analysis. Those who understand the rudiments of sampling will appreciate that a person making a selection in such manner can pick just whatever he desires for the purpose in mind.

As it was made evident that the calorific value was all that the inspector looked for we withdrew our analyses. We had assumed that the calorific value would be used in conjunction with other characteristics in making a determination of quality.

The by-law is now under review with a view to its reconstruction so that it may operate as was originally intended.

In developing the market much advertising has been done, most of which has been of an educational nature; but if advertising has any value in obtaining markets for a product it also assists your competitor in taking your business away. Winnipeg is probably the most competitive coal market on the continent and it is essential that the Alberta producers should feel responsible for the economical handling of their coals if they wish to retain their hold on the domestic trade there.

# News Of the Industry

## Proposals for Emergency Rates Threaten Free-for-All Scramble For Eastern Domestic Coal Trade

Coal producing interests of West Virginia, eastern Kentucky, Maryland and Virginia clamored before the Interstate Commerce Commission last week for more favorable rate bases and routes into New England and the Middle Atlantic states. The low-volatile fields of the first named state, given an all-rail basis on lump, egg and nut sizes under the order of the Commission, suggested to Commissioner Campbell and Examiner Koch, before whom hearings were held in the rooms of the Merchants' Association, New York City, Nov. 12-14, that the rates should be extended to mine-run and slack during the present emergency and that other routes should be opened up if the bituminous fields were to take up the deficit in domestic supplies created by the anthracite strike.

At the tag-end of the sessions the Pittsburgh No. 8 field of Ohio came forward with an offer to shoulder some of the burdens of the East if the Commission would establish emergency rates from the mines in that district. The Virginia anthracite interests, who also desire to participate in this business, found the waiting for a chance to be heard too tiresome; when called upon to present their case, it was discovered that their spokesman had departed.

### Pennsylvania Makes Protest

Central and western Pennsylvania registered vigorous dissent to the proposals of West Virginia. Pennsylvania witnesses questioned the existence of the emergency pictured by the Commission and other witnesses. If the picture be true, they argued, authorization of long-haul movements would result in dilution of transportation facilities which would defeat the purpose for which new rates and routes were established. In this position they were strongly supported by counsel for the Pennsylvania and the Baltimore & Ohio railroads. Southern originating lines expressed a readiness to co-operate in any emergency measure adopted, although the Virginian thought that the recent decision requiring joint rates from the Winding Gulf field to the West was sufficient drain upon its equipment. The railroads will be given an opportunity to present their side of the case when the hearings are resumed at Washington, D. C., this morning.

For a time the New York hearings threatened to develop into a free-for-all scramble for a chance "to save New England" from freezing. Some of the enthusiasm went out, however, when Commissioner Johnston B. Campbell, after listening to railroad protests and conferring with his associates, announced:

"This hearing was brought about primarily to consider temporary rates and routes. Of course, the question of permanent rates and routes is before us, but I think I am safe in saying that we will confine our orders as the result of these particular hearings to the establishment of temporary rates and routes. Then, of course, the case can be kept open" for more leisurely consideration of future rates. The Commissioner intimated that the rates to be ordered following the New York and Washington hearings would carry a definite time limit.

Witnesses for the New England Governors' Fuel Committee and the industrial interests of the Northeast made the opening pleas for the establishment of rates on all sizes of low-volatile coal and for movement via all recognized gateways. The basis fixed in the Commission's order to destinations on lines other than the New Haven was criticized. Although it developed that the chairman and vice-chairman of the New England committee—John Hays Hammond and Eugene Hultman—were opposed to all-rail rates on mine-run as uneconomic, the committee's representative at the hearing favored their permanent establishment and also wanted the high-volatile fields opened up to his section of the country.

### New York Wants Same Advantages

New York's position, as outlined by the chairman of the state coal commission, was simply that the Empire State wanted to enjoy the same rate advantages that the Interstate Commerce Commission saw fit to extend to other parts of the East. Contrary to the hostility toward anthracite voiced by some of the New England witnesses, New York had no desire for a permanent divorce from hard coal. The state had launched a campaign to teach consumers how to burn soft coal solely as an emergency measure. Newark, N. J., asserted that over 1,100 families

### *Take Your Choice*

Testifying before Interstate Commerce Commissioner Campbell at New York last week, Thomas F. Farrell, vice-president of the Pocahontas Fuel Co., estimated that the anthracite strike was creating a shortage of 12,500,000 tons per month which the bituminous industry must meet in the near future. Domestic anthracite consumption during the six months of the heavy coal-burning season averages 10,000,000 tons per month, or 60,000,000 tons, against which were supplies of 30,000,000 tons. Consumption of steam sizes approximates 2,500,000 tons monthly.

By the middle of next month, therefore, the stocks of anthracite will be exhausted, forcing the consumer back upon other fuels at the rate of 10,000,000 tons of domestic coal and 2,500,000 tons of steam coal each month. To meet this situation will require the best efforts of the bituminous industry and the railroads via all routes and roads.

The bituminous industry, retorted Charles O'Neill, secretary of the Central Pennsylvania Coal Producers Association, is overmanned to the extent of 200,000 workers. Its capacity is 200,000,000 to 400,000,000 tons annually in excess of normal demands. Hundreds of mines are now idle. Central Pennsylvania alone can ship 1,250,000 tons of prepared coal monthly. How then, he asked, can it be said that the suspension of anthracite mining with an annual output of 90,000,000 tons, creates an emergency?

The only danger in the situation, as Mr. O'Neill sees it, is that the commission, by opening up all-rail routes from the more distant fields, will encourage such a wasteful use of transportation facilities in uneconomic criss-crossing and long hauls that a tremendous car shortage will develop. In other words, to establish the rates suggested in the Commission's orders will tend to create the very emergency the Commission is seeking to avoid.

## Pittsburgh Coal Co. Resumes At Mansfield Mine

The Pittsburgh Coal Co. has opened the fifth 1917 scale mine in the Pittsburgh district. Just a few days after Montour No. 10 was started, Nov. 9, at Library, Pa., the company got the Mansfield mine, in Scott Township, near Carnegie, which is only a few miles from Pittsburgh, started on the 1917 wage scale.

The Mansfield mine ships over the Pennsylvania, but the first coal from the mine will be supplied to the town of Carnegie for domestic purposes, the Mansfield grade being the best domestic coal produced in the Pittsburgh district.

It is expected to bring the total force at Mansfield mine to 350 men, and to bring the daily production up to about 1,400 tons daily.

Eight deputy sheriffs were posted at the mine, but no disorder was expected as there has been no trouble at any of the other four mines started by the company at the lower wage scale. Lance Linsley is superintendent. Harry M. White, division manager at Midland mine, is in charge also at Mansfield.

### *Report of Coal Stocks Ready by Christmas*

Plans for a survey of coal stocks by the U. S. Bureau of Mines, as announced in *Coal Age* last week, have been changed, and a survey as of Nov. 1 will be taken. The machinery is already in motion and the data will be available, according to general speculation, shortly before Christmas.

Mansfield mine was one of the last pits of the company to be closed down because of the depression resulting from inability to compete with Southern fields. It was shut down April 30, 1925.

The total number of employees in the five mines of the company in the Pittsburgh district is now 905.

---

Westbound shipments of bituminous coal through the "Soo" canals in October, 1925, totaled 1,873,482 net tons. No cargoes of hard coal passed through during the month.

---

in that city were unable to buy anthracite because supplies were exhausted and asked the co-operation of the bituminous industry in meeting the situation. The chairman of the fuel committee of the National Association of Purchasing Agents cautioned the Commission against ignoring the requirements of the rest of the country in its zeal to provide for the necessities of New England and the Middle Atlantic states.

Apparently mindful of the refusal of the Commission in its original decision to establish joint rates from the splint fields because "we have no requests by the public authorities or by the representatives of consumers in support thereof," Kanawha and related fields marshalled their battalions to meet this objection. Retail and wholesale agents told how they had demonstrated its virtues and sold splint coal in Framingham, Worcester, Holyoke, Northampton, Brockton, Providence, Fall River, Boston, Gloucester, Albany, Schenectady and Watervliet. Trial orders, they said, had led to repeat orders.

#### High-Volatile Has Innings

Exhibits were introduced to show that 73.5 per cent of the mine capacity of the Kanawha district—which has shipped approximately 400 cars to the Northeast in the past 60 days—has screening facilities and could furnish 25,000, to 50,000 tons to New England every month without robbing other sections. Logan, with the close of navigation, could offer 175,000 tons of prepared coal monthly; the Kenova-Thacker field, 60,000 to 75,000 tons. The northeastern and Big Sandy fields in Kentucky also wanted to share in the business.

Whether rates on mine-run would help to keep down prices on prepared sizes was a bone of contention, but every district pled for the same advantages that might be accorded others. As a rate basis eastbound, traffic experts suggested the differential adjustment over New River rates from the Kanawha field to Washington and tidewater, with possibly diminishing differentials as distance increased.

Operators in the Clinch Valley division of the Norfolk & Western attacked the failure of the carriers to include their mines in the rates effective Oct. 15. It was admitted that this disruption of a long established rate relationship was long contemplated by the Commission's order and it was indicated that an adjustment would be made. Similar assurances were forthcoming from the N. & W. following the recital of the complaints of Baltimore retailers on the Western Maryland that the new rates had not been published via their line, leaving their rates 75c. a ton higher than those applicable via Baltimore & Ohio and Pennsylvania R.R. deliveries. Another maladjustment of the same character, it was testified, exists at Philadelphia on Philadelphia & Reading deliveries.

Aside from the Baltimore testimony and that offered on behalf of the splint producers, the retail trade was without representation at the hearing. But the retail distributors were assailed a number of times by different witnesses. Every time complaint was made of high prices to the consumer, producers insisted that the responsibility was not theirs. The spokesman for the New England Governors' Fuel Committee declared that if proper co-operation was not forthcoming from the retailers, industries would purchase mine-run, screen out the lump and sell the large coal direct to their employees. Another witness intimated that the willingness of some retailers to handle high-volatile coal was due to their hope that the householders would be so troubled with smoke that they would flock back to anthracite when the strike was over.

---

## Engineers Hold Meeting in Anthracite Region; Inspect Modern Mining Equipment

Mining, mechanical and electrical engineers of the whole anthracite field attended the meeting of the Lehigh Valley Section of the American Institute of Electrical Engineers held at Pottsville, Pa., Nov. 13. Papers were read by men representing mining, public utility and manufacturing companies.

J. H. Pierce, assistant to the president of the Buck Run Coal Co., presented a paper dealing with the question of the use and generation of power. In his paper he stressed the business aspects of engineering work in the mining field and the necessity for lower power costs.

A thorough digest of the "giant power" report dealing with its engineering and financial phases was made by Farley Osgood, past president of the American Institute of Electrical Engineers. In comparing the estimates and plans proposed in the "giant" survey with present-day developments and practices of public utilities, Mr. Osgood showed wide differences and claimed that experiences have shown that power plant costs used in the survey were much too low.

H. D. James, who is in charge of the control department of the Westinghouse Electric & Manufacturing Co., spoke on control equipment. In his address he touched upon the details of the 1,200-hp. electro-pneumatic control equipment recently installed by the Lehigh Coal & Navigation Co. at its Lansford colliery. He also spoke about other new developments of control equipment suitable for meeting the exacting conditions necessitated by automatically operated pumps, hoists, elevators and special motor applications.

#### Inspect "Giant" Breaker

On Nov. 14, the day following the technical session, many of the engineers journeyed to Lansford, where they inspected the new breaker and equipment of the Lehigh Coal & Navigation Co. One of the first places visited by the engineers was the main hoist house where they saw a large magnetic hoist control panel and the electro-pneumatic control apparatus.

After viewing the hoisting, compressor and power distribution systems the engineers were conducted through the breaker. Here they saw the layout of a structure designed to handle 10,000 tons of product per day.

As the coal goes through the breaker it is sized, cleaned and prepared by equipment completely driven by electric motors. Many novel features in the design of the breaker to prevent rapid deterioration and degradation were thoroughly inspected. Much interest was shown in the methods by which coal is prepared because the product of the mines in this region is much different from that in the northern anthracite field. However, much valuable information was gathered by most of the engineers because the breaker structure is modern in every detail and points the way toward future progress.

## Union Gains Little Ground In Upper West Virginia; Outlaw Strike Is Stopped

Non-union coal production in the twelve and one-half counties in northern West Virginia, which are breaking from the union's control, continued heavy last week. In the first four days of the week 7,254 cars of coal was produced compared to 6,859 cars in the corresponding period of the week before. The union mines showed a slight increase. In the first four days they produced 1,064 cars compared to 1,027 cars in the first four days of the previous week. As usual, the union charged non-union operators with deliberately falsifying the record of non-union production.

Union tonnage on the Monongahela Ry. continues the heaviest in the region. The union output on Scotts Run is heavier than the open-shop tonnage, which indicates that the last stronghold of the union in northern West Virginia is there. The union tonnage reached 258 cars on Nov. 12, the heaviest daily union tonnage on the Monongahela Ry. since Oct. 29, when a similar number of cars was loaded.

On the average there were 216 non-union mines at work daily in northern West Virginia in the first four days of last week as against 14 union plants.

An illegal strike occurred at mine No. 2 of the Cleveland & Morgantown Coal Co. (the Pursglove interests, of Cleveland, Ohio), one of the largest union mines on Scotts Run Nov. 10, but the men were all back in the pits the next day. The trouble, according to statement credited to Samuel Pursglove, president of the company, was that miners wanted transportation into the plant, which he says never was provided and is contrary to the state laws. From other sources it was reported that the strike resulted from a company effort to have the men push cars uphill in the mine.

### Encourages Miners

As a means of bolstering up a lost cause, Van A. Bittner, chief international representative of the United Mine Workers in northern West Virginia, returned from a week's visit to Washington, D. C., and gave out a statement designed to hold out a ray of hope to the striking union miners.

"After conferring with our representatives in the various fields I may say that the situation in northern West Virginia is becoming more encouraging every day," said Bittner. "Approximately 500 union miners have been put to work in the Scotts Run field during the past week, and with other union operations resuming, about 250 more union miners will be employed in the next few days," he declared.

The large mine of the Consolidation Coal Co., No. 63, at Monongah, ran its first coal Nov. 10, and officials of the company say that more than 100 men are at work at the plant. This is striking into the very heart of the union's stronghold, and generally is regarded as one of the most difficult mines to work on a non-union basis in the region. It is reported that the union miners have leased a lot near the pit mouth and are picketing from there.

© Wide World Photos.

**Rev. John J. Curran**

Father Curran, who is the pastor of St. Mary's Roman Catholic Church, Wilkes-Barre, Pa., is sharing the stage with Governor Pinchot in the effort to bring the anthracite miners and operators together and settle the hard-coal strike. He has discussed the situation recently with the Governor and with President Lewis and Vice-President Murray of the miners' union and when Governor Pinchot conferred last week with Mr. Lewis and Major Inglis, Father Curran said it was "the beginning of the end." He would not explain, however, on what he based his optimistic view.

When 45 union pickets appeared before Judge Winfield Scott Meredith in Marion County Circuit Court in Fairmont Nov. 9, he did not pronounce sentence on them on charges of contempt of court growing out of picketing at the Monongah entrance to New England mine of the company at Watson but deferred action for 30 days.

Announcement has been made that the Consolidation Coal Co. has selected John S. Forinash, of Grafton, to act as its commissioner in settling disputes between the coal company and the employees now working non-union. Forinash formerly was president of Sub-district No. 3, District No. 17, United Mine Workers, but was dropped from the miners' force when the international union took over the autonomy of District No. 17.

The tipple at Whiteman mine of the Clarksburg Big Vein Coal Co., three miles west of Clarksburg, was burned down on the night of Nov. 11, causing a loss of several thousand dollars.

## Kansas Also Rock Dusts

Five mines in the Kansas field now are rock dusting, Ernest Shaw, deputy state mine inspector, announced Nov. 11. Mr. Shaw for three years has been endeavoring to persuade operators in the Kansas field to use rock dust. Those mines which now are employing it are Hamilton Coal & Mercantile Co. No. 9, Wilbert & Schreeb, Krueger Coal Co., Mackie J. and Clemens Coal Co. No. 17. Four of the five mines are dusting by hand. In the Hamilton mine, however, an electrically operated duster devised by Mr. Shaw and W. R. Hamilton and L. D. Kelley of the Hamilton company is being used with satisfactory results.

## Pittsburgh Terminal Gets Big Output at Union Wages

In October the Pittsburgh Terminal Coal Corporation had the largest output in its history for a one-month period, producing 405,273 tons from seven mines, three of which are old and full of pillar-pulling operations. The average daily output during the 26 working days (including Columbus Day) was 15,000 tons. Four of its largest mines produced 332,402 tons in the month.

The peak output for one day from the seven mines during the period was 15,800 tons, showing that the record was achieved by a consistently uniform daily output from all the mines. Although its mines are in western Pennsylvania, in the Pittsburgh seam, and are operating under the Jacksonville agreement, the company has been producing consistently for some time, chiefly by reason of the many economies it has been practicing through modernization.

## Kentucky Mine Owners Favor Rescue Autos; Rash Resigns

Members of the Kentucky Mine Owners Association, meeting in Louisville, Ky., Nov. 11, discussed movements for the establishment of mine-rescue stations in various sections of the coal fields. A number of operators think large motor trucks should be used in mine rescue work instead of railroad cars. The association believes it is doing some good with its series of advertisements to acquaint the public with the importance of the coal industry and to combat the movement for a tonnage tax. Other matters discussed were welfare work at mines, workmen's compensation laws, educational work, hospital service and matters pertaining to operation of mine camps. Action was postponed until spring on the resignation of President Frank D. Rash, who wants to quit because he is no longer an active coal man.

## West Virginia Mining Institute Announces Full Program

The program of the West Virginia Mining Institute for its semi-annual meeting, in Morgantown, W. Va., Nov. 24 and 25, follows: "Recent Developments in Shooting Coal," by J. E. Tiffany, explosives engineer, U. S. Bureau of Mines, Pittsburgh, Pa.; "Smokeless Coals of West Virginia," by David B. Reger, of the West Virginia Geological Survey; "Preparation of Commercial Coals," by Thomas Fraser, assistant professor, mining engineering department of West Virginia University; "General Use of Gunite in Coal Mining," by B. C. Collier, president, Cement Gun Co., Allentown, Pa.; "Some Observations of New Methods of Mining," by J. J. Rutledge, chief engineer, Bureau of Mines, Baltimore, Md.; "Flameproof Motor as a Safety Measure," by Frank Haas, consulting engineer, Consolidation Coal Co., Fairmont, W. Va. An inspection trip will be made to the Nemacolin mine of the Buckeye Coal Co., at Nemacolin, Pa.

# Printing of Coal Commission Report Assures Action by Congress; Coolidge To Keep Hands Off Anthracite Strike

**By Paul Wooton**
Washington Correspondent of *Coal Age*

Buried alive, like a Hindoo fakir, in a state of suspended animation, the report of the Harding Coal Commission has arisen and will walk into Congress at the very moment it is most likely to receive consideration.

The importance of the document to the industry lies almost wholly in the political situation which happens to exist as it emerges from the Government Printing Office. It seems likely that the anthracite strike will last long enough to cause widespread inconvenience. Every day that passes makes it more certain that:

(1) Coal will come in for a great deal of popular discussion this winter;

(2) The administration will not intervene in the strike;

(3) Regulatory legislation will be considered by Congress.

Had the Coal Commission's report been printed before it would have been overlooked and forgotten. Those volumes that had escaped the waste basket would have been festooned with cobwebs alongside that imposing array of major prophets "First Frelinghuysen," "Second Frelinghuysen," "Third Frelinghuysen," "First Calder," "Second Calder," "First LaFollette," "Second LaFollette" and "Third LaFollette," to say nothing of works of the minor prophets and epistle writers in the House of Representatives.

As authors, Mr. Hammond and the other members of his commission are in luck. The delay in its printing has insured it an amount of attention infinitely greater than would have been the case had it been issued in final form at the time it was completed.

### Can Sidestep Blame

The issuance of the report at this time also is fortunate for the administration as it furnishes an additional reason for referring to Congress those who are clamoring for relief. The administration is in an enviable position in that it can point to the Commission's recommendations without coming in for blame for those that are distasteful. Mr. Coolidge is not the father of the Commission. He acts more like its bachelor uncle. He is holding the baby gingerly and uncomfortably on his knee. He will be more than glad to hand it over to Congress without venturing an opinion as to whether it is a girl or a boy and certainly without offering to adopt it.

Then, too, it must be admitted that the report clothed in the decency of print will command more respect than it did when it appeared in the shoddy of mimeograph. As it emerges from the federal print shop it is composed of four volumes of text and an appendix of statistical tables and charts. It is annotated and thoroughly indexed.

The report presents a finished appearance and is certain to create the impression in Congress that the Commission took its task very seriously and sought the facts patiently, accurately and exhaustively. The very ponderousness of the volumes is an argument against any further investigation before action by Congress. When coal comes before Congress for discussion those who seek to avert legislation will employ the usual tactics and demand that the question be given more study. Those who favor legislation now will be in a position to say: "If this Commission, composed of distinguished men, backed by a great array of expert talent, with ample funds and a year's time could not get the facts, who could get them?"

The Commission's recommendations for legislation also are being printed separately and will be available for much wider distribution than the report itself. These recommendations form a separate pamphlet of twenty-three pages.

### Would Counteract Sentiment

Since many thousands of that pamphlet will be circulated there is a feeling among those who oppose any legislation that something definite and positive should done to counteract the sentiment which the document is likely to arouse. They admit that the recommendations for legislation possess a certain simplicity and plausibility and outline a public policy that is certain to appeal to the public. They feel that it is not enough for the industry just to wave aside the whole Commission program as dangerous doctrine. The feeling is that the industry must throw off its purely negative attitude and must be specific as to the errors it finds in the report and to what it objects. There is a decided conviction on the part of some within the industry that those in the business should work out a program of their own to meet definitely the criticism of the Commission and the demand of the public for the facts.

The recommendation of the Commission for fact finding and a uniform system of accounting already has many supporters. Outside the coal trade itself the recommendation that the reports be compulsory, as are those of the railroads, will not frighten. The Commission recommends that the Interstate Commerce Commission act as federal fuel distributor in periods of shortage, with such powers, in addition to those of the Transportation Act, as may be necessary. This will appeal to a considerable portion of the public as the least that should be done in emergencies. There will be some public support even for the proposal to license companies engaged in interstate commerce.

In one respect at least there is no reason to believe that Congress is ready to go further than the Commission. The Commission did not recommend compulsory arbitration of trade disputes. Instead it would authorize the President to make a compulsory investigation when the two parties are unable to agree on the renewal of a wage agreement. There can be no doubting that there is a group in Congress ready to advocate a compulsory tribunal on the ground that coal is affected with public interest.

## *Coal Mines Pay Heavily to Compensation Fund*

An actuarial survey of the present reserve of the workmen's compensation fund of West Virginia having been authorized by the Legislature, Governor Gore has appointed Emil E. Watson, of Columbus, Ohio, to perform the work. Ten thousand dollars was appropriated for the survey, but Mr. Watson has contracted to do the work for $3,500. According to Walter H. Cunningham, secretary of the West Virginia Coal Association, total premium receipts of the commission for the fiscal year ending June 30, 1924, were $3,469,000, of which the coal industry paid $2,386,000. Premiums were paid into the fund on a total payroll of $305,000,000, of which $162,000,000 represented coal companies.

"While the number of fatal accidents is larger in the coal industry than in any other in the state, due largely to the magnitude of coal operations," says Mr. Cunningham, "the 1924 report shows that of 29,000 non-fatal accidents, only 12,000 occurred in the coal industry, against 17,000 in other industries."

---

## Americans Acquire Control Of German Mines

W. A. Harriman & Co., of New York City, and the Anaconda Copper Mining Co., of Montana, have jointly taken over the German-Polish holdings of the Georg von Giesche Heirs, Inc., a firm that is said to have been in financial straits. The holdings include zinc mines, smelters and coal mines. The importance of the coal mines to this industry was such that in 1815, owing to the low price of zinc and the high price of coal, the zinc works were moved from Scharley to Georgschütte so as to be near the coal mines at Michalkowitz. These latter mines the new interests will direct though not own.

Soon after the passing of control to the Harriman company took place it was announced that steps were being taken to test the legality of the contract. The Prussian State Attorney General has dug up for this purpose an old law whereby an attempt will be made to show that the arrangement with the Americans is detrimental to the welfare of the people and the nation and therefore illegal. At the same time the Prussian State Mining Corporation has taken measures to enforce its contract, which it asserts was concluded with the Giesche firm before negotiations with the Americans were concluded.

## Moshannon Mine Men Devote Sessions to Troublous Questions

A broad field of interest was covered by the questions and discussions at the Moshannon Coal Mining Institute's fifth annual meeting, Nov. 14, at Philipsburg, Pa., eighty-five persons being present. At the afternoon session Thomas Mather presided.

The advantages and hazards of mechanical loaders and conveyors were discussed. Joseph Knapper recalled that when mechanical undercutters were introduced the same fears were entertained as are expressed today with regard to machinery for loading. He thought and trusted that the present apprehensions, where entertained, would prove unjustified. It was suggested that the loading of coal into unbroken trips instead of into separate cars would do much to prevent accidents both from coupling and from runaways. Locomotives also would not be running all over the mine. Another speaker showed that where machine loading had been introduced the accident rate had been lowered, but questioned what could be judged from that fact as in every case cited the roof conditions were favorable.

Discussing whether it is "advisable to conduct the intake air the full length of the split or to have it enter the split at several different points" it was said that, suppose sixty men were working in a split consisting of three gassy entries, the air supply would have to be 12,000 cu.ft. per min. Would it be better to put 4,000 cu.ft. into the first entry, containing only twenty men; 8,000 in the second, containing another twenty, and 12,000 in the third, in which twenty others worked?

### Regulators Prevent Power Saving

Mr. Knapper said it would be necessary to use regulators in the first and second entries to get this distribution, and consequently there would be no power saving and at the same time the current of air in the first entry would be insufficient probably to sweep out the noxious gases.

Someone wanted to know why if enough air was available for three splits and the air thus split would sweep out the noxious gases, three wholly separate splits were not used and power saved, but apparently the idea was to keep the overcosts down to the lowest possible number. It was pointed out that if the first entry gave out too much gas for 4,000 cu.ft. of air to dilute, it might be possible to go on working if 12,000 cu.ft. were carried through all three entries, provided the other two entries gave little gas. The chances were that by passing the 12,000 cu.ft. through all three entries the air would be less likely at any time to be overcharged with gas than it would be if lesser quantities of air were taken through two out of three entries.

Another question was, "What effect does a heavy short-circuit on a direct-current line have on the alternating-current demand meter? None at all, said the electrical engineer of Hale Coal Co., provided a circuit breaker operates to close the circuit. He admitted that a heavy ground—that is, a short that would not throw out the circuit breaker—might have a marked effect on the demand meter, provided it continued for sufficient time—say 15 minutes—which is apparently the time on which the demand rate is fixed in the Moshannon region.

Discussing the effect of different kinds of explosives on the quality of coal, a powder manufacturer's representative declared that the time was past when the powder salesmen would contend that as much large coal could be obtained by the use of permissibles as by the use of black blasting powder. However, the size could be improved in the use of both if care were taken. It was suggested that men leaving mines where black blasting powder was in use should be carefully instructed when entering mines where permissibles were used. In this way this work might be made more effective. F. T. Powers, state inspector at Frostburg, Md., said that experiments made by himself and Dr. J. J. Rutledge, the chief engineer of the State of Maryland, with pasteboard tubes as a means of air spacing between the permissible and the tamping had proved quite successful, increasing the percentage of lump and decreasing the need for using as much explosive. Fortunately the Maryland laws did not require tamping clear from the explosive to the mouth of the hole, and air spacing was being used of length graduated to the length of the drilling. No shots thus tamped had blown out. Several companies were using air spacing and getting larger coal as a result.

At the dinner the speakers were Dean E. A. Holbrook and Wm. R. Chedsey, both of State College; F. T. Powers, C. B. Maxwell and R. D. Hall. C. B. Maxwell presented a watch to Joseph Knapper on behalf of the mining men of the Eighth Bituminous District of Pennsylvania. Mr. Knapper recently resigned as inspector, a position he had held for thirty years. Mr. Hall's address, which was the scheduled talk of the evening, was on mining conditions in Wyoming and Utah.

At an election of officers, Joseph Knapper was elected president and T. B. Gallegher, S. H. Eastman, G. H. Brightman and Andrew Fremburg vice-presidents; Thomas Morgan and William George were re-elected as secretaries.

## *Arkansas Supreme Court Lifts Receivership Against District 21, United Mine Workers*

Chancellor J. V. Bourland, of Fort Smith, Ark., had no right under the laws of Arkansas to appoint a receiver for District No. 21, United Mine Workers, the Arkansas Supreme Court ruled last week in granting a writ of prohibition restraining proceedings under the receivership.

The Supreme Court said that the union organization, being a voluntary unincorporated association, cannot be sued in its society name and that for that reason no proper service was had upon it in the receivership action.

The receivership was granted by Chancellor Bourland on application of the Greenwood Coal Co., the Mammoth Vein Colliery Co., and the Backbone Coal Co. These companies alleged that their properties had been damaged to the extent of $90,000 and that their workmen had been injured by members of the miners' union as a result of the strike. The receivership order named Senator J. F. Brewer, of Fort Smith, as receiver and authorized him to seize funds of the union in various banks, pending decision of the case.

After a motion to set aside the receivership had been overruled by Chancellor Bourland, the union and certain individual members applied to the Supreme Court for a writ of prohibition to restrain proceedings under the receivership.

## *Scranton Uses Soft Coal*

A striking demonstration of the horrors of war was seen in the anthracite region last week when forty-two gondolas of West Virginia bituminous coal were being sold and distributed among the householders of Scranton, Pa., in the heart of the hard-coal region. The spectacle of five retail coal yards in Scranton distributing soft coal brought home to both sides the fact that if they can not hold their local markets they have a slim chance of inducing anthracite users in New York, New Jersey, New England and the Northwest to refrain from the use of substitute fuels.

The dealers who received the soft coal are conducting a vigorous campaign of instruction to housekeepers in its use as an anthracite substitute.

## Delayed Blast Entombs Three Alberta Miners

Three miners were entombed by an explosion which wrecked a new prospect coal shaft at Kirkpatrick, six miles west of Drumheller, Alta., Nov. 13. Rescue crews worked throughout the next day without being able to push through the débris that covered the victims, and hope of rescuing them was abandoned. The three men entombed are Mike Gilday, J. McLane and L. Burke. A delayed powder blast is believed to have caused the explosion.

# Problems In Underground Management

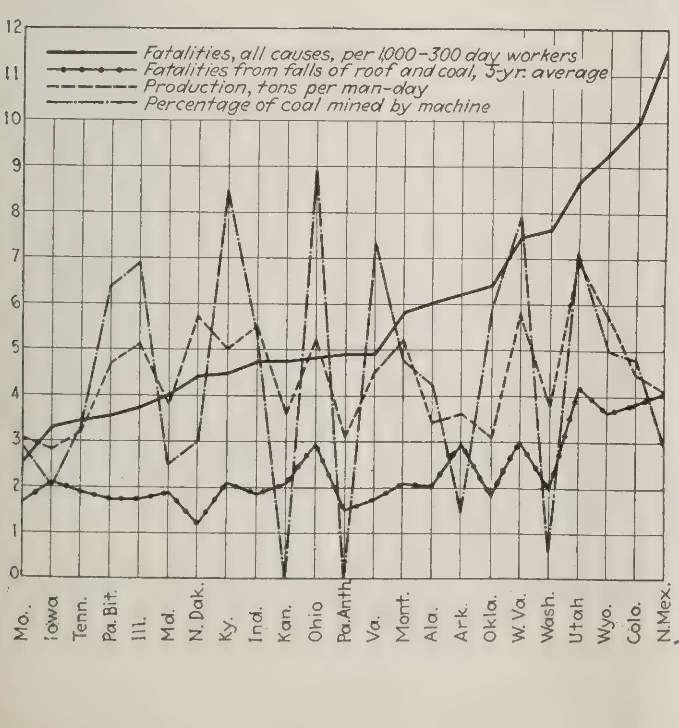
## Large Output per Man Not Accompanied By Fatalities from Falls of Roof

T. T. Read of the United States Bureau of Mines at the meeting of the National Safety Council, Sept. 29, presented a chart indicating that fatalities from falls of roof had no direct relation to high output per man per day, nor to the percentage of coal mined by machine. On the chart was plotted, against the various coal-producing states, the fatalities from falls of roof and coal for a 5-yr. average, the production in tons per man-day, the percentage of coal produced by machine and the fatalities from all causes, the fatalities being based on 1,000 three-hundred-day underground workers, using the figures presented in Bulletin No. 251 of the U. S. Bureau of Mines.

The curves thus obtained seem to bear no relation to each other and indicate that machine mining does not increase fatalities nor does large production. Utah, for instance has a large output per man and a high accident rate from falls of roof, but North Dakota, which has a high output per man, has the lowest accident rate from falls of roof of any of the states.

Mr. Read stated that a study of the chart would convince any one that our high fatality rate in America has no direct relation to the demand for speed in production, and suggested that our high rate per man employed perhaps results from the smaller number of men required to do a job of work in the United States.

Mr. Read declared that even a perfect system of timbering would not entirely remove the danger of accidents from falls of roof and coal for both in England and the United States, when the roof is naturally good the fatalities usually run higher than where the roof is naturally bad, indicating that the confidence arising from a belief that falls would not take place leads to a lack of watchfulness against the possibility of accident.

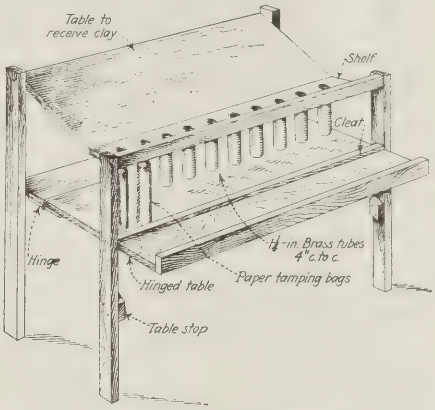


**Big Output Is Not to Blame**

Our large production per man is not the cause of our fatalities as the chart shows, nor is the use of machines. So, apparently, slowing down would not help us. The figures for mining machines should be taken in tens and not in units. Thus Ohio mines about 90 per cent of its coal by machines and Arkansas somewhat less than 10 per cent. Both have high fatality rates from falls.

## Dummies Made Above Ground Provide Clay for Tamping

Complete detonation of an explosive which obtains the best results with a minimum quantity of noxious fumes, it is well known, is facilitated by proper tamping. It is no easy matter, however, to see to it that clay sent under ground for this purpose is properly and habitually used. Many miners are averse to filling tamping bags and charge them with bugdust if this material happens to be handier than the clay provided by the management.



**Dummy-Filling Table**

By aid of this simple home-made device one man is enabled to fill and prepare as many as 4,000 dummies in one shift. The work is neither arduous nor difficult and good tamping material comes to the miner in such handy shape that he gladly uses it in preference to any other material.

A number of mines, accordingly, have adopted the practice of filling tamping bags on the surface and sending them into the mine ready for use in shot holes. Frank R. Wicks, general manager of the Empire Anthracite Coal Co., of Pulaski, Va., has devised a filling apparatus by aid of which as many as 4,000 such bags may be charged and made ready for use in eight hours.

This equipment is simple. It consists of a table inclined at 35 deg. with a horizontal shelf at its lower edge. The table is intended to receive the clay and the shelf is provided with a row of holes 4 in. apart, each fitted with a brass tube 1¼ in. in diameter and 10 in. long, extending well beneath the shelf. Underneath the lower end of the tubes is a hinged drop table.

With the drop table lowered a 1½-in. tamping bag is slipped over the bottom end of each tube. This table is then raised affording support to the bags which slip upward on the tubes. Screened clay is then placed on the inclined table and quickly runs down onto the shelf and into the tubes, the operator meanwhile aiding this process by spreading the clay with a trowel. When all the tubes are full the drop table is again lowered, the bags following it, their ends resting eventually against a cleat on the table. Clay from the tubes of course flows into the bags as they descend. The operator now removes the bags from the tubes, folds over their ends, and packs the dummies, now ready for use, into boxes preparatory to sending them into the mine.—Abstracted from *Explosives Service Bulletin*, October, 1925.

## Salt Allays Coal Dust

By W. H. Hunt
Central City, Ky.

Much has been written recently concerning the use of stone dust as an explosion preventive in mines. The practice of stone dusting is extremely interesting, appears to be efficient and bids fair to be almost universally adopted. While state mine inspector for the second district of Kentucky, however, I experimented with the use of common salt as a means of allaying the combustible dust of a mine, with some decidedly interesting results.

On one of my trips of inspection to a certain big mine I noticed one entry, known as the Tenth North, that was heavier with dust than the remainder of the underground workings. Not only was the dust deep but it was particularly dry, so I believed that this entry would be an excellent place for a trial of salt. Accordingly I ordered the dust removed from all surfaces along this passage. Some 40 carloads of it were loaded out the next day. Examination of room ribs showed that they were covered with coal dust as fine as flour, every crevice being filled with it.

A barrel of salt was brought in and scattered broadcast along the roadways, ribs and all slate and refuse heaps along this entry.

Two days later I inspected the results of this test. At that time the road had the appearance of being greasy from one end to the other. I then selected four of the worst rooms I could find and when the miner loaded his shots the next day I had him tamp into each hole a 6-in. dummy containing salt. When the shots were fired this was projected into the air as a fine powder, and thus mixed intimately with the dust of floor and ribs where with it it soon formed a pasty, greasy-looking mass. This absorbed and did away with the coal dust as such. It simply made a mud of what a few days before had been a highly explosive powder.

Later salt was used throughout the entire mine and proved highly satisfactory. It constitutes a decidedly economical dust remover. A barrel of it, if properly scattered, is sufficient to treat an average mine and will last indefinitely. It will be found also that it not only does away with dust but acts as a humidifier as well.

## This Stop Effectually Holds Cars on Mine Slope

Where the grade of a mine track is steep and single rope haulage is employed, it is frequently advantageous to provide a dependable stop that can be set to prevent cars from passing but which can be lowered so as to allow cars and trips to pass over it freely when necessary. It is desirable also to locate the device controlling such a stop at some distance from it so that the person operating the lever may be entirely in the clear.

The accompanying illustration shows a stop of this kind installed on the main slope of Mine No. 7, of the Union Pacific Coal Co., at Winton, Wyo. In this mine the main track is on a slope of 13 deg. The stop consists of a pair of heavy rails carried on a shaft that turns in boxings securely welded to the flanges of the track rails. This shaft is provided with a crank at its end so that the rails may be brought into proper position for stopping the downward movement of cars or lowered into the clear as expediency may require. The stop is actuated by a rope or cable that passes up the slope to a lever working in a quadrant. The arrangement is such that the stop rails when in the operative position are backed by a heavy block of concrete, 4 ft. high and 4 ft. wide at the bottom. This device is sufficiently heavy and strong to effectively prevent the cars from passing down the slope yet can be readily brought to the off position if desired.

In this drawing also may be seen at the left a device intended for a somewhat similar purpose, yet built on an entirely different principle. This is the stop for empty cars. It is a kind of a trigger or hook, operated or raised by a lever at the side of the track. This carries a lip or hook at its forward end that may be raised to engage the axles of the empty cars. In this position it effectively prevents them from passing down the slope to either the main or material track. A slight movement of the lever, however, by means of the toggle joint links connecting it with the stop, is sufficient to lower the trigger and release the cars. The trigger is securely pinned at its forward end to the rails of the empty track, affording a grip that cannot readily be broken.

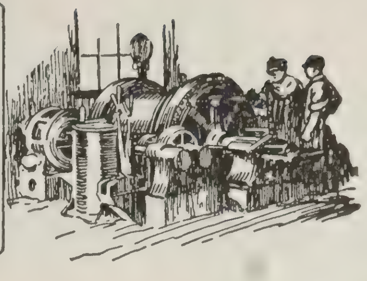
**Details of Stops for Loaded and Empty Cars**

This arrangement, operated by a lever from a distance, is heavy and strong enough to resist the movement of cars or trips yet readily may be brought to the off position allowing trips to pass freely. The empty stop on the left prevents downward movement of the empties, but can be set or released by a movement of its operating lever.

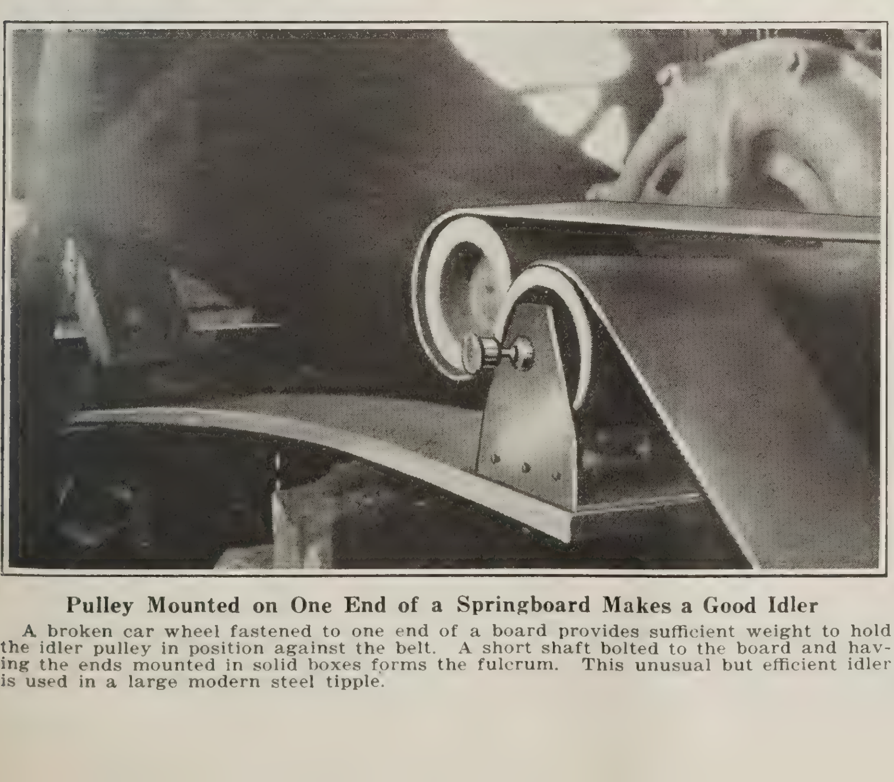
# Practical Pointers For Electrical And Mechanical Men



## Idler for Belt Drive in Indiana Mine Mounted on Springboard

As there are more ways than one to "hang a dog," there are likewise several ways to make an idler. An unusual but satisfactory form of idler is used on a belt drive in the modern steel tipple of the Pike County Coal Corporation, at Petersburg, Ind. This idler consists of an 8-in. pulley mounted on one end of a 1½x12-in. oak board, 8 ft. in length. The board is balanced on a fulcrum about 18 in. from the center of the idler. On the outer end of the board a weight consisting of a broken car wheel holds the pulley against the belt.

This idler is used in connection with a 40-hp., 700-r.p.m. motor which drives the shaker screens. The motor pulley is 9 in. in diameter, the shaker pulley 60 in. in diameter and the belt center distance is only 8 ft. The idler pulley is lubricated by a compression grease cup mounted on the end of the hollow shaft. The fulcrum under the board is arranged so there is no possibility of slippage. A short piece of round shafting bolted to the board forms the fulcrum and the ends of the shaft are mounted in plain solid boxes. The self-adjusting feature of the idler automatically takes care of ordinary belt stretch, and the method of lubrication is such that little attention is required.



**Pulley Mounted on One End of a Springboard Makes a Good Idler**

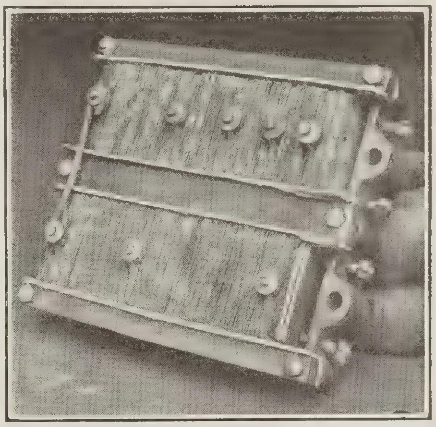
A broken car wheel fastened to one end of a board provides sufficient weight to hold the idler pulley in position against the belt. A short shaft bolted to the board and having the ends mounted in solid boxes forms the fulcrum. This unusual but efficient idler is used in a large modern steel tipple.

---

## Cap Screws Hold Resistor Plates Tightly

There are in use a great many mining machines which use a rheostat of the type shown in the illustration. This type is made up of a number of resistance plates separated by mica insulation and mounted in a cast-iron box having one open side. When repairing these rheostats it is not an easy matter, without special tools, to pack the plates tightly. This difficulty is overcome at the Fordson mines at Stone, Ky., by adding the four cap screws which can be seen at the right on the rheostat frame.

Hexagonal-head, ⅜-in. x 1½-in. cap screws are used. These act against heavy plates inserted at the ends of the stacks. By this method there is no difficulty in getting the required number of plates in the box, and the assembly is held snugly in position.



**No Trouble to Get All of Them In**

This photograph shows how compression screws are added to mining machine rheostats repaired in the shop of the Fordson Coal Co., at Stone, Ky. Holding the resistance plates snugly prevents trouble.

---

## Repair Made to Breaker Carrying Current

It is not the usual practice to work on oil circuit breakers when the power is on them but occasionally some repairs not affecting the current-carrying parts can be thus made.

Recently I had a job which necessitated such a repair and hit upon a scheme which worked out quite successfully. The breaker in question had a burned-out overload relay coil and in order to remove it the back of the operating lever had to be dismantled.

To disconnect this lever and at the same time hold the contacts of the switch together, a block of wood in the shape of a wedge was placed under the crossbar upon which the contacts are mounted. When this was done, the switch was locked in the closed position and the operating handle was dismounted. In this manner the relay coil was replaced with a new one and the operating handle again put in position.

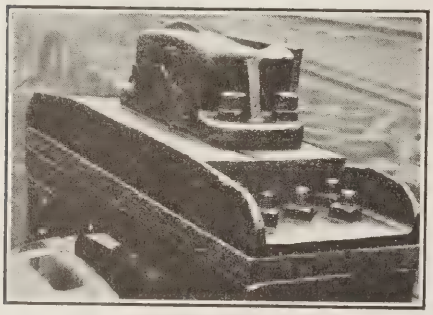
Grady Emerson.

## Draw Pockets Saved by Wood Fillers

An item which caused the mechanics of the Island Creek Coal Co., of Holden, W. Va., considerable trouble was the breakage of draw pockets of mine locomotives. It seemed almost impossible to keep the bolts tight. If those on one side loosened slightly while those on the other remained tight, any stress imposed would break off the corners on the tight side of the draw pocket.

This breakage was overcome by mounting the draw pocket on a 3x12x23-in. oak filler block. The wood is sufficiently soft that it crushes if the bolts get loose on one side and the draw pocket is tilted from its normal position. This cushion effect under the tight side saves the lugs from breaking.

No draw pockets are changed at the mines. Instead, a complete bumper is sent out from the shop to replace an old one. The fastenings are made by means of twelve rivets. It has been found that the mine electricians can be relied upon with more certainty to do a good job of riveting, than of assembling the bolted parts of a bumper.



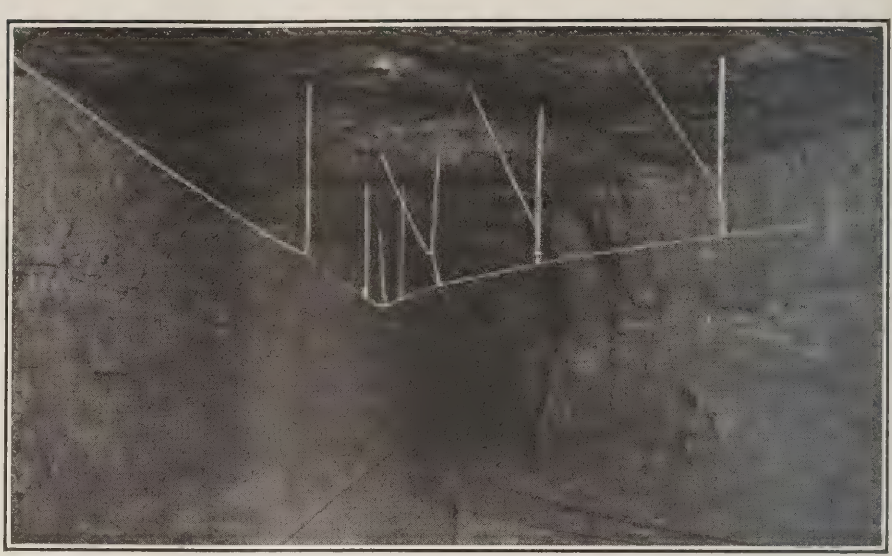
**Draw Pocket With Cushion Block Does Not Break**

By using a wood filler under the draw pocket the corners are saved from breaking if the bolts work loose. No draw pockets are changed at the mines, instead, complete bumpers are applied.

## Braces Hold Hangers in Position on Curves

An example of good trolley construction on a high roof in a wide place is shown in the accompanying photograph of a junction point of the main haulways in the Balkan mine of the Southern Mining Co. This mine, located at Balkan, Ky., is in the TeJay seam and the average thickness of the coal is about 53 in. At the point shown, which is not far from the drift mouth, about 6 ft. of bottom has been taken up to reduce the grade.

In the narrow places the trolley is supported from brackets set in the rib but in wide places, such as shown in the illustration, roof supports are used. The extension rods in the Balkan mine are made of $\frac{3}{4}$-in. galvanized pipe. Those above the straight track are not braced but those on the curves are braced on the tension side by straps $\frac{1}{8}$ in. thick and $\frac{1}{4}$ in. wide. This construction has been in use for several years. It has proven satisfactory and presents a neat appearance.



**Side Braces Hold the Wire Where It Belongs**

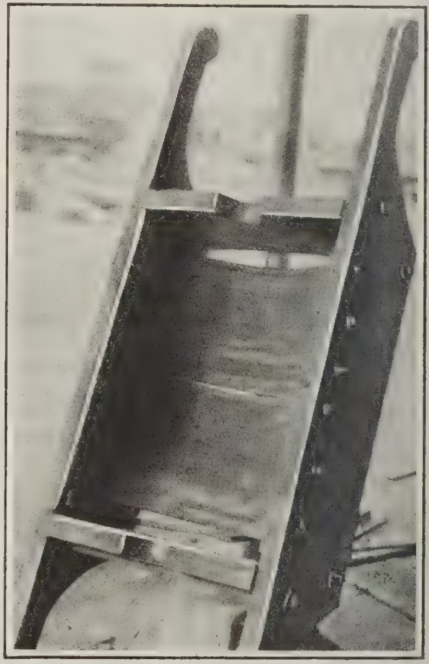
About 6 ft. of bottom has been taken up at this point to reduce the grade. The mine is in the TeJay seam and the coal averages 53 in. in thickness. Long cross supports could not be used but the extensions and braces make it possible to hold the wire in place. The side braces are used only on the line above the curved track.

## "Stretcher" Insures Safe Handling of Armatures

Armatures, despite their electrical strength and reliability, are somewhat complicated and delicate from the mechanical standpoint. Accordingly, these machine parts require careful handling when they are removed from their bearings. The accompanying illustration shows an armature "stretcher" or sling used at the mine shops at Valier, Ill., and designed to facilitate the transportation of armatures without injury to such parts as windings, commutator or bearing surfaces.

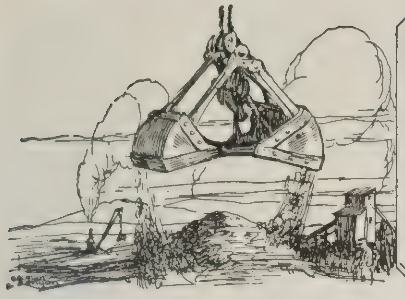
This device is extremely simple in its construction. It consists of two side pieces of light plank so cut as to form end grips to facilitate carrying. Between the side pieces are two end blocks, each provided with a notch to receive the armature shaft. These are bolted securely in place and serve as spacers; also attached securely to the sides by means of a strap and bolts are two pieces of old rubber belting.

Into the cradle thus formed an armature may be laid without fear of injury. The width of the frame and the belly of the belting is such that the "stretcher" with an armature in it may be set down upon the floor or other level support without danger of the belting touching. The armature is thus well protected and there is small chance of its receiving mechanical injury while being transported either to or from the shop.

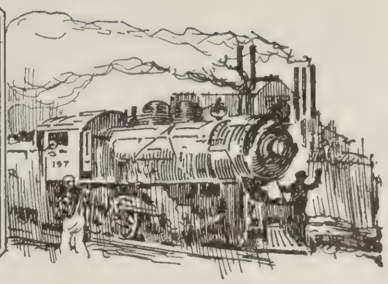


**Armatures Are Carried Safely in This "Stretcher"**

Even though this carrier, which will accommodate armatures of various sizes, is set down on slightly uneven ground or upon floor strewn with such objects as bolts, nuts, rivets or tools there is small likelihood of the armature being injured. The belly of the bed is less than a semicircle and even if some object, such as a nut, should come in contact with the belting this material would amply protect the armature resting upon it.



# Production And the Market



## Bituminous Coal Market Follows Even Pace; Undertone Is Firm

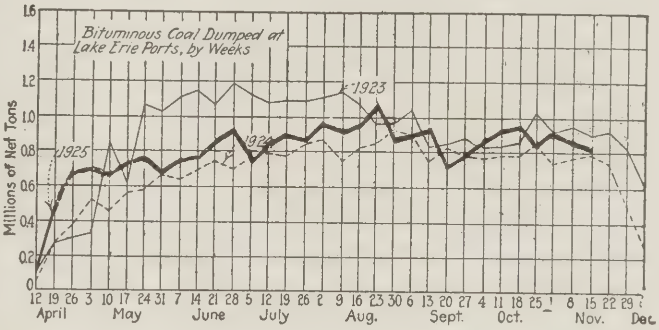
Despite the fact that production of bituminous coal continues above the twelve million-ton level the market retains much strength—a surprising amount in view of the comparatively mild weather thus far and the tendency to slump that usually appears in the wake of a sudden spurt such as that of a few weeks ago. The reaction seems to have been confined almost entirely to the market for anthracite substitutes, principally coke, which a few weeks ago was hitting only the high spots, but which took such a sudden flop that some of the top quotations have fallen $2@$2.50. Screened and prepared coals, which were next to coke in public preference as hard-coal substitutes, also have been gradually easing off as the demand for mine-run has been gaining headway. A sudden fall in temperature, which would quickly stimulate domestic demand, might, of course, cause another upturn, though it is not likely that recent high levels will again be attained.

Business in steam grades is fairly good, most holders of contracts taking full quotas, but with output at a high level and the sharp edge missing from domestic call, due to mild weather, there is no difficulty in taking care of requirements. Four mines in eastern Ohio reopened last week and several others are said to be ready to resume as soon as a favorable opportunity presents itself—when that will be, however, is somewhat doubtful in view of the closing of the lake season.

Movement of coal through the Cincinnati gateway fell off somewhat last week, 13,011 cars having passed through, which, however, was an increase of 302 cars over the corresponding week a year ago. The lake season closed with a record-breaking run of 2,103 cars.

Anthracite is virtually out of the wholesale market and retailers having hard coal are apportioning it among regular customers in small lots. After holding separate conferences with President Lewis of the miners' union and Major Inglis, of the operators' scale committee, Governor Pinchot is working on a plan to get the miners and producers together and bring about a settlement of the strike.

Production of bituminous coal during the week ended Nov. 7 is estimated by the Bureau of Mines at 12,189,000 net tons, compared with 12,480,000 tons in the preceding week. The decline is attributed partly to the election holiday and partly to the observance of All Souls Day. Anthracite output in the week ended Nov. 7 totaled 28,000 net tons, an increase of 10,000 tons over the previous week.



*Coal Age* Index of spot prices of bituminous coal on Nov. 16 stood at 190, the corresponding price being $2.30, compared with 185 and $2.24 on Nov. 9.

Dumpings of coal at Lake Erie ports during the week ended Nov. 15, according to the Ore & Coal Exchange, were as follows: Cargo, 759,058 net tons; steamship fuel, 44,738 tons—a total of 803,796 net tons, compared with 842,813 tons in the preceding week. Hampton Roads dumpings during the week ended Nov. 12 totaled 402,152 net tons, against 398,123 tons in the previous week.

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Midwest Market Keeps Even Pace

The Midwest coal market maintains a fairly even pace without much excitement either in the domestic or the steam end of the business. Franklin and Saline County producers, and some in Williamson County, raised their prices on 6-in. lump a few days ago from $3.25 to $3.50. Most of the operators, finding that they were far behind on lump commitments, wished to draw some attention of the buying public to 6x3-in. furnace and 3x2-in. egg. High-grade Indiana Fourth Vein 6-in. lump has not as yet gone up to $3.50, although this is expected as soon as another cold snap appears. Central Illinois lump is reasonably firm for high-grade coal at $3@$3.25. The smaller domestic sizes are at lower levels, the price being set principally by the demand.

Steam coals are offered at all sorts of prices, ranging from 85c. on west Kentucky strip screenings up to $1.75 for good southern Illinois 2-in. screenings. Buyers are in the market, but, realizing the increase in production of steam coals, are driving as close bargains as they can for current needs. It is interesting to note that some of the largest industries are buying coal on the open market rather than on contract, as in years past.

The situation on Eastern coals is a little more complicated. There is a wide range in price on fancy grades of eastern Kentucky and West Virginia block—from $3.25 to $4. Those who appear to be getting a premium are the sales agents or operators who produce high-grade coal and have car numbers available to give to their trade. Smokeless lump, egg and nut have weakened perceptibly in Chicago; in fact, some operators have had to shade prices from 50c. to 75c. a ton in order to dispose of coal in transit. Good prepared coal has a range of $5.50@$6, egg bringing anywhere from 25c. to 50c. a ton over the price of lump. The best smokeless mine-run can be purchased at $2.50@$2.75, with plenty of coal offered at $2.25. Anthracite has practically disappeared from the market.

Seasonable weather is creating an unusually good market in southern Illinois for domestic lump, but egg and nut are slow and the other sizes are heavy. This is especially so in the Williamson-Franklin County field, where on Nov. 10 the price was raised 25c. a ton on lump, and in order to move other sizes there is a threat that lump and egg will advance another 25c. on the 18th. The shaft mines are getting pretty good working time although all of them have "no bills" on hand every night. Strip mines are doing well with a ready market. It is understood, however, that there are many idle mines in all of these fields. A car shortage is slowly developing. In the Duquoin field conditions are somewhat similar to those in Williamson and Franklin counties. Working time is about five days a week and prices range from 25c. to 50c. under the Franklin County circular.

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Nov. 16 | Nov. 9 | Nov. 2 | Nov. 17 |
| Index | 190 | 185 | 181 | 170 |
| Weighted average price.. | $2.30 | $2.24 | $2.19 | $2.06 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and, second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

The Mt. Olive field shows considerable activity. Railroad tonnage is good and domestic shows an increase, with a little steam moving slowly. Prices in this field advanced recently to $2.75 for St. Louis shipments and $3 for country shipments on domestic lump. Business in the Standard field is hand to mouth. Prices are just about the cost of production. The demand is good for lump but there is no call for anything else. Working time is anywhere from three to five days a week. Railroad tonnage is fair. The latest reports indicate that there is a possibility that the consolidation of mines in the Fifth and Ninth districts has a chance now of going through, as some of the large operators who held out in the beginning have recently indicated a willingness to come in.

Fairly seasonable weather at St. Louis means fairly good movement of domestic coal—not alone of high grade, but middle grade as well. Anthracite and smokeless show poorly, but coke continues to improve. Local wagonload steam is good and carload is fair. There is a fairly good movement of domestic to the country, preferably middle grade. Country steam is quiet. St. Louis retail coal prices are expected to advance between Nov. 15 and 20.

### Heavy Tonnage Moves from Kentucky

Movement from Kentucky continues very heavy, it being reported that some coal is moving to Canada and east as far as Buffalo, and a lot is going into markets that formerly handled a good deal of smokeless coal, which has been passed up on account of the present prices. Relatively warm weather in Louisville has caused a slump in local demand for both steam and domestic sizes. River movement south from western Kentucky is getting under way again after a long shutdown due to low water.

In western Kentucky fine screenings (pea and slack) is being sold at 65@85c., with nut and slack at 90c.@$1. Not much nut and slack is offered, however, as most operators screen for nut, and buyers prefer fine screenings for use in automatic stokers.

Quotations as high as $4.50 a ton are heard on best grades of specialty eastern Kentucky 4-in. block coals, but $3.25@$3.75 catches most of the movement.

Rural movement over Kentucky and nearby states has been picking up somewhat, but the larger city retailers are not taking to higher prices very well.

Car shortage is more pronounced and distribution worse, a great deal of the trouble in eastern Kentucky being due to cars being held under load at lake ports.

### All Lines Firm in Northwest

Dock operators at Duluth-Superior have been putting through substantial sales of both anthracite and bituminous coal, but warmer weather has caused a slackening as compared with the latter half of October. Markets are firm in all lines of anthracite and bituminous coal and dealers show no disposition to take advantage of any shortages of supplies. Anthracite dock prices are: Egg, $13.20; nut and stove, $13.60; pea, $11.05; buckwheat, $6.50.

Demand for Pocahontas (as a substitute for anthracite) is the heaviest in the experience of the trade here, but prepared sizes are still $8.50@$9 and other lines of bituminous coals are unchanged.

Industrial buying is steadily gaining over Minnesota and northern Wisconsin, iron-mining companies on the Minnesota ranges having increased orders for mine-run and screenings.

Domestic orders for anthracite have been on such a heavy scale that it is now figured that the exhaustion stage in all sizes will be reached by about Feb. 1.

Last month's shipments from the docks were the highest in several years—31,685 cars—as compared with 24,032 cars during the preceding month and 26,418 cars during October last year. The docks received from Lake Erie ports 1,242,816 tons of bituminous but no anthracite during October. Total receipts of soft coal to Nov. 1 were 7,688,638 tons, an increase of 1,425,975 tons over the same period last year. Anthracite receipts were 786,848 tons, a decrease of 390,423 tons from last year. Bituminous stocks on the docks are now placed at 5,450,000 tons, of which approximately 2,000,000 belongs to the railroads.

Twenty-nine cargoes of coal were unloaded at the docks last week and thirteen, including one of anthracite screenings to be used by a Superior company in making briquets, were reported en route.

Coal demand in Milwaukee has slackened due to milder weather. Anthracite virtually is out of the market, and in consequence consumers who can burn bituminous coal are turning to the better grades, which are firm in price and looking upward. There is a strong demand for coke, and prices are advancing. Local dealers now get $15 for range coke, $14 for the nut size, and $12 for pea. No anthracite has been received since Sept. 15, but cargoes of bituminous coal are coming in as usual. Receipts for the season of 1925 to Nov. 13 total 3,305,001 tons—488,234 tons of anthracite and 2,816,767 tons of bituminous coal.

A touch of Indian summer has slowed down the demand for coal in various directions in the Twin Cities, but a fair tonnage is moving, both at retail and in the steam trade. It is not at all certain that there will be any great shortage of hard coal, for the trend to other fuels has been pronounced. Prices are holding steady and fairly firm on all grades. Smokeless is holding the advance recently made. All-rail coals are stable, with southern Illinois lump firm at $3.25; Indiana, $3@$3.25; central Illinois, $2.75@$3; western Kentucky, $2@$2.15.

### Southwest Output Still Behind Orders

The impetus given the coal market in the Southwest by the early arrival of freezing weather has carried it briskly through a week of moderate temperature. Kansas mines started last week two weeks behind on deliveries of lump, two days were lost for Armistice Day and pay day, and the week ended with no diminution of unfilled orders. Operators report from three days' to a week's accumulation of orders for Kansas nut. The supply of screenings is about equal to the demand. There have been no changes in prices. While some operators quote as low as $2.25 on screenings on large contracts, $2.35 is the prevailing price.

The demand for Colorado domestic coal continues to increase since cold weather set in. A great many operators are booking orders now for December delivery, which is quite a contrast with this time a year ago. Labor shortage is a disquieting development, but it is hoped that this will be remedied when the sugar beet industry campaign is over, which will release a great many employees who will go back to the coal mines again. There has been no change in prices on Colorado coal during the last week. Raton and Dawson, (N.M.) mines, which produce about 90 per cent of New Mexico coal, announce these new quotations: 6-in. lump, $4.25; fancy egg, $4.25; fancy nut, $3.75; fancy pea, $3.25.

Utah mines are working about two-thirds of full-time capacity. There is a slight shortage of cars, but the situation so far is not such as to hinder the filling of orders. Generally the larger sizes are the stronger. Demand for coal for heating purposes is stronger now that cooler weather has set in. Mines and smelters are the biggest industrial customers, but there is a good demand for steam coal, due to heavy traffic on the railroads. Sugar factories are in the midst of a heavy campaign, and they are providing a good outlet for slack. Prices remain steady and the labor situation is excellent.

### Cincinnati Market Retains Strength

Since the recent price spurt there has been a lull at Cincinnati, but the market is in as strong a position as it was a week ago, perhaps stronger for despite warmer weather, the closing of shipments to the lakes and a promise of 100 per cent car supply to the Louisville & Nashville fields of southeastern Kentucky there have been no drastic breaks in prices. There have been recessions, but only where the demand has moderated.

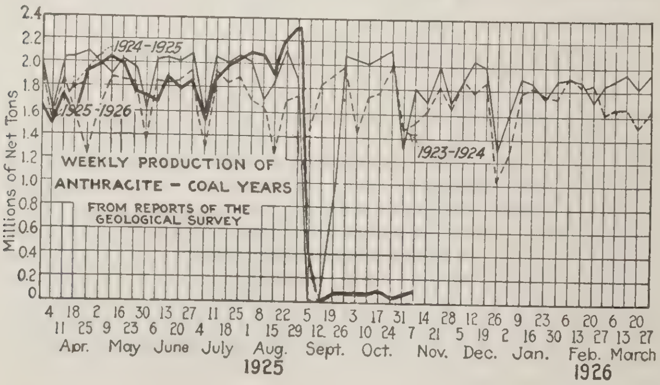
Due to a blockade at the lakes the movement has slowed up, only 13,011 cars being reported by the American Railway Association as passing through the Cincinnati gateways last week, a decrease of 1,964 as compared with the week previous, but 302 more than in the corresponding week of last year. Of these, 2,103 cars were routed to the lakes, a decrease of 770 cars from the previous week but a record movement for the closing of the season.

Most of the high-volatile demand last week was for block (4-in. and 6-in.) sizings. Miller's Creek, Coal Rivers, Elkhorns, the Jellicoes and the like were firm around $4@$4.50. West Virginia offerings range between $3 and $3.50. The Hazard price of $3.25@$3.50 held and Harlans about the same. The make of egg seemed a little more than the market would digest, so from a top of $3 these sizings fell to $2.65@$2.75 and with a slackened demand for mine-run and slack the former reverted to its old position and screenings down to a $1.25 average.

There has not been much adjustment in smokeless, lump still ranging $5@$6, with contract takers getting the better of the argument. Mine-run, which had stiffened a bit, has again struck a dead level of $2.50. Screenings are said to have sold up to $2.25, but considering volume sales the general market has not gone beyond the $2 level.

Heavy rains have given the river a good running stage, and a plentiful supply is coming down for those engaged in this trade. Cincinnati retailers are still fencing with the market with a spread of $9.50@$10.50 on smokeless lump, $6.50@$7 on mine-run, $6.50@7 on bituminous lump and $4.50@$5 on slack.

Warmer weather at Columbus has caused a slight hesitancy in the domestic trade, although the new prices announced Nov. 1 are generally maintained. Retail prices, which jumped several weeks ago, are still firm and little cutting is reported. Because of the big jump in smokeless there is a better demand for splints, as the difference is $2.50 to $2.75 per ton.



The steam trade is quiet and rather spotty. Buying is mostly from hand to mouth, although a tendency to increase reserves is noticeable as to utilities, iron and steel plants and larger manufacturing plants. While car shortage is appearing in certain places, still this is not serious yet.

Production in the southern Ohio field ranges around 30 to 35 per cent of capacity with many large mines in condition to resume work immediately when market conditions warrant.

In eastern Ohio there has been a decided let-up in domestic orders. Pocahontas and other West Virginia and eastern Kentucky lump sizes have weakened 25c. to 50c. per ton f.o.b., Pocahontas lump being quoted at $5.50@$5.75 and the others $3.25@$3.50 f.o.b. mine.

Inquiries and orders from steam consumers also have been comparatively light, but despite this market situation eastern Ohio production during the week ended Nov. 7 was the largest of any week in the present calendar year. A total of 332,000 tons was mined or 23,000 tons over the preceding week and 21,000 tons over the corresponding week a year ago. This larger production is almost entirely moving in the late-season lake trade.

### Eastern Demand Disappears from Pittsburgh

The Pittsburgh district coal market seems quiet since the recent and brief bulge in demand from the East, chiefly for egg coal. For a few days egg coal brought $4.50@$5; even $5.25, according to some accounts. Now it is about $3, while 3-in. lump is now irrgular at $3.25@$3.75.

The general demand for local domestic consumption and for railroad and industrial use has decreased little if at all. In the last few days slack has advanced sharply to $1.30 @$1.40 for steam, against $1.15@$1.25 formerly, while gas slack is quotable at $1.40@$1.50. The upward reaction is attributed partly to ending of the bulge in lump demand.

The straight bituminous market at Buffalo is quiet. Sizes are doing something, but slack is slow of sale and the trade is wondering what will be done with the coal that is now going to the lakes. Shipping to the lakes will be over in two weeks or so and then it is for these mines to shut down or divide the remaining trade with the other mines. Quotations are: $1.60@$1.75 for Fairmont lump, $1.40@$1.50 for mine-run and $1.26@$1.40 for slack; $2.25@$2.50 for Youghiogheny gas lump, $2@$2.25 for Pittsburgh and No. 8 steam lump, $1.30@$1.60 for slack; $1.75@$2 for Allegheny Valley mine-run. Some Youghiogheny special sizes run up as high as $4, mostly for house use, and some special Pittsburgh sizes are $1 or so up for the same trade.

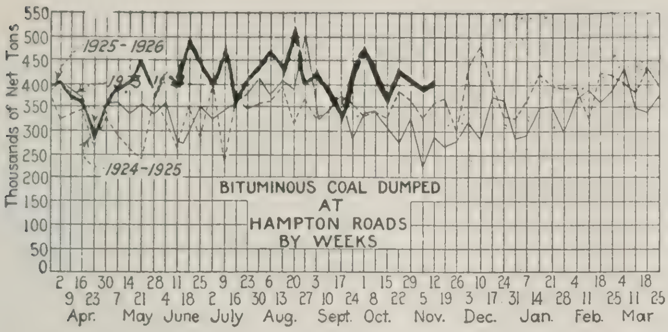
### New England Trade Only Fair

In the New England market the demand for steam coal continues light. In some directions quotations are slightly firmer, but the spot market in general varies from day to day according to the pressure shippers are under to move coal. The relatively few large buyers who enter the market from time to time have now accumulated winter stocks for the most part, and from now on the spot market will be restricted to purchasers of smaller tonnages.

The Hampton Roads agencies have ample supplies available for dumping. About the usual clearances are being applied on contracts, and those factors who take coal for distribution inland are accepting liberal consignments. There is no special push for coal; neither is there any indication that shippers are likely to be seriously pressed for orders. Of course a considerable tonnage of low volatile is being moved in prepared sizes; a modicum is finding its way from the Pocahontas and New River districts all-rail to New England, but the great bulk is moving along the line and to the west in usual channels.

Quotations on lump and egg from the smokeless fields still range $5@$7.50 per net ton at the mines, though a few venturesome sales agents quote $8. No heavy tonnage is being arranged for on the higher prices, but some producers of higher grade low volatile in central Pennsylvania have modified their prices materially during the past week. Good lump and egg can be had at $5.25@$6, these coals taking the minimum Clearfield rate to all New England territory.

For mine-run from central Pennsylvania there is only scattering demand here, and then only in areas well away from tidewater competition of Pocahontas and New River.



Prices on the latter are $6@$6.35 per gross ton on cars Boston and Providence, and only at certain points can all-rail coals find a market at $2.15@$2.50 for fair to good grades.

## Trade Eases in Middle Atlantic Markets

There is not much activity in the New York bituminous coal market outside of mine-run coals. The latter move easily but buyers are not overanxious about future supplies. Screened and prepared coals have eased off in the past week.

Central Pennsylvania low-volatile prepared coals are quoted at $6@$6.50 with lump coals $4@$5, depending on quality and sizing. While Pennsylvania mine-run coals are in healthy condition, prices remain firm at last week's level. Some grades of Pool 1 Pennsylvania coals are offered at $2.50, but the average market is 25c. higher.

Interest in New River and Pocahontas prepared coals was awakened late in the week by the I. C. C. hearing on rates from those fields to this territory. Some of these coals are now coming into this area to take the place of anthracite and efforts are being made to increase their use. Quotations range $6@$7.50.

Receipts at the piers are heavy but the tonnage is easily moved.

Several cargoes of Welsh coals are said to be on their way to this harbor.

The quickening of a week ago in the Philadelphia market has lost much of its force. The market for sized bituminous continues good, but it is in mine-run that most advance has been made. Orders from contract customers are in good to heavy volume, spot buyers also are taking much coal, and the shipper admits that the future is one of much promise. Tide trade is good only in bunkers, as the export trade continues to hang back.

The soft-coal trade at Baltimore has been marking time for the past week in an industrial sense. Extreme activity marks prepared sizes which can be used as substitutes for anthracite, the better grades are still bringing $5.50@$7.50 per ton, f.o.b. mine. Industrial coals continue only in fair demand and there continues an adequate supply. The export situation is entirely dormant.

The steam market is very active at Birmingham and all grades of coal are moving from the mines as promptly as car supply will permit. Spot orders are brisk and shipments against contracts are heavy. Bunker trade is showing more activity than in several months.

The domestic market is much improved over a few weeks back, demand being sufficient to absorb the production of high-grade product promptly, with a little lagging in the movement of lower qualities. Most mine prices are the same as in October, increases of 25c. to 50c being reported for a few operations.

The coke market is active and much of this product is being shipped North, East and West as well as supplying the demand in home territory, which is heavier than in some time. Several additional furnace stacks are soon to be blown in.

Quotations on some of the better grades of coal have advanced 25c. to 50c. a ton in the last week, Cahaba mine-run now ranging $2.25@$2.50; washed, $2.25@$2.75; Black Creek mine-run, $2.25@$2.50; washed, $2.50@$3; Corona mine-run, $2.50; washed, $2.75; Carbon Hill washed, $1.90@$2.25. Foundry grades of coke are quoted for spot shipment $6@$6.50; egg sizes, $4.50; nut, $4.25 per ton ovens.

Car supply on all lines has been short of requirements at some time during the past week, causing interruptions at quite a number of operations.

## Hard-Coal Substitutes Continue to Drag

Although anthracite is practically out of the New York wholesale market consumers in the metropolitan district have not taken to buying the various substitutes as it was expected they would. Retailers have some hard coal in their yards but they are distributing it among regular customers in small lots. These coals consist mostly of pea and buckwheat.

Indications are that the demand for substitutes will depend entirely on weather conditions, but thus far the retailers have not had a demand to justify filling their bins with substitute fuels.

The call for coke has flattened and quotations are now about $2 below what they were ten days ago. Beehive product is quoted at $7.50@$8.50, and run-of-oven $6.50@$7.

The tidewater market continues to hold some pea and buckwheat coals for those willing to pay the prices quoted. Independent pea coal was offered during the latter part of the week at $17 alongside and independent buckwheat at $8.

A lull in the trade developed in Philadelphia last week and consumers displayed little interest in buying. Quite a few dealers with fair stocks of pea are easily getting $15 a ton for it, and the sale of buckwheat is much improved at $9@$10.

Company pea shipments are fast reaching an end, and the company shipping buckwheat is declining further orders.

The slowing-down in retail demand has caused a decline in the price of coke at the ovens, some breaks being as much as $1.50 a ton.

The situation at Baltimore is summarized in the statement that there is no reserve except limited quantities of pea and buckwheat in a few of the yards. What hard coal is left is being distributed in one- and two-ton lots on emergency orders. Dealers are purchasing substitutes, such as soft coal and the so-called anthracite briquets. The latter in most cases are selling around $13.50, without discount, for a 2,000-lb. ton. Since Sept. 1 the records of the fire department show that 176 applications for oil-burning installations have been approved.

At Buffalo pea and buckwheat are giving out. Though the demand for coke at prices up from $6 to $10 a ton for a while exceeded the supply, it is running down now and it is carrying the prices with it. Some coke manufacturers have reduced prices $5 or so and still the jobbers are afraid of it, for they say it is quite possible for the price to come down several dollars more any day.

## Connellsville Coke Market Liquidates

The past week has been one of liquidation in the Connellsville coke market. At the end of last week there was a considerable accumulation of loaded coke on track, and the railroads, with possibilities of a car shortage, would not allow it to remain. Whereas three weeks ago the market range was $8.50@$9, sales in the last few days have centered around $6.

The decline stimulated buying somewhat in the East and induced a little blast-furnace buying for reserves, as with contracts at around $3 and such fancy spot-market prices the operators have not shipped any more to blast furnaces than contracts absolutely required.

The accumulation is pretty well worked off, but as recent sales were for quite prompt shipment many operators are now practically without a backlog. With such heavy production coke may be forced on the market next week. There is quite a general prediction, however, that when the market does begin to turn upward it will move apace, for Eastern requirements should easily absorb all the coke the region can furnish and much higher prices than $6 could easily be paid.

Foundry coke has softened and is now quotable at $7@$7.50, with a moderate running demand.

## Car Loadings, Surplusages and Shortages

# Foreign Market And Export News

## Inquiry Gains Steadily In British Coal Market; Receives U. S. Orders

Though the situation in the Welsh steam coal trade shows improvement, it has not made the progress hoped for. New orders have been received to a substantial extent, but business is still fully 25 per cent below the volume necessary to give full employment at the collieries. In addition, orders are very unequally distributed, as revealed by the great contrast between the activity of the anthracite collieries in the western area and the inactivity of the semi-bituminous pits of Monmouthshire, where the acute depression has not been relieved. Improvement has been retarded by a shortage of steamers lately, due to delays occasioned by a prolonged period of stormy weather.

Some business is coming to South Wales from the United States as the result of the anthracite strike in that country. Dry nuts in particular are strong, but the supply is limited. Generally, colliery owners are better booked over November.

The improvement in the Newcastle-on-Tyne coal trade is fully maintained, inquiry being unabated for Northumberland and Durham coals, but there is a limit to the capacity of the pits to provide supplies for prompt loading, and in consequence a good deal of trade is being carried over. Business done recently includes cargoes of coal and coke for Canada and the United States as well as increased consignments to South America. Inquiry for delivery up to the end of the year and to next March is growing and bunkering and other contracts for next year are begining to command attention. There is an improving market for Durham coking coals. Coke is particularly active and strong. Stocks throughout the district are meager, while the demand is brisk for months ahead.

Output by British collieries during the week ended Oct. 31, according to a special cable to *Coal Age*, totaled 4,835,000 gross tons, compared with 4,820,000 tons in the preceding week.

---

## French Dealers Renew Stocks When Demand Lags

In the French Coal Market industrial coals are in light demand and there is no talk of replenishing stocks. The continued rise of the pound and the Belgian franc is hampering imported coals, Belgian coals being further handicapped by an advance in the Charleroi-Paris freight rate.

Domestic coal consumption has been slow, and coal merchants have been refilling their yards which were understocked owing to delays in shipment from Belgian and French mines.

There still is some irregularity in the return of empty wagons to the mines, but barges are more plentiful.

Receipts of indemnity fuels from the Ruhr during the first seventeen days of October, included 239,400 tons of coal, 132,400 tons of coke and 18,000 tons of lignite briquets. Beginning Nov. 1 prices of anthracite dry and semi-bituminous sized were increased 10 fr. and of lignite briquets 5 fr.

During the first twenty-seven days of October the O. R. C. A. received from the Ruhr 196,735 tons of reparation coke.

## Firmer Tone Brightens Outlook At Hampton Roads

Business at Hampton Roads was better last week with coastwise and bunker trade improving and inland business showing considerably greater strength. The new all-rail freight rate to New York and New England had strengthened prices in domestic trade, and inland consumers were paying a premium.

Inquiries were better and demand, except for foreign movement, was showing a substantial increase. Foreign shipments were slack, but regarded as normal for this time of the year. The tone of the market was strong and the outlook considerably brighter.

## Firmer Note in Belgian Market

There has been no particular change in the situation in the Belgian coal market. In spite of the remarkable decline of the French franc, there is no considerable competition by collieries of the Nord and Pas de Calais, due to the low prices quoted by Belgian mines in the Borinage basin. On the other hand, British competition is even stronger. If, as is hoped, the Charleroi strike were to come to an end, there would certainly be an increase of demand from this direction.

Prices for industrial coals seem to be firmer, except for heavy tonnages, on which concessions are still the rule of the day. In domestic coals the tendency is still toward firmness, though the weather has not been favorable to consumption. Delays in transportation have been so persistent, however, that the mines hardly notice the diminution of consumption. There is no anthracite for disposal. Coke is slightly improved and for briquets prices are somewhat firmer owing to the high cost of pitch.

Receipts by Belgium of indemnity fuels from the Ruhr during the first nine months of 1925 totaled 1,870,000 tons.

# News Items From Field and Trade

## ALABAMA

The Birmingham district had as its guests during the week ending Nov. 14 J. W. Paul, chief coal mining engineer of the Bureau of Mines, Pittsburgh; R. R. Sayer, chief surgeon, Washington, and M. Van Siclen, engineer in charge of mining research work, Washington. These men are making a ten-days inspection and survey of the coal mines of the district. The tour will be directed by officials of the Birmingham office of the Bureau of Mines, J. E. Cash, W. R. Crane and F. E. Meriweather. The work of the Birmingham section of the Bureau for the coming year will be mapped out by the visiting officials. The visitors will be the guests of the Alabama Mining Institute at a safety meeting at the Overton mines of the Alabama Fuel & Iron Co. during their stay here.

The brisk coke market has brought about a resumption of several hundred beehive ovens, 200 being placed in commission by the Sloss-Sheffield Steel & Iron Co. at Flat Top and also a number in the batteries of the New Castle Coal Co., at New Castle.

Walter E. Henley, president of the Little Cahaba Coal Co., of Piper, and the Blocton-Cahaba Coal Co., Coleanor, has been elected president of the Birmingham Trust & Savings Bank, one of the oldest and the second largest financial institution in Alabama, succeeding the late Tom O. Smith.

The Connellsville Mine of the Yolande Coal & Coke Co., near Yolande, Tuscaloosa County, which has been in process of rehabilitation for several months, is expected to be producing coal soon after New Years. This opening had been idle for some fifteen years or longer and had to be pumped out and provided with new equipment both inside and out and the necessary tipple structures and washery.

## ARKANSAS

The No. 2 mine of the Western Coal Mining Co., at Deming, will be reopened after having been closed for a year. A new tipple is being built at the mine.

Of the 192 coal mines listed in Arkansas, 94 were in operation at some time during the fiscal year ending June 30, 1925, and their total output was 1,398,346 net tons, an increase over 1924 of 99,555 tons, according to the annual report just published by Claude Speegle, state mine inspector. Fifty-three mines were idle last year and 49 were abandoned. The total number of men employed in and around the mines was 3,701. The number of non-fatal accidents was 39 and fatal accidents numbered 10.

## COLORADO

Charles W. Brown, formerly general sales agent of the Hayden Brothers Coal Corporation, operating mines in Routt County, has been appointed general manager, to fill the vacancy created by the death of L. A. Hayden.

About 160 employees of the Pikeview mine, four miles north of Colorado Springs, refused to return to work Nov. 9, demanding an immediate raise in wages from $5.25 to $5.82 per day. The mine is owned by the Pike's Peak Coal Co., an E. A. Carlton interest, the largest coal mining company operating in the district.

## ILLINOIS

The Galesburg Mining Co., Galesburg, which is mining coal from a new mine five miles east of that city, is now sinking a large air and escapement shaft, 6¾ x 10½ ft., located 500 ft. east of the present shaft. This mine is now sending from 80 to 100 tons of coal daily to the top and the bed is 4 ft. to 4½ ft. thick. The tipple has been completed and is doing excellent work.

Rice Miller and Judge Amos Miller, his father, have purchased the mine and other property of the Hillsboro Coal Co. at Hillsboro. The deal is said to have involved $100,000. Rice Miller had been superintendent of the Hillsboro Coal Co. for many years. He also is president of the Illinois Coal Operators Association. The mine employs several hundred men and has been a steady producer for a number of years.

## INDIANA

Mine No. 1 of the Sargeant Coal Co., near Newburg, has resumed work after a long idleness. The Schimmel-Hampton Coal Co., of Newburg, is operating the mine with a force of 50 men.

As a result of miners of Dering mine No. 6, in the Clinton field, refusing to work because of an injunction restraining Albert C. Daily, state mine inspector, from closing the mine, officials of the company on Nov. 10 asked for a conference with the miners and the state mine inspection department. The injunction was issued in the Circuit Court at Rockville. The conference probably will be granted, according to union officials, who deplored interference with the department carrying out its lawful duties. These officials said the effects of such a ruling might establish a precedent actually courting violation of the established laws protecting the health and safety of the miners.

A loss of $75,000 was suffered Oct. 28 by the Maumee Collieries Co., owners of the Oak Grove Mine, near Sullivan, when the tipple burned to the ground. Fire departments from surrounding cities saved the other buildings.

All records for coal production in the older mines of Indiana were broken recently when the Twin mine, owned and operated by the Linton Summit Coal Co., at Linton, hoisted and loaded in eight hours a total of 3,054 tons of coal. This mine was sunk back in 1902 and miles upon miles of coal have been loaded from the mine, but not in its history, or the history of any of the other first mines of the state, has such an eight-hour production been recorded. The mine employs about 400 men.

Somerville Mine No. 1, Somerville, was damaged to the extent of $50,000 Nov. 3, when fire destroyed the tipple. Defective wiring in the weighroom is blamed for the fire. Clem J. Richards, Terre Haute, president of the General Fuel Corporation, owner of the mine, has announced that work on rebuilding the plant will be begun at once. According to Mr. Richards, the mine was working at capacity at the time of the fire, producing an average of 2,500 tons a day, with 300 men employed. He said that operations probably would be resumed within two months.

## IOWA

Negotiations are still in progress for the amalgamation of several of the larger mining concerns of Polk County. Representatives of the Norwood-White, Pershing, Shuler and Scandia companies have been in session, but it was stated following the meeting that completion of the merger is still some distance in the future.

## KANSAS

The international United Mine Workers' commission which recently, at the behest of President Lewis, settled the supply strikes in five southeastern Kansas mines, will return soon to investigate a dispute which followed the return to work of striking miners at the Western Coal & Mining Co.'s mine No. 21, operated by Fern & Lyons. The operators fined the men $1 a day each for the five days they were on strike.

## KENTUCKY

Justin Potter, of the Nashville Coal Co., producers, jobbers and sales agents for mines, rode to Louisville on Nov. 10, from Nashville, Tenn., driving his own airplane in 1 hr. 30 min., returning the following day after a visit to the company's local office. Potter was an army aviator at Kelly Field, San Antonio, Texas, during the war and recently bought a plane for quick service between Nashville, the offices in Louisville and mines in the western part of Kentucky.

The West Kentucky Coal Co., of Sturgis, the largest company in the western Kentucky field, with about twenty-five mines, has moved sixteen barges of coal of 600 tons each from Caseyville, south. This was the first river movement that the company has made in several months, due to low boating stages. The coal will be delivered at Memphis, Vicksburg and Greenville, on the Mississippi River.

C. E. Reed, secretary of the West Kentucky Coal Bureau, Louisville, was recently elected treasurer of the Louisville Lion's Club at its annual election.

After being out of the Middlesboro field as a coal buyer for about two years the Southern Railway Co. is again buying coal in that section and is reported to be drawing about thirty cars a day. This company appeared to have a falling out with the Louisville & Nashville R.R. over a rate on hauling coal over L. & N. tracks to its own lines and quit the field.

The Virginia Harlan Coal Corporation, Walter W. Liddle, secretary-treasurer, announces the removal of its main offices from Pineville to the mines located at Whipple, Kentucky; post office address, Balkan, Bell County.

## MARYLAND

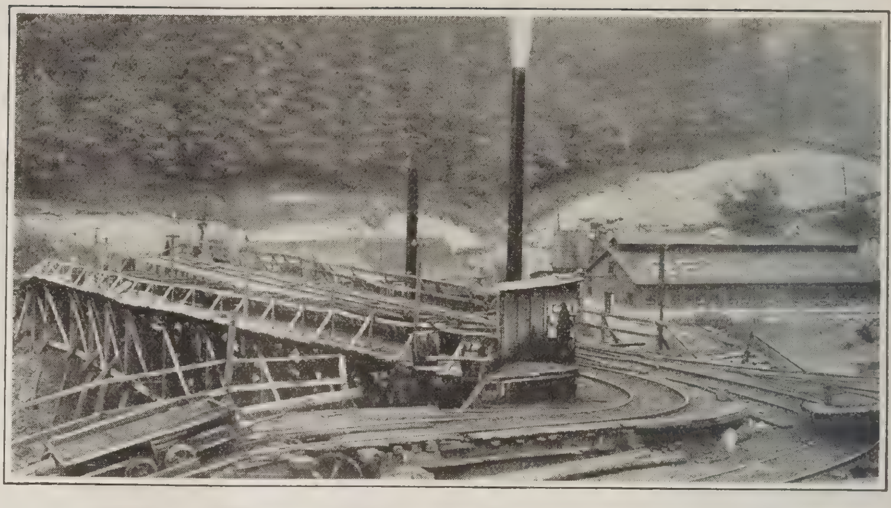
Ocean mine of the Consolidation Coal Co., at Midland, at one time known as the largest bituminous mine in the world, has started to operate after a shutdown of two years. A force is on the outside rebuilding the tracks and a force inside is laying rails a distance of over two miles from the mouth of the slope. As the new road is laid the shipping of coal will be started and a hundred or more men will be employed. The whole plant, inside and out, will be operated by electricity.

## MINNESOTA

The City Purchasing Agent of Minneapolis is taking bids until 3 p.m. Nov. 25 for furnishing for the Board of Education 18,200 tons of coal. A certified check for 3 per cent must accompany bids.

## NEW YORK

The Buffalo Chamber of Commerce has passed a resolution urging that the present controversy between coal operators and miners be permitted to go to its natural conclusion, so that an artificial increase in the cost of anthracite may not result from interference, as has been the case in previous strikes.



**Rex No. 1 Mine, La Follette Coal & Iron Co., La Follette, Tenn.**

Trips pulled out through the slope, cross the trestle, then descend on the track, seen to the left in the picture, to the tipple, which is located several hundred feet down the hollow. The smokestacks are on a small boiler plant which supplies steam for the bath house and to operate the slope hoist. The bath house is the building with the "Rex Coal" sign on the roof. At the present time the production of 600 tons of coal per day from the Rex No. 1 mine is about the only activity of the La Follette Coal & Iron Co. The beehive coke ovens and blast furnace have been down for some time. J. E. Hendren is general superintendent of the three coal mines owned by the company.

## OHIO

The Plum Run Mine of the United States Coal Co., at Bridgeport, resumed operations Nov. 12 after having been idle since spring. It employs 1,225 men when running full.

Lee Lewellyn, general manager of the Houston Coal Co., Cincinnati, resigned his position effective Jan. 1, 1926, when he will return to the Pittsburgh Coal Washer Co., of Pittsburgh, Pa.; one of the leading concerns engaged in designing, manufacturing and installing coal-handling and coal-preparing plants of all kinds. Mr. Lewellyn has been with the Houston Coal Co. for the past two years.

The Ohio district of the United Mine Workers declares that it has been appealed to in an effort to help solve the financial crisis that marked the attempt to operate the Goat Hill mine, at Amsterdam, Jefferson County, on a co-operative basis. It was said $60,000 was needed. The union said it would have nothing to do with the operation.

Dumpings on the Hocking Valley Ry. docks at Toledo for the week ending Nov. 11 were 235,553 tons, which is a record for a week at this season. During the month up to the 11th the dumpings were 380,848 tons. During the season up to Nov. 11 the docks handled 7,655,318 tons, as compared with 6,140,636 tons during the corresponding period last year.

In the hearing before Justice M. L. Shores of the claim of 218 miners employed by the Cleveland & Western Coal Co., at the Franklin mine, in Belmont County, who sued for wages aggregating about $14,000, a decision was rendered for the plaintiffs. The miners sued for the wages after the operating company had sued the men for damages caused by an unauthorized strike. The decision will be appealed by the company.

## OKLAHOMA

Tom Lidell, Robert Stenhouse, William Croy and Earl Franklin, all striking union miners, whose actions were held directly responsible for the sending of state troops into the coal fields of the Henryetta (Okla.) mine district last June, were acquitted Nov. 9 for the second time of the charge of rioting, according to word received from Okmulgee. The charge was made following a fight between Lidell and Andy Meitus, working as a non-union miner for the Crowe Coal Co. Meitus was admitted to citizenship last week. In the trial it was brought out that he had lived at Henryetta twenty years before applying for naturalization papers.

Osage Mine No. 5, at Krebs, has opened for work with a fair-sized force of workmen. The mine is one of several in this field which have opened up on the 1917 scale since the decision of Federal Judge R. L. Williams prohibiting the presence of large forces of pickets at mine entrances. This mine had been closed since the general strike in District 21, called on Sept. 1 by William Dalrymple, district president of the United Mine Workers.

## PENNSYLVANIA

President Calloway of the Buffalo & Susquehanna Coal Co. last week addressed a letter to the company's striking miners at DuBois, calling on them to go to work and promising them full union wages till existing contracts are filled, if they would resume work on or before Nov. 16.

Pickands, Mather & Co., of Cleveland and Buffalo, have completed a coke plant at Erie, and have 50 ovens already in operation.

The McDonald Coal Co., a Pittsburgh corporation, is held by Federal Judge F. P. Schoonmaker to have no claim against the internal revenue department for $82,255.13, return of which was sought by the coal company for excess income tax. The judge said the company had not filed a waiver as required by law. He also decided there was not sufficient evidence.

The opening of the mines of the Buffalo & Susquehanna Coal Co. at Sagamore, under a lease to the Sutter-Rinn Coal Co., is held to be a violation of agreement and the union miners have entered a protest against it. They have also undertaken to stop the eviction of union miners from company houses which may be wanted for new miners.

The Northwestern Mining Co.'s operations of the Dagus (Erie) mines, which have been suspended since Sept. 1, have resumed operations with a force of 500 men.

John C. Graham, of Butler, has sold 500 acres of coal land in Sligo Borough and Toby township to the Standard Coal & Coke Corporation, Chicago, for about $75,000. The purchasers have extensive mines in half a dozen states and are supposed to be preparing to enter the Eastern trade in a large way at an early date. Heavy equipment outlays are expected to be made soon.

After a shutdown for more than six months, the Sonman shaft mine at Portage, operated by the Sonman Shaft Coal Co., has resumed operations. This mine is working under the Jacksonville scale and employs about 150 men.

For a consideration of $650,000, the Elk Hill Coal & Iron Co., a subsidiary of the Scranton Coal Co., has acquired the Mount Pleasant colliery in Scranton from Mrs. Kate Pettibone Dickson, of Wilkes-Barre, widow of Alan Dickson, a native of Philadelphia. The sale is covered by a mortgage, payable within one year. The sale involves the transfer of 227 acres of coal land and 96 acres of surface property, including the site of the Mount Pleasant breaker. For a number of years the property has been operated by the Elk Hill company on a lease from Mrs. Dickson. The property has been in the hands of the Pettibone family for almost seventy-five years. Mrs. Dickson is the sole survivor of Payne Pettibone, who made his home in Wyoming, Pa.

Loadings in the central Pennsylvania coal district approximated 72,000 cars in October, the maximum for this year, against 67,000 in October last year. According to reports from Altoona, 100 idle mines in that district have resumed operations this fall. Much of the demand is for prepared sizes for New England states.

The new tipple at the Ella mine of the Hillman Coal & Coke Co., on the Monongahela River, near Pittsburgh, has been completed.

Bituminous coal (revenue) transported by the Reading Company during September, 1925, totaled 1,748,985 gross tons, compared with 1,404,233 tons in the corresponding month of last year.

Boiler houses of the Lehigh Valley R.R. at different shops along the system have been using culm for fuel during the past few weeks. Boiler rooms at many of the breakers and mines also have been burning culm since the strike got under way.

The Meadowbrook Coal Co., at Dunmore, which is owned by Scranton men, is making extensive improvements to its properties so that when the mine suspension ends everything will be in readiness to produce the maximum amount of coal. Last May the company purchased the John J. Boland Coal Co.'s interests in Dunmore. Recently the same concern tried to buy the Kearney & Brown operation at Dunmore but when officials of that firm declined to sell outright arrangements were made whereby the property was taken over on a lease. Two score of men have been employed in making repairs to the property. These include the construction of a large concrete pit where coal from the mines will be dumped after being run through the rollers and crushed to the necessary sizes. After the coal has been prepared it will be carried by conveyor lines to the breaker, where it will pass through the chutes for distribution to the coal pockets.

**Soft Drink Stand, Edgewater, Ala.**

During the last few years, particularly since the advent of national prohibition, the consumption of ice cream and soft drinks has increased tremendously. In some mining towns the commissary or drug store are the points where the populace seeks to quench its thirst. At Edgewater, however, the Tennessee Coal, Iron & R.R. Co. has erected this attractive brick building for the express purpose of dispensing soft drinks and commodities or necessities of a similar nature.

The H. C. Frick Coke Co. has fired the Dorothy plant in the Latrobe district. The plant is now being electrified, but resumption of the mine will not interfere with these improvements.

J. B. Nessle, once general coal and ore agent, New York Central lines, has been made traffic manager of the Pittsburgh & Lake Erie R.R.

The "horseshoe" of the old D. & H. gravity railroad, near Seeleyville, in Wayne County, is again the scene of much activity after being idle for years. There are enormous piles of culm near this place since the old railroad was abandoned and Sweeney Bros., of Scranton, are now engaged in removing the coal to railroad cars for shipment to a concern in New York State. This firm is said to have obtained rights to the culm reserves two years ago and has been holding them in case need for fuel developed in an emergency. It was necessary to cut through a hill and lay a track almost a half a mile long so that two steam shovels could load the cars. It is estimated that nearly a million tons of culm will be taken from the dumps before the supply becomes exhausted.

To facilitate the unloading of coal and coke supplies from upriver points, the Weirton Steel Co., Weirton, W. Va., on the Ohio River, has given a $750,000 contract for the construction of a concrete dock with loading and unloading apparatus. It will be completed by next summer.

Governor Pinchot has appointed John J. McCall, of Shamokin, as a member of the anthracite mine inspectors' examining board.

The Chartiers Creek Coal Co., one of the largest independent coal companies in Washington County, resumed operations Nov. 16 at its East End Mine, near Canonsburg, after several months' idleness. The Jacksonville wage scale will be paid, it is said.

Suit has been filed in U. S. Court by the Berwind White Coal Mining Co. against the government for the recovery of more than a million dollars. The company claims the money is due for soft coal sequestered by the President during the world war for the use of the navy. According to the company the government took 184,746 tons of coal for which the navy fixed compensation at $740,000. The Berwind White company demanded $1,591,580 for the fuel, basing its claim on the existing value for export coal. The navy paid 75 per cent of the amount fixed by the government and left the matter open for final determination by the courts.

The coal tipple at Reitz No. 3 mine, owned by the Reitz Coal Co., near Johnstown, was destroyed by fire during the past week. The blaze was mysterious, as there was no one about the mine at the time.

Approval of the merger of the Armerford Coal Mining Co. and the Margaret Coal Mining Co., both operating in Indiana County, has been announced by the Bureau of Corporations at Harrisburg. Capital stock of the merged companies, which will be known as the Armerford-Margaret Coal Co., is $260,000. The principal office is in Pittsburgh. D. E. Thompson, Blairsville, is president; D. R. Tomb, Indiana, secretary, and C. F. Armstrong, Leechburg, treasurer.

John F. Irwin, a coal operator of Latrobe, bought from the First National Bank of Pittsburgh the dismantled Baggaley coal plant in the Latrobe district without the company houses. He started immediately to prepare the plant for coke making. Although the greater part of the coal at the old Baggaley mine has been taken out, a large quantity remains in the headings and in portions of the mine lost through falls. This will be reclaimed by stripping. The purchase includes 370 ovens, of which 100 are being fired.

The Snowdon Coke Co. has begun the erection of a steel 3-track tipple and steel trestle approach at the Mt. Hope Mine, at Linn, Fayette County. The tipple will be equipped with shaker screens, picking tables and loading booms and it will be possible to produce lump, nut and slack or any combination thereof. The foundation is nearly finished and the plant is expected to be completed next spring. Heretofore this plant has shipped coke exclusively.

The Republic Iron & Steel Co. has resumed full operation at the Republic Mine, in the Connellsville region, after more than a year's idleness. Two hundred and fifty ovens have been blown in.

## UTAH

The Public Utilities' Commission has granted the Utah Railway Co. permission to purchase the line, nearing completion, of the National Coal Railway Co. The new line is a few miles long and is being constructed for the purpose of developing new coal properties owned by five companies, all of Salt Lake City.

Three miners were killed by falling coal in Carbon County mines during the week-end of Nov. 1.

The federal government is contesting the right of the state to sell a section to which the state gave deed on July 3, 1905. The land in question is a section just off Huntington Canyon in Emery County. The land was sold at a private sale to Henry C. Lund in January, 1902. It sold at $2 an acre and the mineral rights were not reserved. In June, 1902, the contract to purchase the land—the sale was by time payments—was transferred to P. J. Quealy of Kemmerer, Wyo., prominent coal operator. Mr. Quealy received his patent in July, 1905. The federal government claims that it was known at the time of the sale that the land was of mineral character and, therefore, should not have been sold.

## VIRGINIA

The tipple of the Empire Collieries Co., at Pulaski, was burned Sunday afternoon, Nov. 8, entailing a loss of $60,000. The fire is believed to have started from defective electric wiring. As a new tipple and breaker have nearly been completed at the mines, operations will be interrupted only about three weeks. It is understood the destroyed tipple will not be rebuilt.

## WASHINGTON

The California-Alaska Corporation expects to spend $500,000 immediately in reopening and developing the Snoqualmie coal mine, situated twenty-four miles from Seattle. The property is owned by Charles B. Niblock, of Seattle, and embraces about 2,000 acres. The California-Alaska Corporation has a 99-year lease on the property. Development was begun before the World War by the Western Coke & Collieries Co., but the war plunged the company into financial difficuties, it was said, and the promoting head died, and development was halted after approximately $300,000 had been spent. It is expected that the mine will produce 2,000 tons of coal a day within the next ten months. There are forty-five coke ovens on the ground, which will be increased to fifty, and $150,000 will be spent in installing a coal washing plant.

## WEST VIRGINIA

The Crab Orchard Improvement Co. is making improvements on an extensive scale at its mines at Eccles, in the New River field, as a result of which it will be able to increase the number of its employees and produce more coal. Much additional equipment is being installed including 400 mine cars, 11 gathering locomotives, 2 mining machines and 1 motor generator set. The No. 6 tipple also is being equipped with shaker screens for preparing domestic coals. It will be necessary to engage about 75 additional loaders and a proportionate number of other employees.

A. B. Rawn, for many years identified with the coal business of southern West Virginia, has severed his connection with the Kingston-Pocahontas Coal Co., of which he was vice-president and general manager, to assume the active management of the Wilson Sand & Supply Co. Mr. Rawn has acquired the interests of Charles R. Wilson in that company, the transfer involving approximately $600,000, it is stated.

Six new coal companies with an aggregate capital stock of $425,000 were formed in West Virginia in September: The Vermillion Coal Co., of Orgas, capitalized at $25,000; Poca-Pack Coal Co., Bramwell, $200,000; Fort Branch Collieries Co., Logan, $50,000; Harman Thacker Coal Co. Williamson, $25,000; Columbus Darby Coal Co., Keith, 1,000 shares of no par value; the Logan Block Coal Co., Huntington, $125,000. The Brown Coal Co. has increased its capital stock from $125,000 to $300,000, and the Bentree Coal & Oil Co. has increased its capital stock from $50,000 to $100,000. Permission has been granted to the Blue Ash Coal Co., of which Charles Litkowski is secretary, at Cincinnati, Ohio, to transact business in West Virginia.

The Carnegie Coal Company has been given five more days to answer the equity suit filed by Harry F. Sinclair, the oil man of New York, in which he is asking to recover $125,000 and have the temporary receivers of the coal company removed. The answer was to have been filed on Thursday.

The tipple of the J. P. Keeley Coal Co.'s Whiteman mine, near Wilsonburg, was destroyed in an incendiary fire on Nov. 11. The loss is several thousand dollars. The mine was nonunion.

The Sitnek Coal Mining Co. has erected a new wooden tipple with a steel frame at Katherine mine, near Lumberport, Harrison County, equipped with loading booms and picking tables. The tipple has a capacity of 1,500 tons daily.

## WYOMING

The Gunn-Quealey Coal Co. is prospecting its Sweetwater vein, in the Rock Springs district with diamond drills, testing the area and depth. At present one of the outfits is drilling a short distance northwest of the Quealey (Sweetwater) properties of this company.

## CANADA

The commission appointed to investigate the coal industry of Nova Scotia inspected the collieries of the New Waterford district last week and also made an examination of the housing and living conditions of the miners. On Nov. 10 they inspected the coal piers at Sydney and Louisburg to ascertain the shipping facilities of the British Empire Steel Corporation. The first public session of the commission for the hearing of evidence was held in the Court House at Sydney Nov. 11, the first part of the sitting being occupied with the reading of a brief prescribing the case of the miners.

## Obituary

**William J. Wickes**, 63, organizer of many industrial concerns in Saginaw, Mich., and one of the best known manufacturing men in Michigan, died Nov. 1 of heart trouble in New York City, where for the last two years he had been directing the affairs of the Wickes Boiler Co. and other enterprises in which he was interested. At the time of his death he was president of that company, treasurer of the Wickes Brothers, president of the Consolidated Coal Co., and the United States Graphite Co., director and vice-president of the Bank of Saginaw, vice-president of the Eastwood Plate Glass Co., a director of the Ruggles Truck Co. and was interested in many other concerns. He was a pioneer in the development of the coal districts in the Saginaw Valley. During the war he was chairman of the board of directors of the Saginaw Shipbuilding Co., which turned out many ships. He leaves his wife, three sons, three daughters and one brother, Harry T. Wickes, of Pasadena, Calif.

**Charles A. Fagan**, well-known Pittsburgh lawyer, died at his home last week. He was a director of the Anthracite Coal Co. of Wilkes-Barre, the Logansport Coal Co. and the Gracement Coal Co.

## Coming Meetings

**West Virginia Coal Mining Institute.** Fall meeting, Nov. 24 and 25 at the Hotel Morgan, Morgantown, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

**American Society of Mechanical Engineers.** Annual meeting at New York City, Nov. 30-Dec. 3. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**Fourth National Exposition of Power and Mechanical Engineering.** Nov. 30 to Dec. 5, at Grand Central Palace, New York City.

**Coal Mining Institute of America.** Annual meeting, Dec. 9-11, Pittsburgh, Pa. Secretary, H. D. Mason, Jr., P. O. Box 604, Ebensburg, Pa.

**American Mining Congress.** Twenty-eighth annual convention, Dec. 9-11, Washington, D. C. Secretary, J. F. Callbreath, Munsey Bldg., Washington, D. C.

## Recent Patents

**Mining and Loading Machine**; 1,549,699. Walter J. Wilson, Sewickley, Pa. Aug. 11, 1925. Filed Dec. 19, 1921; serial No. 523,451.

## New Companies

**The L. H. & W. Coal Co.**, Henderson, Ky., capital $28,000, has been chartered by Henry and U. M. Gager and Harry B. Jennings.

**The Spavinaw Mining & Coal Co.**, of Tulsa, Okla., with a capital of $15,000, has been incorporated. The incorporators are Asbery Burkhead and J. H. Callahan, both of Tulsa, and J. M. Ramey, of Verdigris.

**The Prospect Park Coal Co.**, 3702 West Main Street, Belleville, Ill., was incorporated Nov. 1 with capital of $9,600 to mine and sell coal. The incorporators are Henry Lilburn, E. J. Bryant and William Van Hoose.

**The Saline River Coal Co.**, Equality, Ill., has been incorporated with capital of $75,000 to mine and produce coal and manufacture all byproducts of coal. The incorporators are Charles H. Guard, Genevieve Guard and George C. Guard.

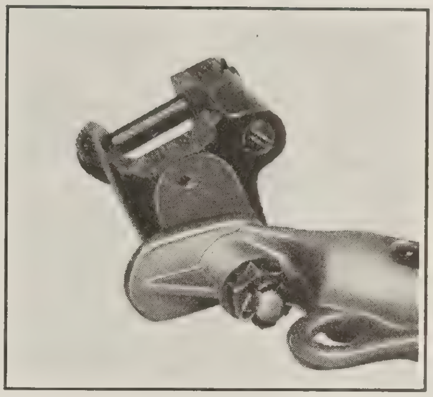
**The Tip Top Coal Mining Co.**, Portsmouth, Ohio, has been chartered with an authorized capital of $100,000 to mine and sell coal. Incorporators are B. F. Vincent, H. C. Stalder, Ruby Praither, Alice V. Arganbright and Joseph T. Micklethwait.

# New Equipment

## Trolley Harp Has Grease Reservoir on Side

Geo. L. Birch, chief electrician of the Southern Mining Co., Balkan, Ky., has patented and is marketing the self-lubricating trolley harp shown in the accompanying illustration. One side of the harp contains a grease chamber. This communicates with a duct which leads through the axle, to the bearing. The chamber is formed by a tapped, ⅝-in. hole which is capped at the bottom by a slotted-head, screw plug.

One filling of the grease chamber is sufficient to lubricate the trolley wheel for several days. It is intended that at regular intervals, the motorman should give the screw plug a turn in order to force a supply of grease into the axle from which position it tends to feed gradually to the bearing. The bottom of the harp is fitted with a wearing plate which can be renewed at small cost. This device, known as the "Birch Self-Lubricating Trolley Harp," fits any standard pole socket, as illustrated. It is manufactured for Mr. Birch by the W. J. Savage Co., Inc., of Knoxville, Tenn.



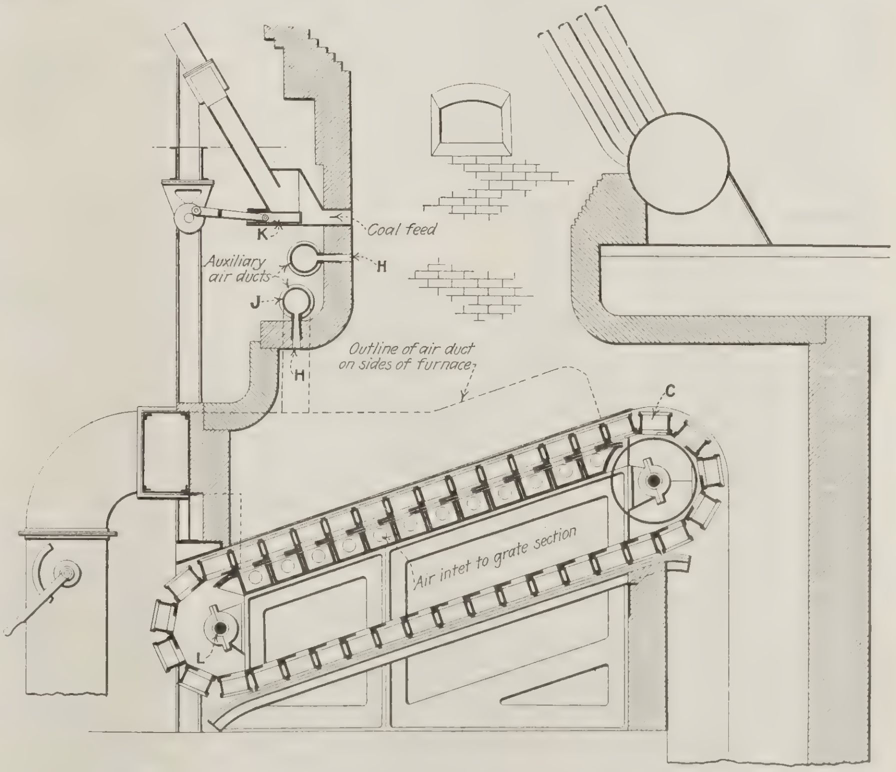
**Grease Enters Through the Axle**

One filling of the reservoir with grease will lubricate the trolley wheel for several days. At intervals depending on the service, the screw plug should be given a few turns to force the lubricant up into the axle.

## Small-Sized Anthracite Is Stoked by Spreading

Utilization of the small anthracite sizes has always represented a problem not only to the mine but to industrial plants as well. Recently Albin A. Norrman and Alfred E. M. Shafer, of Tamaqua, Pa., have developed a stoker for burning these small sizes. As may be seen in the accompanying illustration, this utilizes both the principles of the chain grate and that of spreading, which is the ordinary method by which anthracite is fired by hand.

This stoker known as the "Turbu-



K
Coal feed
Auxiliary air ducts
H
J
H
Outline of air duct on sides of furnace
Y
C
Air inlet to grate section
L

**Fig. 1—Cross Section Through Turbulator and Furnace**

Hollow grate bars extend entirely across the furnace. These are linked together forming a forced-draft, chain grate that is inclined against the direction of travel. Coal is fed through the front furnace wall and falls upon the grate near its middle. Much of the fuel is ignited by the time it reaches the grate.

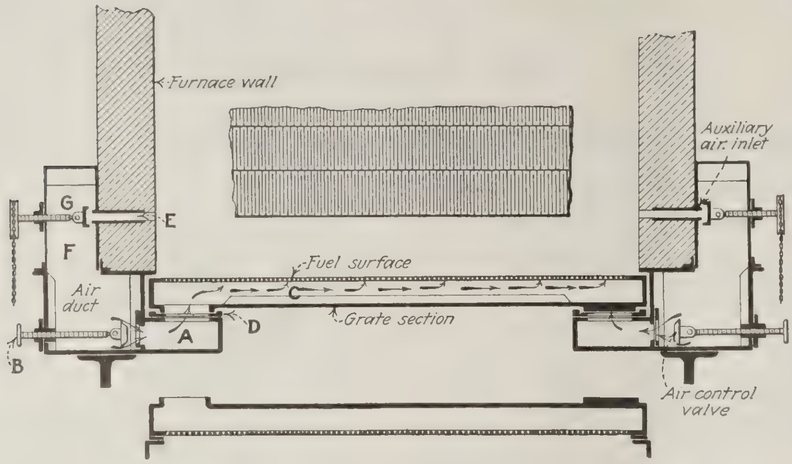


Fig. 2—Detail of Grate Bars and Air Control

Forced draft enters each grate bar separately from the air duct or wind box on the side of the stoker. Pressure of this air is controlled by a series of valves with stems extending outside the air chamber. The exact intensity of draft desired at any point in the fire may thus be obtained.

lator" consists essentially of a series of grate bars extending transversely across the furnace. These are connected together to form a continuous surface, which is inclined toward the boiler front. A series of chambers, *A*, conduct air for combustion to each section of the grate. They in turn being connected to a common air duct placed along the side of the stoker. The quantity of air entering each grate section is controlled by a valve, *B*. A wearing plate, *D*, is interposed between the bottom of the grate sections and the air chamber. The various grate sections are fastened together and pass as a chain over sprockets at both front and rear of the grate, the front sprocket being the driver. The rear sprocket carries a cylindrical sheet-iron drum which prevents ashes from dropping through the grate. Additional air for the combustion of the fuel is supplied through openings in the side of the furnace, *E*, the air passing through being regulated by the valve, *G*, within the air duct on the side. Another source of auxiliary air is that entering through the openings, *H*. This air is supplied to pipes, *J*, by a connection from the top of the wind-box on each side of the stoker. This furnishes air for combustion above the grate.

Fuel is fed to the furnace from a small hopper by means of plungers, *K*, connected to short-stroke cranks driven through a reduction gear from the main shaft, *L*. By feeding the coal to the furnace at this point, it is caused to pass through the hot gases which allows the fine particles to burn in suspension and the larger ones to become ignited before reaching the grate surface proper.

Some of the advantages claimed for this stoker are an ability to sucessfully burn large quantities of coal per unit of grate surface per hour; exceptional capacity, due to the fuel being ignited before reaching the grate and a rapid pick up of rating, due to the large quantities of fuel resting upon the grate.

## Industrial Notes

**St. Louis Power Shovel** Co. has been formed to manufacture and sell the Conway shovel, formerly handled by the Conveying Weigher Co. These shovels, under the direction of Hitchcock and Tinkler, are digging the Moffat Tunnel, near Denver. The shovels were originally developed by the National Lead Co., at its mines in the Flat River lead district. John L. Clarkson is president and Douglas C. Corner, secretary and general manager, of the new company.

**The Electric Service Supplies Co.'s** Chicago office has removed from the Monadnock Building to the Illinois Merchants Bank Building, 230 South Clark St.

**Porter & Ross, Inc.,** of 30 Church Street, New York City, announce the opening of a new branch office in the Coal Exchange Building, Wilkes-Barre, Pa., in charge of Neil Cheshire. This company acts as sales agent for the American Enameled Magnet Wire Co., Eureka Copper Products Corp., Green Equipment Corporation, John C. Dolph Co., Dutchess Insulation Co., Mutual Foundry & Machine Co., Specialty Device Co. and the Kaniksu Cedar Co.

**J. W. Swaren,** Mem. Am. Soc. C. E., has opened an office in the Peoples Life Insurance Building, Washington, D. C., where he will specialize in the preparation of engineering data for submission before federal departments and bureaus. Prior to the war Mr. Swaren had a consulting practice in San Francisco, Cal. He entered the engineer branch of the army in 1917 and served overseas with the Sixth Division, Regular Army. He was discharged from Walter Reed Hospital, Washington, D. C., and became general sales manager and engineer for the Duriron Co., of Dayton, Ohio. Afterward, he was appointed engineer in the Treasury Department at Washington, resigning after two years to enter private practice. For the past two years he has been engaged in the appraisal of several large groups of coal and iron ore mines, including the railways and hydroelectric systems serving the properties. His offices in the Union Trust Building, Cleveland, Ohio, will be maintained. Prior to the war Major Swaren was a frequent contributor to the technical press.

Concrete floors which have become granular are always a source of annoyance and expense. "Rockote," a product manufactured by the **Goheen Corporation** of New Jersey, paint engineers, Newark, N. J., is said to prevent "dusting" and provides a hard, dustproof surface to such floors. It is a scientifically prepared chemical liquid which dissolves the surface of the floor and recrystalizes on drying to a permanent rocklike surface. A descriptive pamphlet on this product and its various uses will be sent by the manufacturer on request.

**The Chicago Fuse Mfg. Co.,** of Chicago, manufacturer of Union and Gem fuses and Union outlet and Gem switch boxes, has moved its Detroit office from the Transportation Building to 429 Wayne Street.

## Trade Literature

**Hardinge Super Thickener and Clarifier.** Hardinge Co., York, Pa. Bulletin No. 30. Pp. 12; 8 x 10½ in.; illustrated. Describes operation, capacity, density of discharge, clarity of overflow and filtrate, etc.

**The Delta-Star Electric Co.,** Chicago, Ill., has issued a net price-list on standardized outdoor substations, to take effect Oct. 15 and remain in force until March 15, 1926.

**Heavy Duty Stokers** (Type K). Marion Machine Foundry & Supply Co., Marion, Ind. Bulletin No. 225. Pp. 12; 9 x 11 in.; illustrated. The semi-mechanical and hand-operated stokers are also described.

**C-H Magnetic Clutches.** The Cutler-Hammer Mfg. Co., Milwaukee, Wis. Publication P-11. Pp. 16; 8½ x 11 in.; illustrated. Describes the uses of these clutches on synchronous motor drives where the starting is severe.

**Freeman-Riff Co.,** Terre Haute, Ind., has issued a folder illustrating and describing the coal handling, weighing and storing equipment at the new power plant of Purdue University, Lafayette, Ind.

**Automatic Switching Equipment for Reclosing Service on 275-Volt D.C. Circuits.** General Electric Co., Schenectady, N. Y. Bulletin GEA-24, superseding Bulletin 47717-B. Pp. 28; 8 x 10½ in.; illustrated.

**High Tension Indoor Universal Unit Type Bus Bar Supports; Adjustable Top and Bottom.** Delta-Star Electric Co., Chicago, Ill. Bulletin No. 31-B, superseding Nos. 31 and 31-A. Pp. 48; 8 x 10½ in.; illustrated, tables.

**Centrifugal Pumps.** De Laval Steam Turbine Co., Trenton, N. J. Catalog B. Pp. 72; 8½ x 11 in.; illustrated. Engineers who have to do with the pumping of water, whether against low or high heads or in small or large quantities, should find much of interest in this publication.

## Publications Received

**A.S.T.M. Standards Adopted in 1925.** American Society for Testing Materials, Philadelphia, Pa. Price, $1.50. Pp. 117; 6x9 in.; tables. Contains 36 revised or newly adopted standards of the society and forms the first supplement to the 1924 issue of the triennial book of standards.

**The Regularization of Employment,** by H. Feldman. Harper & Brothers, New York City. Price, $3.50. Pp. 437; 5½x8 in.; illustrated.

**Architecture and Anthracite.** Anthracite Coal Service, Philadelphia, Pa. Pp. 18; 8½x11 in.; illustrated. Contains information and practical suggestions toward providing architecturally satisfactory and economically sound results in designing and specifying for heating installations, with an article on the appropriate use of anthracite.

COAL AGE

McGRAW-HILL COMPANY, INC.
JAMES H. McGRAW, *President*
E. J. MEHREN, *Vice-President*

Devoted to the Operating, Technical and Business
Problems of the Coal-Mining Industry

R. DAWSON HALL
*Engineering Editor*

Volume 28 NEW YORK, NOVEMBER 26, 1925 Number 22

## Again Mr. Lewis Speaks

THE PRESIDENT of the United Mine Workers in a letter to Mr. Coolidge once more makes threats of a general strike that will involve not only the operators who have seen fit to make private arrangements with their men outside of the Jacksonville agreement but those also, who, operating a long way from the non-union field, have been able, with great difficulty it is true, to pay the union scale.

There are moralists who deplore the situation in the former union fields which signed the Jacksonville agreement and have started their mines with such of their men as are willing to recognize the necessity for a lower wage, but what can these say of Mr. Lewis, who, getting from Illinois, Indiana and Ohio all that the Jacksonville agreement calls for, proposes to call a strike to bring out the men in those states where every detail of the Jacksonville agreement has been complied with, those states, indeed, whose pressure caused the agreement to be made.

No one has criticised Mr. Lewis for trying to call a strike in the Fairmont field. No one could criticize him for calling one anywhere where the break with the union has occurred. But the men in those regions realize that they are getting the only wage economically possible under present conditions and are likely to turn a deaf ear to Mr. Lewis.

A few weeks of high production and higher prices, resulting from the anticipation of a strike may raise prices and give rise to the idea that the old wage rate can be paid, but the moment the assurance is attained that the coal bin will be kept full the old economic situation will reassert itself and the intervening territory between the non-union area of West Virginia and Kentucky and the coal fields of Illinois and Indiana will be back where it was before, and if meantime wages have been raised, the men in that territory will be deprived of work. Let us hope the men will sense this fact and meet it by resisting any attempt of Mr. Lewis to make them take part in a strike that is not to their interest.

## Unionism by Decree

LICENSING IS THE MOST effective form of unionism. It always creates a close corporation, one kept intact by legislative decree. Examine the facts of any licensed body whether of steam engineers, doctors, plumbers or steam fitters, and you will find a union, which may be acknowledged or merely existent without acknowledgment.

In the Pennsylvania anthracite region and in Illinois the miners have their union activities supplemented by the law that licenses them. If that law in Pennsylvania were removed there might be some hope of reopening the anthracite mines. There would, at least, be no legal obstacle such as now exists. The miners will not work nor will they let others work. They may be willing to accept other men's jobs at a lower rate than that at which they will work at their own, but they are able to prevent other men from taking their jobs. Their would-be successors would profit by the exchange, but the law forbids. A license is unionism enforced by legislative decree.

## What Can Coolidge Do?

THE MAN ON THE STREET and the press are patient, but every now and again the cry is heard "Why can't Coolidge do something?" Those who raise it haven't thought out what the President could do. Their minds are by no means clear on the subject, but they believe that a big strike that inconveniences the people can be settled in some way.

When Pinchot brought the previous strike to a termination he burned his fingers badly. He got the operators to make a concession which they had to hand on to the public. After all, if the strike was to be settled, that was about the only way to end it. The mine workers were insistent on getting something, and no appeals to reason or public convenience or patriotism could sway them.

But this time the operators are clear they can hand nothing on to the public, and if wages go up the mines must close. The public is looking to other fuels. So this time the operators are adamant and not to be swayed. They can't be scared, for nothing looks quite so terrifying as a wage increase.

Even Senator Borah's prospective plans for legislative regulation cannot be worse for the industry than to pay a wage that puts the cost of coal above what the public will pay for it. When a man faces a firing squad all the guns are equally menacing, and he is not afraid of any one of them. He bids fair to die any way.

But Coolidge is "doing something." He is being far more active than any of those who reproach him. He is making headway, and they are delaying progress. Those who buy soft coal and coke at his recommendation—especially, alas, those who introduce oil—are helping to effect a settlement. Those who hearten the mine workers with their outcries are the very persons who delay the settlement for which everyone is anxious. When the miners see they cannot stampede the public or the administration but that both are ready to fight it out if it lasts all summer, then there will be a settlement and not before.

The public and the administration were immensely impressed and shocked by what Great Britain did when it ended a strike by the offer of a subsidy. Instinctly everybody said: "Is that where we are tending? Can the unions force us to pay them subsidies? Do they venture to strike against us and hold us up for tribute?" In Great Britain the subsidies aid British mines to compete with foreign mines, but here a subsidy would help anthracite to compete with soft coal, coke, oil and gas. Just conceive of a subsidy to help one industry to hold back the progress of another!

Yet that seems to be the only thing the President and Congress can do unless we are ready to see the fight through. If it is not fought to a standstill now, it must be later. The union is committed to continued steps forward and no backward step. The only way to halt such progress, attained at public expense, is to firmly resolve that this time the matter shall be settled once for all by a finish fight.

What can Coolidge do? Nothing. What should he do? Nothing. The less he does in this matter to bring it to a settlement the sooner it will be settled. "They also serve who only stand and wait."

## The Appalachian Washboard

THE EASTERN Mountain States are corrugated like a washboard, and the mining communities that lie in the bottom of any one corrugation are pretty well segregated from those in every other. Here and there the corrugations are defective. Some river has broken through and made communication from one valley to another possible. But on the whole, connection has been difficult, the more so before the automobile and well-paved roads assisted communication.

Each valley is a good location for a live mining institute and should have one. But institutes are apt to have inbred notions unless there is a little travel. So when meetings are being held in other fields the denizens of the washboard territory should send one or more of their number to represent them and bring back word across the mountains of just what transpired and what was learned about the conditions in neighboring fields.

The valleys of West Virginia in earlier years were inhabited by people to whom the citizens of the nearest county were as unfamiliar as the people of England and Germany. These people had accordingly an extremely narrowed vision. The railroads changed matters a little but directed travel even more markedly to accord with drainage. Now with the construction of roads over the hills, travel is being made possible in all directions, but still it tends to follow the old roads and communities. To overcome all along the Appalachians, in Pennsylvania and West Virginia, the narrowing influences of the environing hills some effort should be made to forge the bonds between institutes and have delegates interchange visits at meetings.

## Light and Safety

SAYS BENJAMIN FRANKLIN, basing his statement perhaps on an old English story: "A little neglect may breed mischief: for want of a nail the shoe was lost, for want of a shoe the horse was lost, for want of a horse the rider was lost, for want of a rider the battle was lost, for want of the battle the kingdom was lost, and all for want of a horseshoe nail."

We may be sure that no one ever made just that diagnosis of the kingdom's misfortunes, and there were, of course, other reasons to which it could rightly be ascribed. That's the rub. We can usually find five or six reasons for any event and sometimes more, and if one of the causes had been absent all the others would have been insufficient to cause the accident. It is so with bad light or bad sight. Accidents are never ascribed to those causes, but it is certain that they are almost as important as carelessness in the causation of injuries.

If in every case of an accident the question were asked "Was bad light a contributing cause?" the answer would often have to be that it was. It is a question that should be asked. R. E. Simpson, an insurance safety man, has been asking it, and as a result of his inquiry he lists 18 per cent of the accidents as due to defective light or 108,000 serious accidents yearly. Commenting on this, one safety man said 50 per cent would not be an exorbitant figure for a case under his observation, and he was not a mining man, but was engaged in an industry where darkness need not be so important a factor as it will ever be in mining.

In many underground accidents imperfect light and vision have a part. To see a danger is to avoid it, and how many hazards there are that become manifest only when the light is strong enough to reveal them. Our mines need more light, and they will receive it.

## Our Domestic Coal Problem

WE MAY BE ABLE some day to find equipment that will make it possible for the average domestic consumer to burn fine high-volatile coal, that cakes, clinkers and smokes, and do it with efficiency and satisfaction but of reaching that ultimate goal we all have some doubts.

Perhaps, it would be better to contemplate the possibility of a central heating plant where a large furnace would supply some forty or fifty houses and would do it with powdered coal or with slack on stoker grates. The growth of the speculative builder, who thinks not in houses but in villages and communities, makes it possible that some day we may see the center, the chateau so to speak, in the village a central heating station and the houses of the citizens grouped about as little chatelets under the shadow of the seigniory. The power house being the largest building with an ornamental chimney could be made the outstanding feature of the community. In Canada central heating plants are quite common. They may be found also in nearly all large cities.

It would be possible to deliver coal to such a plant at minimum cost and to remove ashes from it more easily by far than from the cellars of the citizens. The coal would be properly and completely burned, yet withal fuel of the finest size would be used.

The houses would need no cellars unless that was desired for the storing of trunks, for laundries or for the keeping of vegetables. Here would be a considerable saving that would go far toward paying for the laying of piping and the building of the central heating station.

The saving in the cost of attendance on the furnace would be, of course, considerable. To the coal man, however, the feature that would commend itself would be the demand thus created for run of mine or slack coal.

Further development might make the central heating plant furnish not alone steam for the radiators and hot water but also cold air and ice-cold water. Such a plant might be run co-operatively, every household having a share in the central plant and a voice in its management. It could be separately incorporated and its shares distributed among the purchasers of dwellings or it could be held by them inalienably as running with the fee.

# Putting Efficiency Into Siberian Coal Mining Is Hard Job, American Engineer Finds

## First Efforts in Kuznets Basin Raise Daily Output per Man from One-Tenth of a Ton to More than One Ton and Give Encouragement for Russia's Future

**By Alfred Pearson, Jr.**
Consulting Engineer, Toledo, Ohio

PUTTING SIBERIAN coal mines on a basis of efficiency is a task the like of which no engineer faces in America. Yet it is not impossible. This conclusion is based upon an experience of two years in charge of the northern group of mines in the Kuznets Basin of Siberia. Antiquated equipment, a peculiar mining system, a working force made sluggish by Russian psychology and the natural handicaps which Siberia lays upon industry were not enough to prevent a new management from increasing the daily output per man in the Kuznets mines from one-tenth of a ton to more than one ton, and other improvements augur well for the future of the industry.

The Kuznets coal basin lies south of the city of Tompsk, Siberia. It is wedge shaped, about 80 miles wide, 250 miles long and adjoins the Telbas ore field which is supposed to be the most important iron deposit in Siberia.

While Telbas is destined to be the biggest coal customer of the Kuznets field, sales in the past have been made principally to the Trans-Siberian R.R. for steam coal, to the Ural metal plants for byproduct, gas and steam coals and to a small local domestic and miscellaneous industrial market.

Before the war an important part of the Kuznets output was shipped via the Ob River and its branches, not only to the Ural steel plants, but to the several important cities on the banks of the Tom and Irtish and to the port at the mouth of the Ob which is open to ocean traffic four months of the year. This provided a valuable route for coke shipments as coke is seriously degraded by long distance rail transport.

This field has been commercially worked for about 25 yr. Prior to the revolution it had in operation a dozen mines and numerous prospect holes had been driven. Since, due to the shrinkage of the market, work has been concentrated on four mines.

### KUZNETS COAL WILL DOMINATE

This coal field is so situated, that, as European Russia develops, it will be able to ship its products in competition with the Donetz Basin, the only coal field in European Russia of importance. The "Don" is already extensively worked out, its coals lie under much more difficult mining conditions than the Kuznets coals, and besides it is several times smaller than the Kuznets deposit. So the Kuznets field will some time dominate the Russian coal market. Even today, if the railroads could handle the coal at reasonable rates, certain Kuznets coals could compete with the best Welsh coal at the Baltic ports.

Russian labor is composed of both whites and Mongolians, the latter mostly Tartar. It must be understood that they all are only a generation removed from slavery, that they have been kept by the former government in absolute ignorance and illiteracy, and that the standard of life is about the same as that of the Southern "hill-billy" of the last generation.

This condition is aggravated by the fact that 90 per cent of the population lives at that standard and except in the larger cities the remaining 10 per cent, although living more pretentiously, actually attains only slightly

---

The headpiece shows the No. 8 mine at Kemerovo with the tipple and fire observation tower in the picture. The dilapidated condition in which Mr. Pearson found the property is plainly evident. A great deal of timber is used in these mines but the growth native to the country is poor for the purpose.

This is the first of two articles by Mr. Pearson on Siberian coal mining and his experience with it. The second, treating of mining methods mainly, will appear in a forthcoming issue.

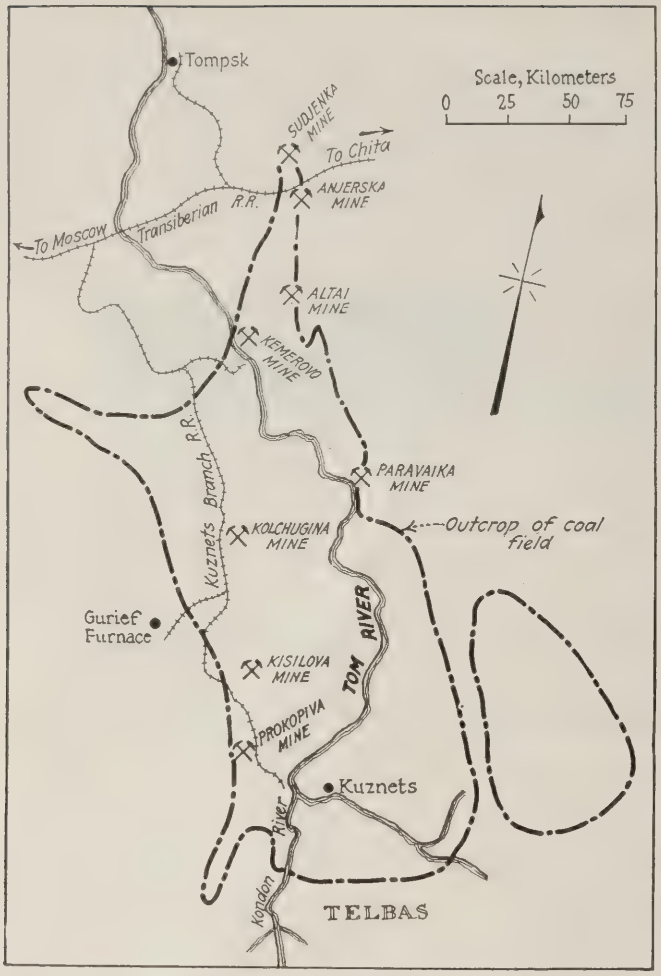

**Fig. 1—Kuznets Coal Field Map**

This shows the proximity of the coal region to the city of Tompsk on the one hand and the great Telbas iron mining field on the other. However, the Russian steel industry needs bolstering to make it a strong coal consumer.

greater comfort, hence these workers cannot possibly visualize any better standard of life than their present one. The worker, consequently, cannot be aroused to earn more, because he can see no use for more than he has.

To combat this indifference of the worker, the wage scales have been consistently set on a piece-work basis, so low as to force the men to put in a full day for a bare existence. It is said that before the war the foremen also used the lash to drive the men. The natural reaction of the worker now is to still further limit his production.

The labor union is a branch of the government. In theory the plants work open-shop, as membership in the union is not compulsory. In practice, however, it is so much to the interest of the men to belong, that well over 90 per cent are members.

Owing to the psychology of the men and the paternalistic industrial customs, the wage system is highly involved, contributing materially to industrial inefficiency, partly through increased overhead and partly because of the reaction of the operating officials who see only the money wage—really a small part of the labor cost.

I will illustrate the wage system, using a face miner as an example. I am obliged to use figures from memory, those marked "est." are items for which only estimates were ever available. The variables are the cash wages and the hospital charge which was a percentage of the payroll; in this case I use a figure which is extremely high for the country as a whole.

Total Wage

| | |
|---|---|
| Money average | $23 |
| House light, coal, water (est.) | 8 |
| Medical attention | 4 |
| Tools, clothing (including overhead) | 5 |
| Total for 120-hr. work month | $40 |

The piece-work system is applied to every class of work. This requires not only extra accounting and the consequent extra time keepers, but also, when applied to the repair shops and miscellaneous outside activities, a staff of estimators to set the rates for the smallest jobs. And this is not to mention the endless bickering which inevitably arises over wages. The custom of furnishing tools and working clothes calls for an extensive warehouse and staff.

One would imagine such a system would provide exhaustive and accurate cost figures; but the reverse is the case as the so-called Italian system of bookkeeping is employed. It deals with the person rather than the task and results in a mass of figures almost worthless for operating purposes although likely to be entirely satisfactory to the accountant.

### Reorganization Followed Depression

In 1922 the coal mines of Russia were in an advanced stage of disintegration, with the entire country howling for coal. After this period the mines were organized into competitive groups. Experts were employed, back wages paid off and large subsidies granted for improvements. The result was that coal mining attained about the most satisfactory status of any Russian industry. The mines are now producing about one-half the prewar output at a price that is cheap compared to that of other commodities. Due to the weakness of the railroads—which are only 20 per cent efficient—as well as to the weakness of industry in general, it has been impossible for the mines to dispose of their product. Until recently the mines worked on reduced schedules, with mountains of mined coal cluttering up the landscape. Financial support was withdrawn and improvement work stopped.

Russia's domestic market is dominated by wood. This condition will begin to change as soon as the market becomes strong enough to permit full operation of the mines, which, because of reduced overhead, will lower the cost of coal to a point where the burning of wood will no longer be advantageous.

It is understood that the government is about to apply to the steel industry the same methods of resuscitation applied to the coal mines. This should in turn affect the mines favorably.

The equipment of the coal mines is so shaky and the plants themselves are so nearly obsolete that they cannot continue long and will be utterly unable to compete with modern mines whenever (which must be soon) new mines begin to enter the fields.

### Equipment Costs Are High

The design of a modern mine in Siberia is a difficult problem. It cannot always be shown clearly that the substitution of machinery for men will result in a reduction of costs. The mines are so far removed from manufacturing centers that the cost of delivery of materials is extremely high. Furthermore great foresight is required to maintain a supply at mines because

**Frozen In**

This illustration shows a typical coal property of the Kuznets Basin. It is the tipple, headframe and bucketway of the South Mine at Kemerovo where Mr. Pearson made his headquarters. The wide range of temperatures in this territory makes ventilation a serious problem. This however, is not the only handicap laid upon coal mining by Siberia.

it is necessary to look ahead years instead of months as there is so much uncertainty about deliveries. This results in excessive warehouse stocks and oversize repair shops.

One must not expect the application of modern methods to show the results they achieve in other lands. Not only is Siberian labor hard to train, but to gear up coal mining to operate at modern speed will require practically an industrial revolution over the whole country and embracing all industries. Trying to travel at American speed in Siberia is like trying to hurry when you are in the middle of a chain gang.

### Reasons for Low Output

The northern group of mines in Kuznets Basin was in typical Russian condition when I assumed charge of the group. The output per man was at its lowest ebb —one-tenth ton per man shift. This was due to several causes. All the workable mines were operating, although any one of them could have produced all the output. This provided an overhead personnel nearly as numerous as the active workers. A serious shortage of equipment did not permit the men working to produce anything like their potential capacity. The morale of men in the technical staffs was "shot." These men were underpaid, poorly accommodated, discouraged by the past, and apprehensive of the future.

The morale of the workers was even worse. Their conception of the results to be expected from the revolution was a total suspension of discipline and the gaining of a livelihood by half the customary labor. In addition, wages were several months in arrears. This encouraged nobody to work.

The plant layout did not commend itself to the eyes of a man accustomed to modern methods and the machinery was little better than junk.

### System Not at Fault

Such a low productivity combined with a strange mining system, very naturally was at first blamed on the system. Later, when some cost accounting made possible a comparison of results, it was discovered that the system was at least as good as any other, the difficulties being in the execution of details.

At the end of two years of the new management the net result was twice as much coal from two openings at one plant as the entire group of mines had been giving at the beginning. This was accomplished at about one-half the cost per ton, and with a man shift output of more than one ton. Concentration of work, prompt payment of wages, reduction of staff and improved accounting all played their parts in the net result.

In the mine work proper three changes were the most revolutionary, one was a reduction of the working face, which, by reducing the number of men being paid from one check, actually doubled the output per man by cutting out the suspicion on the part of each man that the other fellow was loafing at his expense. This was an innovation which received the hearty support of the Russian engineers. They had spent their lives trying to break up the "artel" system, a typical Russian institution in which a large group of men contract a job together. It had been long known that the men did not work well under this plan and were almost impossible to discipline. To produce the change it was necessary to double the narrow work, in itself not good mining practice, but on trial it actually reduced the cost of coal.

### Big Improvements in Haulage

Another change was the substitution of 1½-ton for the old ⅓-ton wagons. This resulted in a big saving in transport costs but necessitated a revolution in trackage. The Russian engineers had been fully aware of the advantage of bigger transport units but lacked the nerve to make the change. They feared discredit because the new system is so far reaching, involving better road beds, heavier rail, and broader gages. Broadening the gage conflicts with shaft layouts. Ordinarily a modern transport system will be possible only in new mines especially laid out for the purpose.

In this case it was possible to lengthen the cars without changing the gage of 22 in. This was not wholly satisfactory but proved better than the old system. The entries had been laid throughout with double tracks of 12-lb. steel. It was necessary to lay heavier rail, but as a double track system was not needed, a single track proved an actual economy.

### Change Time of Shifts

The third change involved the hours of operation. The mines had been working 24 hr. a day. Underground men had worked four 6-hr. shifts; outside men three 8-hr. shifts.

When the change was made, at first the policy was to get out the coal regardless of cost or efficiency. By concentrating all handling of materials and other nonproductive work in one shift quite an improvement was made.

Later a slackening in demand made it possible to cut off one mining shift, by allowing a 2-hr. interval

**Sixty Below but What of It?**

Here we have a couple of engineers setting out on an inspection trip in a typical horse-drawn Siberian sleigh. Temperature ranges are wide in this coal mining field but all you have to do is get used to it—and bundle up in furs.

between shifts. This eliminated some delays that had been suffered while waiting for powder smoke to clear. Also some surface friction was removed because surface and underground workers reported at different hours. Unfortunately for the purpose of measuring the relative advantages of the old and the new systems it was necessary to cut off another shift immediately as the output was not reduced sufficiently. However, there had been shown a big gain in output per man.

Soon after, a fire in part of the mine forced a return to the three shifts; and when it was possible to resume the experiment several other minor improvements so befogged the results that comparison is impossible. One of these improvements was the substitution of electric cap lamps for oil hand safety lamps. To this change the mine foreman attributed a gain of 20 per cent in efficiency.

### Safety Problems in Many Hands

"Safety First," is no by-word in Russian mine practice. The mine law, casually read, is apparently similar to the best of our American laws, but it reflects the Oriental idea of personal retaliation, and is inflexibly drawn. This results in a loss in initiative on the part of operating officials, which in turn, tends to encourage lower production per man.

The manner in which the law is written offers inspectors and operating officials no opportunity to exercise judgment. Enforcement of the rigid specifications of the law is supposed to be in their hands but it actually is not. The state mine inspector, being a mining man presumably will favor his professional brother the operating official; so a local labor inspector also goes over the ground. In addition, the miners' union maintains an expert who covers the same ground and, as the superintendent of the rescue station has little to do, he, too, takes part in the discussions. After one becomes acquainted with these worthies, of course the proper method of procedure for the mine management is to stir up a fight among them and plead inability to choose the best advice.

### Volunteer Rescue Squad

A fully equipped mine rescue station is maintained by the government at each gaseous mine—which, in Russia, means nearly all mines. It is manned by a superintendent, a trainer and three attendants on duty turn about, during the 24 hr. of the day. The crew is made up of volunteers from the miners.

It has been said that our American method of choosing petty mine officials is too informal. In Russia it is too formal. Only men who have been through a regular course of instruction can hold places of responsibility in the mines. Assistant mine foremen take one course, known as a "desetniks" course. Mine foremen are required to take another. These men are known as "mine tekniks." So far as I could learn it took these men as long to finish their course of instruction as it did an engineer to take his degree, yet the more responsible positions were not open to the foremen. Construction work and surveying are done by men specially trained in those branches. I was at a loss to discover the real difference between a "teknik" and an engineer. One observes that the effect of having each job performed only by men who have gone through a certain course, is to make the work seem poured through a mould. It is to be hoped we never will become so formal in this country.

**Siberian Cold Stays Out**

This typical Siberian house in a coal mining town is built 20 x 50 ft. on the ground and is supposed to house four families. But when housing was short in the village, seven families occupied it. Mine officials are allowed one room and a kitchen each for their families. The house is tightly constructed of logs in the Russian manner to resist the cold winds. Most of the heating is done in fireplaces.

# New Conveyors Speed Room-and-Pillar Mining

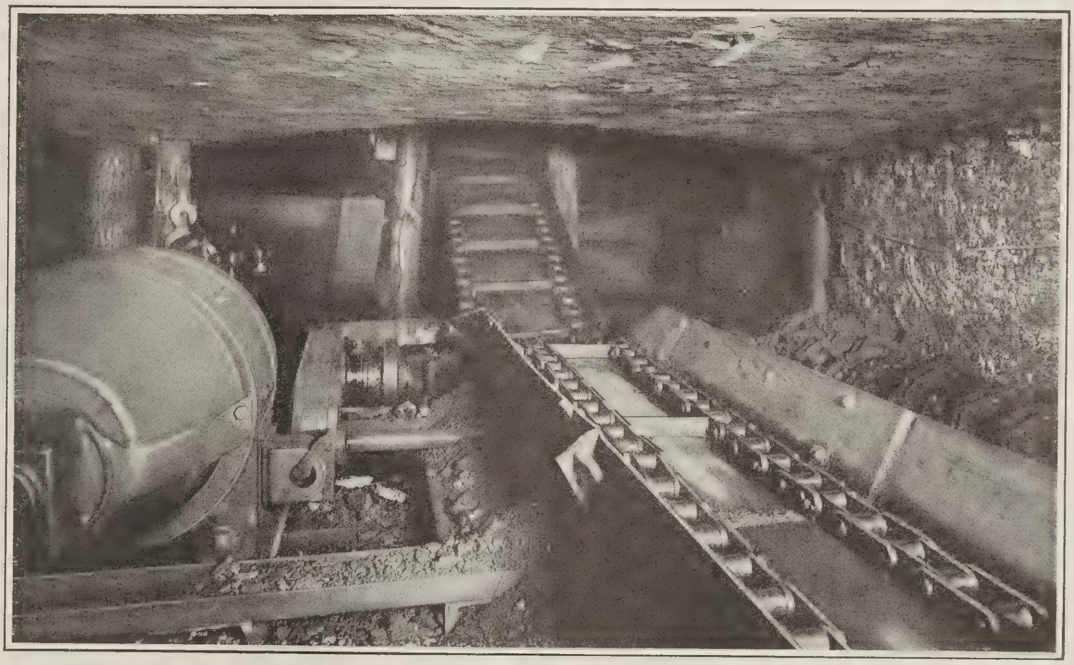
## Self-Contained 12-Ft. Belt Units for Service in Tandem at the Face Discharge into a Sectional Scraper Trough Extended to Any Length Delivering to Cars on the Entry

**By Alphonse F. Brosky**
Assistant Editor, *Coal Age*,
Pittsburgh, Pa.

SWIFT TRANSPORTATION of coal away from the working face is essential to concentrated room-and-pillar mining. In thin coal each fall must be rushed out of the way with especial dispatch. Realizing this and convinced that conveyors have the greatest possibilities for speeding coal from face to cars on nearby entries, Richard A. Suppes, general superintendent of the Knickerbocker Mines at Johnstown, Pa., has designed and put into his own service two new types of conveyors. One is a 12-ft. belt unit for use along the face and the other is a sectional flight conveyor which can be extended to any length to deliver coal to cars.

**Loading-Boom In Service**

In order to avoid crowding and consequent spillage of coal at the junction where the main conveyor discharges onto the loading boom, two features of design are provided. First, the loading-boom chain is wider than that of the main conveyor; second, the speed of the boom is 20 ft. faster per minute than that of the conveyor.



The two conveyors are intended primarily to operate together as one system in the mining of coal from rooms, pillars and entries. In this arrangement the coal is loaded into one or more of the lateral belt units discharging into the main conveyor unit which delivers to cars. The main conveyor unit, with a few slight modifications, is also applicable to face conveying in longwall layouts.

The lateral conveyor, of the belt type, is portable but is not sectional in the sense that its length can be changed by adding or taking away duplicate units. Each one is a self-contained, motor-driven conveyor. The requirements of any room, pillar or entry face can be met by arranging two or more such units in tandem.

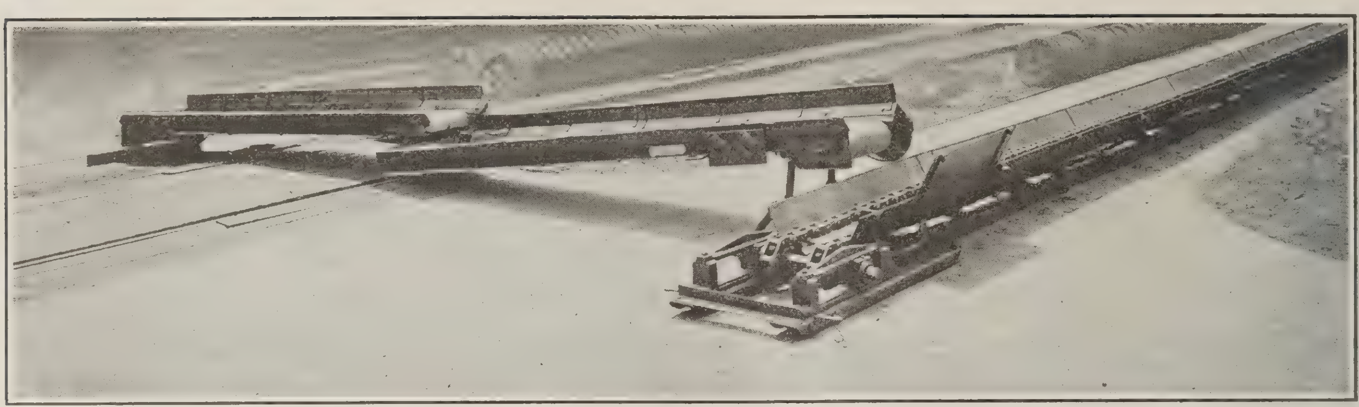
Each of the 12-ft. self-contained lateral conveyor units is provided with a 16-in. composition belt. A plate of steel is bolted to two 3-in. channels forming the main frame of the conveyor. Flared sides of steel rest on beveled wooden stringers and both are bolted to the main frame. Thus is formed a stationary trough, about 3 in. deep, on the floor of which travels the loaded strand of the conveyor belt. Secured to each side of the trough is a rubber flap the edge of which extends over the loaded strand of the belt. This keeps slack from overflowing the belt and crowding under it. The return strand of the belt travels over round rods extending laterally between the channels. Spillage of coal during the shoveling operation is prevented by a demountable extension plate which fits over one trough flare of the conveyor.

The drive pulley and the tail pulley are made lightweight by squirrel-cage construction. Circular disks mounted on the pulley shaft are joined by steel staves which are welded to the disks. The drive pulley is double-conical, tapering slightly from both ends to the center line.

A $\frac{3}{4}$-hp. reversible motor, through sprockets and a chain, drives this conveyor at a speed of 131 ft. per minute. The discharge end of the conveyor is elevated over the main conveyor by an adjustable 4-legged, telescopic pipe support. A take-up on the tail end of the conveyor provides an adjustment to take care of belt stretch. The overall height of the conveyor, at the discharge end, is 27 in.; the maximum shoveling height is about 16 in. and the minimum $8\frac{1}{2}$ in. One unit complete with the drive weighs 570 lb.

The main conveyor is of the scraper type, portable and sectional. In it are a tail section, as many intermediate sections as are required for a given length and a head or drive section, with which is incorporated a loading boom—all propelled by one motor.

The tail section is constructed exactly like the intermediate sections except for the addition of a take-up



**This Photograph Shows One Side of an Arrangement of Face Conveyors**

These short, lateral belt-conveyors which discharge into the main conveyor either singly or in tandem are self-contained. One 10-hp. motor drives as much as 250 ft. of the main conveyor and a loading boom also.

and a tail sprocket. The tail section is mounted on a pair of channel-iron sled runners to facilitate the insertion or removal of intermediate sections. It is provided with a demountable extension plate which prevents spillage of coal at the point where the lateral conveyor discharges into the main conveyor. The weight of this section, without chain, is 363 lb.

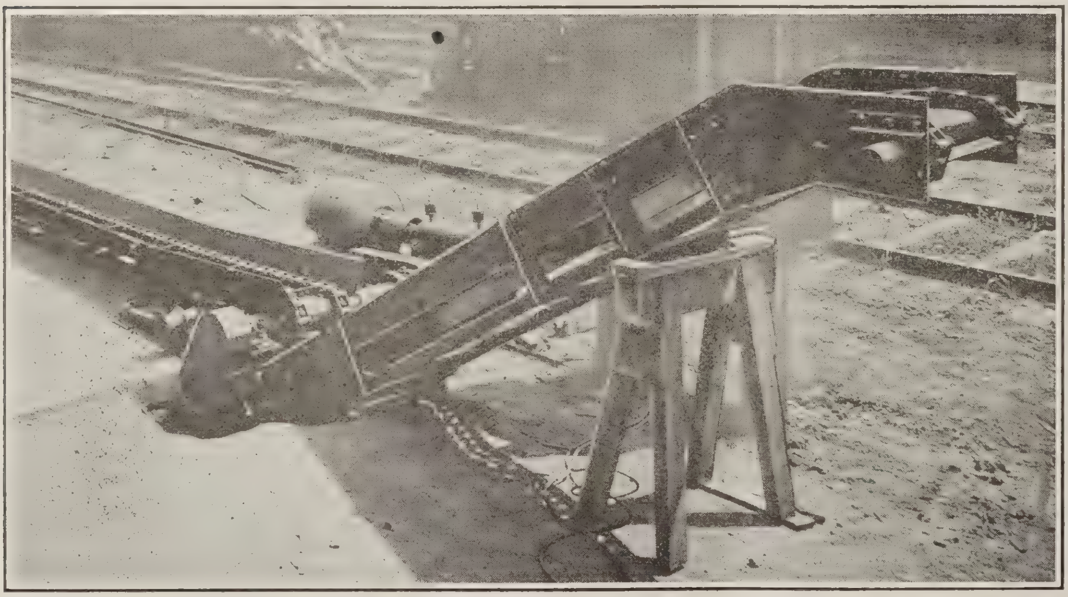
Each intermediate section is 6 ft. long and 13 in. high. The main frame of each section is a pan of ⅛-in. steel plate which is troughed with flared sides. This trough is 20 in. wide at the top, 5⅞ in. deep and 13 in. wide at the bottom. In this trough travels a double drag chain. Flights on 24-in. centers are welded directly to the links of the chain. Sections of chain are fastened together by cotter pins.

On the longitudinal center of each trough and riveted to each flare are two strap steel legs which support the trough. These legs are tied together at the bottom by a ⅝-in. removable round rod. Within the two legs—one at each end of the rod—are two rollers which act as idlers for and serve to support the return strand of the chain. Above the rollers, the inside surface of the legs is rounded, allowing the chain to rub these legs without fouling.

The ends of the flared sides of the conveyor trough are bent to 90-deg. flanges. Two slots are cut in the flanges on one end of a trough, into which fit two U-bolts on the flanges of the mating end of an adjoining trough. A soft-iron wedge inserted in the U-bolts key together two trough sections. The bottom of each trough at both ends is bent under in a half-oval, to provide a rounded joint no matter what the vertical inclination may be between any two adjoining sections. The joint flanges spring enough to allow the conveyor to conform to the profile of the mine floor.

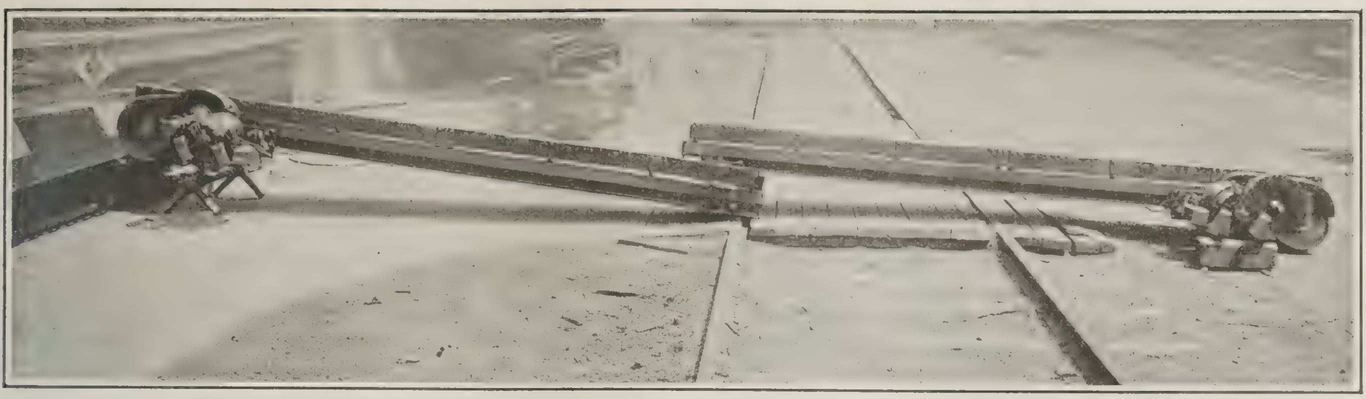
In moving intermediate conveyor sections the trough and chain are handled separately. A trough weighs 80 lb. and a 12-ft. length of chain weighs 196 lb. To shorten the conveyor by 6 ft. the intermediate segment adjoining the tail section is removed. First the take-up is loosened and the intermediate trough section is disconnected from that adjoining it by the removal of the retaining wedge keys. Next, the lateral rod through the legs of that section—which supports the return strand of the chain—is withdrawn, causing the latter to rest on the ground. Then a 12-ft. length of chain is removed from within the trough; the trough is lifted out of the conveyor line; the tail section is shifted forward and joined to the nearest intermediate section; the open ends of the chain are joined, and finally the chain is tightened by means of the take-up. Intermediate sections are added in the same general manner. Either operation can be performed by three men in about 3 minutes.

The head section terminates in a heavy sprocket shaft which, through a worm type speed-reducer from a



**A Side View of Loading Boom**

The main conveyor is driven by a 10-hp. motor through a worm-type speed reducer to a sprocket shaft on the head section. A chain from the main sprocket shaft drives the loading boom.



The Other Side of a Pair of Face Conveyors in Tandem

Each self-contained, lateral conveyor is driven by a $\frac{3}{4}$-hp. motor and weighs 570 lb. complete. A demountable extension plate is added to one flare of the conveyor trough to prevent spillage of coal over the side of the conveyor during the shoveling operation.

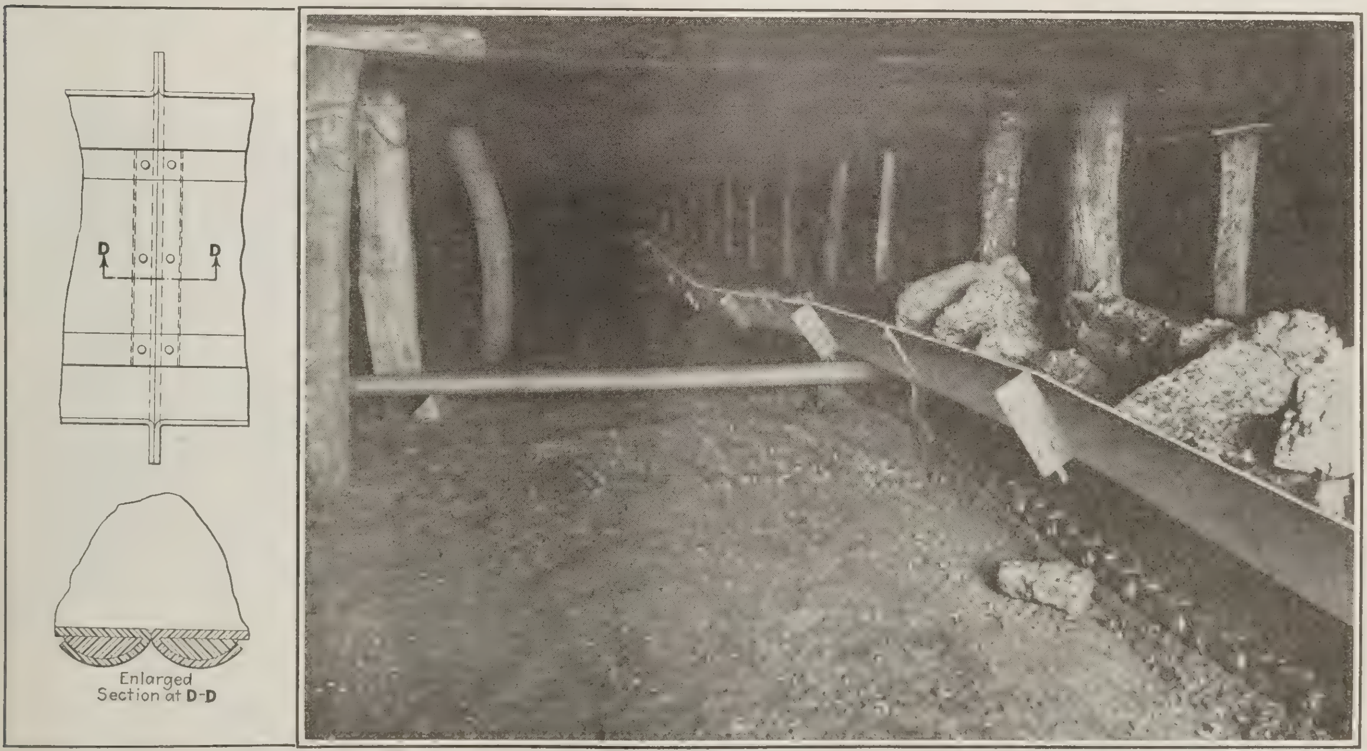
10-hp., reversible motor, drives the main-conveyor chain at a speed of 118 ft. per minute. A flexible coupling is inserted between the motor and the speed-reducer. The sprocket shaft is equipped with a safety coupling, held by four heavy nails which are sheared by an overload or a disarrangement in the equipment, preventing damage to the drive.

On the sprocket shaft also is a clutch which, when engaged, stops the conveyor and drives a capstan located on one side of the conveyor. With the capstan and a rope, sections of conveyor can be hurriedly dragged to safety in case of an impending fall at the face. The weight of the head section, without chain, is 512 lb. and the weight of the drive unit is 975 lb.

The 10-hp. motor, in addition to propelling as much as 250 ft. of main conveyor, drives also the loading boom into which the main conveyor discharges. This is accomplished through the medium of a chain from the sprocket shaft of the main conveyor to a similar shaft on the boom at a speed of 138 ft. per minute. This speed is made 20 ft. per minute faster than that of the main conveyor, to avoid crowding of coal at the junction point.

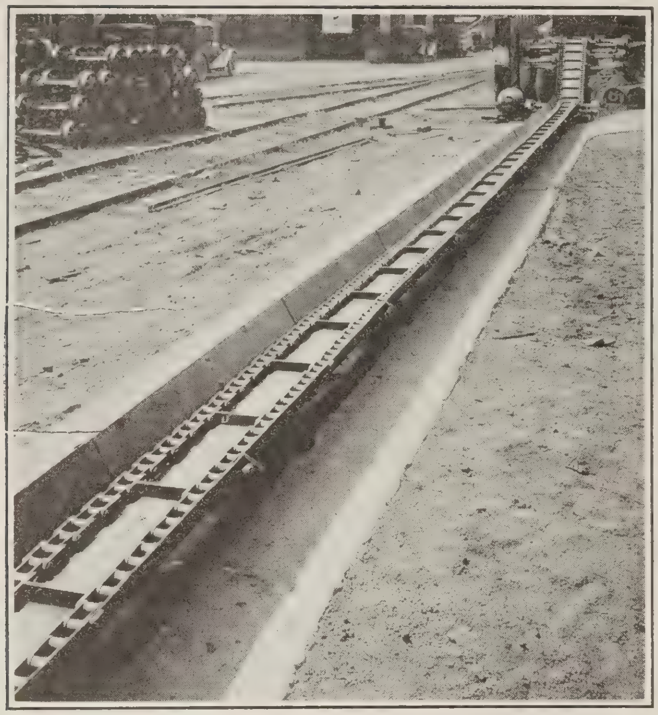
The loaded strand of a 20-in. scraper type roller chain, with flights on 16-in. centers, runs on the floor of a box trough, while the return strand runs on angles which are made a part of the frame. The boom is provided with a take-up which is located on the tail end. The loading boom is 9 ft. long, from sprocket center to sprocket center, and can be set at any angle up to 32 deg. depending on the height of the mine car to be loaded. At its maximum angular elevation the underside clearance is 3 ft., 9 in. as measured from the mine floor (not from the rail), and the maximum height is about 4 ft., 9 in. Bottom clay or top rock, of course, can be removed to provide any desired clearance above and below the boom. The loading boom, complete with chain, weighs 885 lb.

None of the chain requires lubrication. All other bearings are lubricated by a high-pressure feed system.



Main Conveyor Conforms to Any Bottom Because It Is Jointed

In the flanges, by which the trough sections are joined in the manner shown by the drawing is a certain amount of "spring" which allows the vertical line of the conveyor to fit the profile of the mine floor. The clean and fresh appearance of this place indicates speedy recovery. "In and out again in a jiffy" is the motto of the men who operate this mine.



**Trough and Chain of Main Conveyor**

The upper strand of the chain travels in the flared trough and the lower strand idles over rollers on rods which are inserted through the supporting legs. Flights on 2-ft. centers are welded to the links of the chain, which is of the drag type.

The main conveyor is reversible to facilitate the transportation of supplies and equipment to the face, and is controlled either from the loading-boom end or the face end, in the latter case through a no-voltage release.

Twelve hours are required by five men to disassemble the equipment, in a worked-out place, move it to a new place and reassemble it. This equipment can be applied to a 30-in. coal seam. It is suggested that a 5-hp. hoist be provided in conjunction with this equipment to enable one man to load and spot mine cars in trips of 25 cars.

The new conveyor is manufactured by the Lorain Steel Co., Johnstown, Pa. Its application to low-seam coal in two central Pennsylvania mines will be described in a future issue of *Coal Age*.

## What It Costs to Paint Town In Mining Region

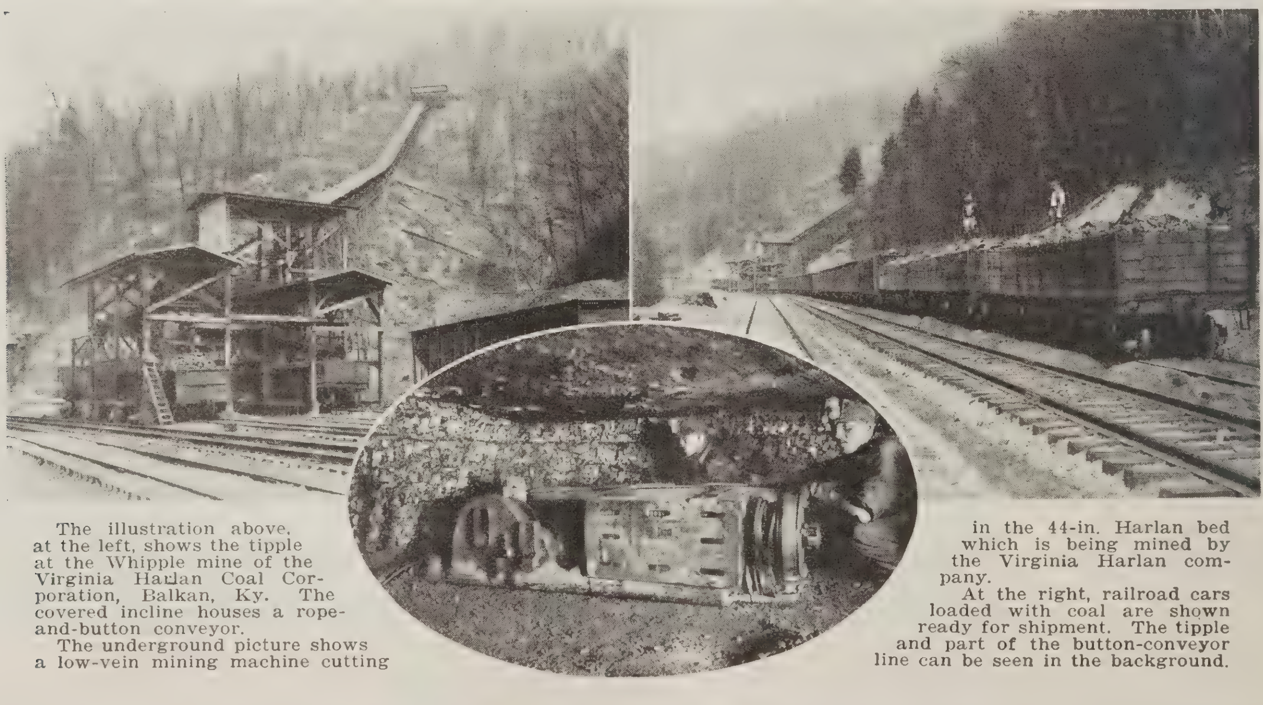
Recently The Union Pacific Coal Co. repainted its houses in the town of Winton, Wyo., a few miles north of Rock Springs, using a spray gun for that purpose. The costs were as in the accompanying table:

**Costs of Repainting 75 Houses**

| | | | |
|---|---|---|---|
| Cost of material | | | $2,058.54 |
| 132 | gal. gasoline | $36.72 | |
| 3 | qt. oil | 3.90 | |
| 22 | lb. paint coloring | 27.25 | |
| 641 | gal. paint | 1,867.13 | |
| 5½ | gal. dryer | 12.45 | |
| 63 | gal. linseed oil | 90.09 | |
| 10 | paint brushes | 13.25 | |
| 4 | ft. screen | 0.56 | |
| Cost of labor for gun | | | 555.90 |
| Cost of trimming | | | 392.86 |
| Total cost | | | $3,007.30 |
| Cost per 100 sq.ft. for material | | | 1.60 |
| Cost per 100 sq.ft. for labor on gun | | | 0.43 |
| Cost per 100 sq.ft. for all labor | | | 0.74 |
| Cost per 100 sq.ft. for labor and material | | | 2.335 |
| Number of feet of surface painted | | | 128,797 |
| Number of houses painted, 75 | | | |
| Number of roofs painted, 65 | | | |

The painting of the shingle roofs, using a bright green, gave the village, which is in the arid region, a cheerful appearance. Long Beach, a high-class residential town on the shores of Long Island, for many years prided itself on every house having a yellow roof, and around the towns of The Union Pacific Coal Co. many roofs have been given a coat of this pleasing color—a suggestion that others might imitate with advantage.

## A Mining Operation in the 44-In. Harlan Bed at Balkan, Ky.



The illustration above, at the left, shows the tipple at the Whipple mine of the Virginia Harlan Coal Corporation, Balkan, Ky. The covered incline houses a rope-and-button conveyor.
The underground picture shows a low-vein mining machine cutting in the 44-in. Harlan bed which is being mined by the Virginia Harlan company.
At the right, railroad cars loaded with coal are shown ready for shipment. The tipple and part of the button-conveyor line can be seen in the background.

# Use of Pulverized Fuel May Boost Coal Production

## Tests Prove That Low-Grade Coal Burns with Good Efficiency and May Create Better Market For Cheap-Mined Product

**By P. Nicholls**
Fuel Engineer, U. S. Bureau of Mines, Pittsburgh, Pa.

HOW WILL THE USE OF COAL in the pulverized form affect the coal producing industry?

Perusal of some of the literature on the use of powdered fuel might create the impression that the most important effect of its adoption so far as the coal industry is concerned will be a decrease in the demand for fuel, occasioned by or resulting from the greater efficiency attained in the production of heat from it. A study of economic laws, however, will relieve all anxiety on this score, since the cheaper production of any finished article invariably increases the demand for it and, consequently, for its raw constituent materials.

Utilization of coal in the powdered form will doubtless react upon the coal industry in the three following ways: (1) A demand will be created for, and it will become possible to sell, low-grade fuels that previously have gone to waste because of their fineness or their high percentage of ash. Thus, anthracite and bituminous fines and high-ash slack will find a market. (2) A demand for lignites and brown coals—some of which have been difficult or even impossible to burn by other methods—will be created. (3) Where coal is to be mined for use in the pulverized form exclusively, it may be possible to cheapen mining costs by employing mechanical methods of the "hogging" type, removing coal uncleaned from the mine. If a consumer bought the entire output of a mine worked on this basis both consumer and operator might benefit.

A full consideration of the first effect suggested would involve numerical tabulation of the amount of coal used in the pulverized form at the present time and the quantities of fine and low-grade fuels now available at the mines. A rough estimate of the first, indicates that from 15,000,000 to 18,000,000 tons of pulverized coal is now being used annually. The second is too complicated to cover in detail and will vary from mine to mine, from bed to bed, and also with the preparation employed and the demand in any particular district. A fuel which at one time may be considered as a waste product, at another may possess an appreciable value. Any classification or quantitative estimate of the amount of such fuels available would, therefore, be difficult to make.

That low-grade fuels may be efficiently burned in the powdered state has been repeatedly demonstrated both in this country and abroad. The records show that coals containing as much as 40 per cent of ash, or even more, have been successfully burned in this manner. The greater part of such data, however, refer to short periods of time and do not prove that the use of the particular fuels tested would have been possible or truly economical for continuous operation.

Many plants, however, have reported continuous operation, on such fuels, the following being a few examples: The Susquehanna Collieries Co., at Lykens, Pa., is using No. 2 Lykens anthracite containing 12 per cent of ash. It reports an efficiency, including superheater, of 80.7 per cent.

The Cahokia power station at East St. Louis, Ill., adopted pulverized coal in order to be able to burn low-grade fuel. It reports using an Illinois coal containing 12 per cent of moisture, dried to 5 per cent, and 16 per cent ash (18 per cent of which is iron), and having a fusing point of 2,000 deg. F., obtaining from 80 to 84 per cent efficiency without economizers.

The Philadelphia Rapid Transit Co., at its Mt. Vernon station, has burned anthracite waste containing 18½ per cent of ash obtaining an efficiency of 62 per cent.

From France come reports of burning low-grade fuels continuously at several plants: At Montceau-les-Mines a coal containing 27 to 28 per cent ash, having a fusing point of 2,120 to 2,220 deg. F. has been burned with efficiencies of 75 per cent or more. At Etablissements Delaunay-Belleville a mixture of coals running up to 42 per cent ash has been burned successfully. At a certain metallurgical plant, anthracite containing 35 per cent ash has been burned with an efficiency of 74 per cent.

In this country some mines are consuming the low-grade fuels they produce to generate the power necessary for their own operation. An excellent example of this kind is furnished by the United States Coal & Coke Co., of Gary, W. Va., which utilizes its bone coal containing approximately 23 per cent of ash.

### Efficient Combustion Proven

A large number of short-time tests might be cited showing that even poorer coals have been burned successfully. It may be considered as proved, therefore, that combustion of low-grade fuel in the pulverized state has been, and can be accomplished with good efficiency.

Efficiency of combustion, however, is not the sole factor to be considered, and time alone will demonstrate whether the overall economy secured will be such as to permit of a large demand being created for low-grade fuels. Even if equal efficiencies were attained, a number of factors increase the operating costs with low-grade pulverized fuels. Among these should be mentioned the freight and handling charges on the ash and moisture content, the extra power required for grinding, the heavier wear on all machinery, the expense of removing and disposing of large amounts of ash, and the more rapid destruction of the refractories. Furthermore, although good efficiencies can be attained from low-grade fuels, the maximum capacities of the boilers are lower than with the better grades, and the possibility of trouble or stoppage will always be greater.

In time, numerical values may be assigned to these various items, so that it will become possible to estimate the relative economic value of available coals.

It might be suggested that if the coal industry is desirous of obtaining an outlet for its low-grade fuels, it must do its share toward determining the treatment to which these materials must be subjected at the mine, in order to afford greatest economic results.

Unquestionably the employment of powdered lignite and brown coal has opened a way to overcome some of the difficulties involved in their utilization. It has improved the outlook for these fuels although reports indicate that much of the work so far done is in the

---

Abstract of a paper delivered before the spring conference on coal at the U. S. Bureau of Mines, Pittsburgh, Pa.

form of tests and trials. A few of the results reported are as follows: At the plant of the Colorado Fuel & Iron Co., at Pueblo, Puritan lignite was powdered in an Erie City pulverizer and burned in a Seymour type of furnace affording 76 to 77 per cent efficiency.

Trials conducted at the St. Paul Light & Gas Co.'s Island station, on Texas lignite, containing 30 per cent moisture and 20 per cent ash on a dry basis, afforded continuously 154 per cent of boiler rating with 78 per cent efficiency without serious operating difficulties. A rating of 260 per cent gave 76 per cent efficiency, but excessive slag made it necessary to shut down after a four-hour run. In spite of this, however, the tests were considered sufficiently conclusive to warrant placing orders for 10,000 hp. of powdered lignite boilers for a plant at Trinidad, Texas.

Many other tests have been conducted upon this fuel, both in this country and in Canada. In Australia, also, brown coal has been tried. All of these have demonstrated that grades of these fuels that have given considerable trouble, or have been impossible to burn continuously by other means can be used when pulverized.

It would appear that the claim that the utilization of fuel in the pulverized state will ultimately be of direct benefit to the coal industry is justified. It may also be alleged that the utilization of powdered fuel has been of direct benefit through the incentive it has created for large-scale experimentation and the pace it has set for other methods. As to how far improvement in these other methods has been due to the competition of pulverized fuel and how far to their own natural growth, no one can determine definitely.

---

# Dinosaurs Leave Footprints In Utah Coal Mines

A PREHISTORIC animal that paleozoologists have termed the "terrible lizard" or "dinosaur" roamed over the peat bogs of Utah in the Cretaceous period, and he left behind him footprints that Utah coal operators still display with pride. They—the prints, not the operators—are of various sizes, some measuring 30x31 in. The one shown in Fig. 1 is from the mine of the Utah Fuel Co. and is 24 in. wide from one extreme to the other.

The lizard walked along on his hind legs and must have been a most terrible creature, but as its actual identification is difficult, we can only surmise how tall it might have been. To W. D. Matthews, of the American Museum of Natural History, it appears to be a deinodont or big-toothed dinosaur of which group the tyrannosaurus, is possibly the most bulky member. That flesh-eating lizard attained a length of 47 ft., and the animal, counterweighted by its huge tail, stood in a posture a little more erect than that of a dog begging. Thus standing he was from 18 to 20 ft. high.

Apparently the monsters tracked along in the mud above the peat bog, and their feet made a depression in the vegetable mass which remained after the feet were withdrawn, but the mud that was pushed into the peat by the foot ultimately formed a cast of sandstone which was later filled with a shaly material. E. T. Ralph, writing to A. C. Watts, of the Utah Fuel Co., says "this impression had the appearance of being in the solid sandstone, but upon cutting around one of these footprints we found that the sandstone in the print is only about 2 in. thick and is overlaid with several inches of black shale between the exposed footprint and the solid sandstone."

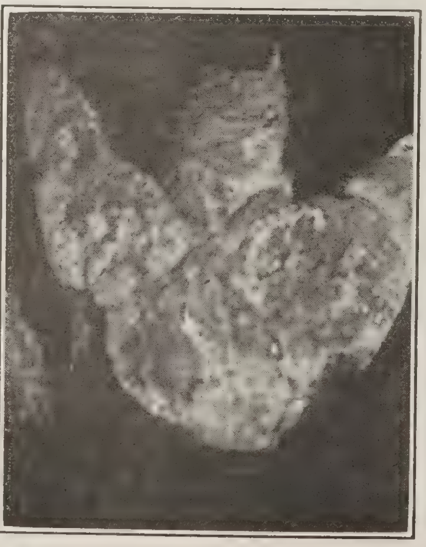


FIG. 1

**Dinosaur Footprint in Mine Roof**

In place of ferns, the mines in Utah frequently have markings indicating the passage of a big lizard over the surface of the peat bog. The coal is surmounted by shale but when the footprints were made the capping must have been of fine sand slime, for that is the material of which the exterior of the footprint is made. The interior of the print is of shale.

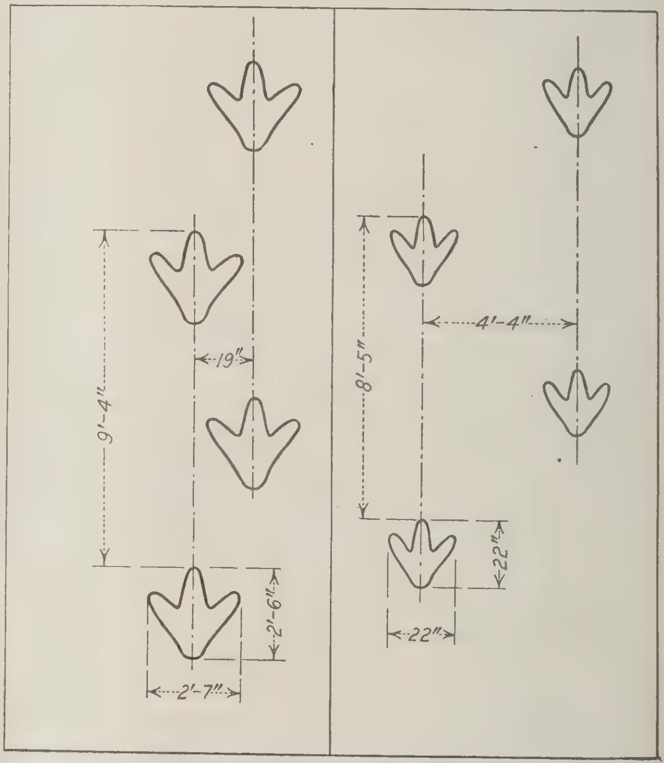

**Fig. 2—Dinosaur Tracks at Castlegate and Ballard**

The smaller measurements are of footprints in the old longwall workings just southeast of Castlegate No. 1 mine opening and the larger show the dimensions of the prints in the old Ballard mine of the American Fuel Co. Note the variation in "wheel gage" so to speak between the larger and smaller animal—19 in. in one case and 4 ft. 4 in. in the other. The Ballard tracks are taken from notes of William Peterson and the other tracks from those of A. C. Watts, chief engineer, Utah Fuel Co.

In the Rolapp mine just north of Castlegate, Utah, footprints are found all along an entry, showing that the tyrannosaurus, or whatever he was, walked in that direction. The outlines have been delineated in crayon and thus is recorded in ancient stone and modern fireboss' chalk the journey which a lizard took perhaps millions of years before the appearance of man. It is said that in many cases the evidence is that there were in those days saurian paths like the cow paths of today; only occasionally did one of these big lizards wander away from the well beaten tribal pathway to make a new roadway of his own over the surface of the plain.

# Improved Ventilation and Safety Practices Pay

By **A. W. Dickinson**
General Superintendent, Union Pacific Coal Co.,
Rock Springs, Wyo.

WITH MINES OPERATING in territory where the coal beds carry a considerable quantity of methane, and with experience in the past which has confirmed the serious nature of the gas and coal dust hazards, The Union Pacific Coal Co. has exercised care in the conduct of mine ventilation for many years. In recent years, added impetus has been given to the handling of the ventilation problem by President Eugene McAuliffe. This attitude has brought about marked changes in the positions taken by all of the staff toward the coursing and conduct of the ventilating current. The feeling at present is, that "good enough" will not do.

Supplementing the work of the safety engineer, the station of ventilation engineer was created in the spring of 1924. The ventilation engineer chosen was a man of engineering training and long experience in the southern Wyoming field, through which he had been in close contact with the underground coal mine conditions of this region. His duties as assigned consist of: (1) Constant inspection of the ventilating systems of all the mines. (2) Study and control of any agency which may result in the ignition of gas and dust. (3) Study and control of fire areas in mine workings.

For the past year a quarterly inspection has been made at each mine by a committee consisting of: 1. A member of the United Mine Workers, chosen and paid by the local union; 2. A member of the United Mine Workers, chosen and paid by the mine superintendent; 3. The safety engineer of The Union Pacific Coal Co. or his representative.

### Miners Approve Program

These quarterly inspections have brought out some points which were constructive and in which remedies have been applied. They also have the value of creating a feeling among the men employed in the mines, that they have a direct interest in the promotion of the safety program, and there is no question but that this manner of inspection has resulted in benefit to the properties. It is clearly indicated that the majority of the men approve of the program. There have been several cases in the past three months where wrong-doers have been reported and punished through the agency of their fellow workmen.

One means taken to promote the safe conduct of the ventilation and all other underground practices, is the employment of one man in each mine known as a safety patrolman. This man reports to the foreman of the mine, and it is his duty to patrol all working faces on working days, seeing to it that men do not work under dangerous conditions, that loose top and loose face coal is properly cared for, that clearances are observed and that the general safety standards prepared by the engineer of standards for the company, together with the safety rules, are carried out. On idle days, the safety patrolman covers the air courses and works on the placement of sprinkling devices, shale dust and the shale dust barriers.

At each of the Union Pacific Coal Co.'s seventeen mines, a recording vacuum gage is placed in the return at the ventilating fan. The charts on these gages are changed every morning before the day shift enters the mine, the mine foreman assuring himeslf of the constant operation of the fan subsequent to quitting time on the previous night. At mines generating methane, daily readings are made of the air volume on each split and weekly reports on air volume and water gage are furnished from each mine.

For the past nine months, all of the seventeen mines have been on closed lights. Shale dusting is being thoroughly carried out in all of the mines, a central plant for the fine grinding having been erected at Rock Springs. Room faces, roadways, empty and loaded cars are wet down. The program also calls for water on the cutter bars of all mining machines.

### More Lump with Less Powder

Permissible powder and electric detonating caps are in use to the exclusion of any other form of explosive. In connection with the use of electric caps, it has been demonstrated that the first delay caps, when used in the firing of a round, result in a saving in powder and an increase in the production of lump coal. Cushioned shooting is also encouraged, and an explosive engineer is employed to follow up the shooting practice, with the purpose of keeping the percentage of lump at a maximum.

Close attention is paid to the construction of overcasts, the ventilation engineer watching the manner of construction and the area allowed. Stoppings are made of concrete; also of double rock wall with dirt pack in the center. In room crosscuts low priced jute brattice is used to stop outside crosscuts and carry air to the actual working face.

In the plastering of stoppings necessary to carry a maximum per cent of air to the working face, a new mixture has been developed since the use of shale dust became general in the mines. Stopping plaster now consists of a mixture of three units of sand, three units of shale dust and ½ unit of portland cement. This mixture does not crack and is considered by everyone to be a real discovery.

### Air Shaft Practice

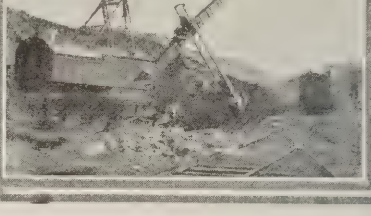
The rule or standard required by the ventilating engineer, is that 75 per cent of the volume of air read at the intake of an entry be conducted through the face crosscut. This requires the very best of stopping practice using projected cement. The new standard in air shaft practice provides that shafts be of circular crosssection, 12 ft. in diameter in the clear. It will be found that it is much easier and less costly to maintain such a shaft.

The improved ventilation and safety practices of the Union Pacific Coal Company have paid and paid generously, not only from the humanitarian standpoint but also in cold, hard dollars and cents. The carrying on of the work has bred a very agreeable relation in the entire body of employees to the great encouragement of everyone concerned.

---

Extracts from a paper presented at the National Safety Council's fourteenth annual congress, Cleveland, Ohio, Oct. 1.

# News Of the Industry



## Lewis Finally Makes Direct Appeal To President, Asking Intervention; Adviser Says Coolidge Will Decline

President Lewis of the United Mine Workers made his definite appeal for government intervention in the soft-coal situation and repeated his more or less veiled threat of a general strike in a letter Nov. 22 to President Coolidge. The letter renewed the miners' contention that the Pittsburgh Coal Co., the Consolidation Coal Co., the Bethlehem Mines Corp. and "coal interests of the Buffalo, Rochester & Pittsburgh R.R." have been violating the Jacksonville agreement and invited the government, as a party that encouraged the making of that agreement, to take a hand toward enforcing it. An authority close to the President at Washington said the President's attitude no doubt will continue to be that there is no law under which the government can proceed against the operators.

Thomas F. Brennan, president of the Buffalo, Rochester & Pittsburgh R.R., denied that his company is interested in any mining companies along its route and therefore is not directly or indirectly interested in the Lewis controversy over violation of the Jacksonville agreement.

Spokesmen for the Anthracite Operators' Conference said the new outburst of Lewis with his old declarations only confirm their contention that Lewis, in bringing about the existing anthracite strike, was trying to use it as a means of getting the government to cure the miners' soft-coal troubles.

In Chicago Stuyvesant Peabody, president of the Peabody Coal Co., said that if Lewis calls a strike affecting the whole Central Competitive Field, in which a good many operators have been living up to the Jacksonville agreement in spite of competitive conditions, he will be doing to them the very thing which he complains certain operators are doing to the union.

The Lewis letter follows:

> In February, 1924, the operators and miners of the Central Competitive bituminous coal fields consummated a wage agreement designed to expire by limitation on March 31, 1927. With this instrument as a base supplemental agreements of similar nature were executed between operators and miners in contiguous and outlying coal districts. The accomplishment met with general public approval, as the agreement gave promise of security and advantage to the public with respect to the factors of continuous supply and price. Agencies of the federal government co-operated in making possible the agreement, the Departments of Justice, Commerce and Labor participating.
>
> The twelfth annual report of the Secretary of Commerce for the fiscal year ended June 30, 1924, at pages 13 and 14, states as follows:
>
> "Through co-operation by the department with the unionized operators and with the leaders of the United Mine Workers a long-term agreement has been entered upon which insures industrial peace in the industry. * * * The industry is now on the road to stabilization. * * * No better example of co-operation to secure the elimination of national waste can be presented. The past year, as compared to the year 1920, shows a saving to the consumer of about $1,000,000,000, which must be reflected in decreasing costs of production in every avenue of industry and commerce."
>
> Without question, the foregoing declaration of accomplishment by the federal government in the public interest was heartily approved by every thoughtful citizen.
>
> Notwithstanding the acknowledged virtue of the before-mentioned contract, I am compelled to authoritatively advise you that substantial coal-producing interests, signatories to the arrangement, have violated and repudiated their written word of honor and in so doing have impaired the integrity of the wage structure throughout the entire bituminous industry. Among the coal companies thus trampling upon and dishonoring their wage agreements with the mine workers are four of the largest coal-producing groups in the nation, viz.: the Pittsburgh Coal Co., the Consolidation Coal Co., the Bethlehem Mines Corporation and the coal interests of the Buffalo, Rochester & Pittsburgh R.R., their several operations being located in northern West Virginia, Ohio and the central and western Pennsylvania coal fields.
>
> To attain their unmoral objective these companies, and certain others of lesser consequence, have utilized coercive and oppressive methods. Their actions have been destructive of all confidence between employer and employee and constitute an unwarranted, indefensible blow at the universally recognized principle of collective bargaining. The savage and dishonest acts of the before-mentioned group has added to the burden of those honest coal operators who desire in every particular to operate in accordance with their wage agreements. The most full information as affecting the representations which I make is available in the departments of Commerce and Labor.
>
> The federal government upon occasion, and from time to time, has intervened in the coal industry. Not alone the operators but the miners have felt the weight of its influence and regulated their policies accordingly. In all respect, the mine workers now inquire whether the federal government desires to intervene to maintain the morality and integrity of the existing agreement in the bituminous coal industry.
>
> If it should occur that the federal government is disposed not to intervene for the protection of a meritorious wage agreement, might the mine workers believe that their own efforts in that direction may be considered as justified?

---

The Great Northern Ry. will extend its oil-burning system eastward from Wolf Point, Mont., to Williston, N. D., which gives oil burners for 1,200 miles from Williston to Seattle. That is about two-thirds of the main line of the road which uses oil instead of coal.

## Massachusetts Utility Gets Winding Gulf Mines In $10,000,000 Deal

The Massachusetts Gas Companies, through their subsidiary, the New England Fuel & Transportation Co., have purchased the E. E. White Coal Co.'s properties at Glen White, W. Va., and the P. M. Snyder properties at Mount Hope, W. Va., as well as the distributing firm of Castner, Curran & Bullitt, which has been agent for the White and Snyder companies. The transaction is said to involve about $10,000,000. The New England companies will take over the three acquired companies about Jan. 1. Negotiations for their purchase have been under way a few months.

The E. E. White Coal Co. operates mines at Glen White and Stotesbury, producing about 1,000,000 tons annually. The mines of this company are two of the largest in the Winding Gulf district and are extremely well equipped.

The P. M. Snyder group of mines include the East Gulf Coal Co., Pemberton Fuel Co., Princewick Coal Co., Longbranch Coal Co., and the Glenco Coal Co. These companies have an aggregate annual output of about 800,000 tons.

Castner, Curran & Bullitt, Inc., which in the beginning of the Pocahontas field sold all of the tonnage produced by the Pocahontas operators, owns extensive docks in New England and a fleet of coal-carrying vessels, which also will be acquired by the new interests.

It is the plan of the new interests to conduct all of the companies purchased under their present names, retaining the corporate identity of each, until a new company can be organized and financed to take over the old corporations.

These interests have an option on another big coal producer in the Winding Gulf field and it is understood that they will entertain propositions from other operators with a view to acquiring additional property in the Beckley seam section of the Winding Gulf district.

E. E. White, head of the coal companies which bear his name, and Lemuel Burrows, head of the firm of Castner, Curran & Bullitt, will retire from active life in the coal business. P. M. Snyder, head of the other companies which are selling out, will go with the new concern as general manager of operations. Otherwise, the personnel of these various organizations will remain the same for the present.

# Hard-Coal Operators Prepared for Finish Fight in War Against Future Strikes; Scout Lewis' Suggestion

The operators more firmly resolved than ever that the anthracite industry must be freed from the menace of recurring strikes; the union officials seeking to win public sympathy while threatening the consumer with a general strike to cut off his supply of bituminous coal—this is the anthracite strike situation as the shutdown in the hard-coal region enters its fourth month.

Despite rumors of growing restiveness in the field, the international leaders of he United Mine Workers still cling to the position taken when John L. Lewis walked out of the conference room at Atlantic City last August and brought the wage negotiations to an abrupt end. The operators, then standing upon the proposition that they could consent to no change in wages which would increase the production cost of coal, now emphasize their counter-demand that the next contract between employers and employees shall contain arbitration provisions that will make future tie-ups impossible.

The latest restatements of the positions of the two sides may be attributed to the action of the operators in again resorting to advertising to make their position plain to the public. Copy placing responsibility for the suspension on the miners appeared early last week in the metropolitan press. A statement from President Lewis of the union, denying that responsibility and declaring that the union had been and was now willing to negotiate in a "give-and-take" spirit followed. To this the Anthracite Operators' Conference, which met at the Railroad Club in this city on Nov. 19, declined to make any formal reply.

### Cites Former Statements

Members of the conference, however, called attention to former statements of the operators' position made by S. D. Warriner at the opening of the wage negotiations last July and at Philadelphia on Oct. 26. In the latter statement Mr. Warriner declared that the operators were prepared to make a finish fight this year to reduce the labor cost per ton in the belief that the public had rebelled against existing prices and to exact a pledge against future strikes.

The conference, it was reported, also scouted the suggestion of Mr. Lewis for a long-term agreement at a fixed wage basis, insisting upon an arbitration clause. As a further clue to their position, a spokesman for the operators asserted that "the strike must go some time longer before a state of mind is reached from which any settlement can come."

Barring government intervention, the opinion is privately expressed that this "state of mind" can not be reached before 1926. Whether government intervention will come is, of course, the big question mark in the present situation. The administration at Washington has consistently held to a policy of noninterference, but there are a number of members of Congress who openly disapprove of that policy. The latest recruits to the ranks of dissenters are Senator Borah, who is reported to be gathering information in a private investigation of his own, and Representative Treadway, of Massachusetts, who has attacked the anthracite industry a number of times.

Pressure also is coming from various private and semi-public bodies. At a meeting in New York last Thursday, the National Council of Traveling Salesmen's Association adopted resolutions calling for an early settlement of the strike and named a special committee to work toward that end. On the other hand, the Washington (D. C.) Chamber of Commerce two days earlier passed a resolution heartily approving "the attitude of President Coolidge in respect to non-intervention by the federal government in the present industrial dispute in the anthracite fields to the end that the differences may be settled within the industry and thus give promise of remaining settled."

In the hard-coal field itself the anthracite operators' negotiating committee is looked to for the next move in the controversy. The New York *Times*' report of what transpired at the New York meeting of the operators last week was given wide publication in the region and a confirmation or denial of the details is expected.

In the meantime the news columns of the region papers are occupied with accounts of the latest move of the Scranton Chamber of Commerce in summoning three representatives of every chamber of commerce in the hard-coal belt to a conference Nov. 24 on the strike in Scranton.

The call for the meeting carried the signatures of Colonel L. A. Watres, president of the Scranton Chamber of Commerce; Eugene Giering, president of the Wilkes-Barre organization, and W. M. Dyatt, president of the Hazleton civic body.

### Mines Seek Financial Help

The District 1 headquarters of the United Mine Workers in Scranton is reported to be receiving many appeals for financial assistance from members of the union in various sections of the field. This is also true of the other districts, Nos. 7 and 9. It is understood that the matter will be taken up with international union officials this week and that a plan of distributing strike benefits will be laid out.

Nothing further is reported from Harrisburg on strike mediation moves by Governor Pinchot. It is understood that the Governor is awaiting the outcome of the latest developments in the situation. The Rev. J. J. Curran, of Wilkes-Barre, also is silent on the aim of his future plans as a mediator.

## More Injunctions Granted In Oklahoma

Temporary injunctions against general picketing by union miners of district 21 and other methods of interference employed by them against open-shop operations were granted to three large coal companies of Oklahoma in federal court at Muskogee early last week, it has been reported. Federal Judge R. L. Williams granted the injunctions.

Officers of district No. 21 of the United Mine Workers and "all other persons affiliated, confederating and arraigning" with them are restrained by the injunctions from "in any manner interfering with, obstructing or stopping the business of the plaintiff companies; from combining and conspiring together to destroy or injure any of said properties, and from inducing, compelling or persuading by means of threats, violence, fraud or deception miners now working in the plaintiffs' mines." A new clause, however, is inserted in the injunction by which the plaintiff companies are restrained from interfering in any way with picketing by three women and one man allowed to go near each mine.

The restraining orders concern actions of the union miners in connection with open-shop mining operations of the Coal Creek Coal Co., of Henryetta; the Wise-Buchanan company, of Kansas City, and the Missouri-Kansas-Texas Ry.'s mine near Coalgate.

## Adopt Plan to End Shortage Of Cars on L. & N.

Agents of the Louisville & Nashville R.R. and the Traffic Committee of the Hazard Coal Operators' Association have worked out a system by which a greater flow of empty cars will be received at the mines in southeastern Kentucky and relieve the shortage which has existed for the last month. Mines that require cars will specify the number needed, how many will be used exclusively on the L. & N. Lines and how many will be used on the connecting lines. In event that cars are loaded at the mines for other than those connecting lines for which they were sought an explanation will have to be made.

The Hazard operators said they would rather be assured of six days' work a week and an even flow of tonnage than to have higher prices with three or four days' work a week.

When the shortage from the nonunion fields first became apparent the Chesapeake & Ohio Ry. leased from railways in the anthracite fields more than one thousand cars to take care of the extra demand. The Louisville & Nashville, however, made the plea that the C. & O. could afford to do this because of its being interwoven with the Van Sweringen system, which would permit cars to stay on the rails of that road. The L. & N., however, pointed out that when its cars reached the Ohio River these were given over to other lines, which, having no interest at stake, cared not when such empties would be returned.

## Scott Turner Sworn In; Lyon and White Become Assistant Directors Dec. 1

Scott Turner, the recently appointed director of the Bureau of Mines, made a flying trip to Washington from Toronto last week to take the oath of office. He was sworn in Nov. 16. He will not take over the duties of the office, however, until Jan. 1. Mr. Turner accepted the position on the understanding that he would be allowed time to conclude private work in which he is engaged.

During his brief stay in Washington Mr. Turner declined to comment on any phases of the bureau's work or on its reorganization. This latter matter, he said, is being looked after by a highly competent committee representative of the industry. He expressed the opinion that the mining industry is particularly fortunate in having Secretary Hoover's help in the effort to solve some of its problems.

Effective Dec. 1 the work of the Bureau of Mines will be divided into two major branches, each to be presided over by an assistant director. One will be known as the technologic branch, with Dr. Dorsey A. Lyon as assistant director in charge. The other will be known as the economics branch, with C. P. White, the assistant director, in charge.

Under the technologic branch will be grouped the following divisions: Mining experiment station, safety service, miners' health and sanitation, mechanical engineering, metallurgy and mineral technology, petroleum engineering, explosives engineering and mining research. The Mine Safety Board and the experimental mine are grouped in this branch.

The economic branch is new and will deal with the statistical, industrial and commercial phases of coal, metals, other minerals and helium. The branch is subdivided into divisions as follows: Coal, petroleum, helium production, minerals and metals, and statistics. The Government Fuel Yard will be administered by the coal division. The minerals and metals division is divided into sections as follows: Iron ores, copper, lead and zinc, precious and rare metals; clays and other ceramic material, non-metallics.

### Transfers Commodity Division

Mr. White, the new assistant director, has been the chief of the commodity division in the Bureau of Foreign and Domestic Commerce devoted to coal. The work of this division has been transferred to the Bureau of Mines and its work will continue under the immediate direction of Mr. White.

Some thought has been given to a plan of retaining in the Bureau of Foreign and Domestic Commerce those activities pertaining to foreign trade of its Coal and Minerals divisions which now are to go to the Bureau of Mines. It now has been decided, however, that even that part of the work can be handled best by the division itself.

It is recognized that the bureau must be prepared to handle additional coal statistics. The hope is that a plan can be worked out whereby the figures can be submitted on a voluntary basis, or it may be that Congress will require the submission of basic statistics.

One of the important questions which will be discussed by the advisory committee at its next meeting, probably during the first week of December, will be the matter of safety work. This is one of the fundamental activities of the Bureau of Mines and some changes probably will be made to give added emphasis to its importance.

National Photo.

**New Director of Bureau of Mines Inducted Into Office**

Scott Turner, of Lansing, Mich., being sworn in as Director of the Bureau of Mines. Mr. Turner was appointed by Secretary Hoover to succeed H. Foster Bain, who recently resigned. E. W. Libbey (on the left), chief clerk of the department, is administering the oath. Secretary Hoover is standing on the right and C. P. White, Chief of the Coal Division, is looking over his shoulder.

---

## Indorse Coal Sales Reports

Statistical programs for reporting coal sales and shipments were discussed at a get-together dinner of the members of the Huntington Coal Exchange and guests from Williamson and Charleston, held Oct. 23 at the Prichard Hotel, Huntington, W. Va. The delegation from Williamson explained the past sales report of the Bureau of Statistics of the Williamson Operators' Association.

In this system, which was first put into effect May 30, 1925 each reporting company mails to the chief statistician of the association a carbon copy of the acknowledgement of each order. At the end of the week the bureau sends out a report of all sales, showing amount, price and general destination. There is nothing in the report to indicate the identity of the shipper. At the start, only ten companies reported to the bureau, but at present twenty-three companies, representing 64 per cent of the tonnage of the Williamson field, are participating.

The scheme used by the Williamson operators is almost identical with that of the Hardwood Manufacturers' Association, which was adjudged by the U. S. Supreme Court as being in conformity with the Sherman anti-trust law. The National Coal Association has put its stamp of approval on the Williamson report and advocates that each local association adopt a similar plan.

At the Huntington meeting Geo. Bauswine, Jr., secretary of the Williamson Operators' Association, and Wm. N. Cummins, chairman of the statistical committee and manager of the Red Jacket Consolidated Coal Co., explained the details of the plan. Further enthusiastic comments were made by T. H. Huddy, manager Bailey Fuel Co.; Thos. DeVenney, manager, Portsmouth By-Products Coal Co., president of the Williamson association, and Geo. Patterson, manager, Sycamore Coal Co.

F. W. Schoew, president of the Huntington Coal Exchange, stated that most of the members of that body are submitting a weekly report of past sales, but that these reports are submitted in card form without mention of the consignee, instead of by carbon copy of acknowledgements of orders.

L. B. Ramsey, of the Logan Fuel Co. and president of the Charleston Coal Exchange, indicated his full belief in the benefits of a report such as published by the Williamson association and expressed the opinion that the Charleston exchange probably will adopt the same plan.

---

Belgian coal output in September was 1,914,280 tons, as against 1,844,860 tons in August, 1,945,732 tons monthly average in 1924 and 1,903,460 tons monthly average in 1913; Coke output, 303,280 tons in September, compared with 308,970 tons in August, 346,650 tons monthly average in 1924 and 293,580 tons monthly average in 1913; Patent Fuels; 206,610 tons in September, as again 200,330 tons in August, 167,693 tons monthly average in 1924 and 217,220 tons monthly average in 1913.

# Anthracite Strike Must Be Settled on Basis Insuring Unbroken Supply Is Sentiment in National Capital

**By Paul Wooton**
Washington Correspondent of *Coal Age*

Observers in Washington are convinced that in the public's resort to the use of anthracite substitutes the country is experiencing the most extraordinary economic development since the buyers' strike of 1921. The movement has spread from New England throughout the whole anthracite-consuming territory. Its ominous possibilities to the industry are thought to be responsible for the signs of weakening which are coming from the camp of the United Mine Workers. Apparently the users of anthracite have come to the conclusion that they must get along this winter without that fuel if they do not want this trouble to recur every two years. The attitude of consumers is in decided contrast to that on previous occasions when the public expended its energy in yelling to the federal government for help.

Despite the fact that the swing to substitutes is assuming the proportions of a boycott there is strong conviction that the anthracite operators should refuse to open their mines until the United Mine Workers agree to some plan that will insure the public a continuous supply of the product. They are in a better position than they ever will be again, it is believed, to insist on the creation of some machinery that will guarantee continuity of supply. They will have strong public support in such a stand, with the chances all favoring ultimate success if they are willing to fight out the issue at this time.

The country gradually is learning that this principle of continuous production is of greater importance than are the more talked-of issues. The new determination of the people to get along and allow the parties to the strike to fight it out, rather than force a political settlement which would mean a truce only, is illustrated in Washington. The leading newspaper is carrying as a daily feature detailed instructions as to the burning of substitutes. It is co-operating with the retail coal dealers in the establishment of numerous demonstration stations throughout the city. Builders are allowing the use of new houses for fuel-burning demonstrations. Thousands of persons are being taught how to fire with bituminous coal.

It is evident that the people are willing to put up with smoke, dirt and inconvenience to be free from the uncertainties that come from frequent interruption of production. This uncertainty has more weight than has price. Washingtonians have paid whatever has been asked for anthracite with little grumbling. They are embracing substitutes because there is less danger of stoppage. They have the impression that both operators and men are guilty of incompetence in the conduct of their affairs when they allow such a situation to occur, but they are not much interested in trying to understand the cause of the dispute or in establishing who is to blame. Their temper is such that if they are kept from discarding anthracite permanently there will have to be some assurance that production will be interrupted less frequently.

It is believed that this feeling is so strong throughout the anthracite-using territory that consumers will not be satisfied with any settlement that does not provide guarantees against stoppage. Seven years of railroad operation without interruption of transportation has given the public confidence in the machinery which was set up to insure continuous service. There are those who think similar results could be obtained in the coal industry were ninety days' notice required of any desire to amend the wage agreement, were the contract to provide that production continue during negotiations and were provision made for arbitration if negotiations fail.

From the opening of the present controversy the anthracite operators have announced their willingness to arbitrate all of the questions under dispute. But the public's attitude makes it clear that arbitration is the big issue in this strike. What heretofore has been simply a statement of attitude on the part of the operators now well may be put forward as one of their demands, some reresentatives of the public think.

---

## Nova Scotia Wages Too Low, Says Barrett

Silby Barrett, former provisional president of District No. 26, United Mine Workers, appearing as the principal witness on behalf of the miners at Sydney, C. B., at the Nov. 17 session of the Royal Commission investigating the Nova Scotia coal industry, stated that unrest among the miners was due to the low wages paid, more especially to the datal men. He said $3.35 was too low a rate for common underground labor, if a man hoped to maintain himself and family, and also too low in relation to the wages paid other workers. He believed contract men would be content to have datal men alone get the increase if they were satisfied the industry could not pay more. They would not stand for reduction in their own wages, even though datal men got increases, because even the contract men were not paid enough to live on. On the whole, he believed the contract men would agree to an adjustment.

Mr. Barrett testified that there was unfair distribution of work to some of the British Empire Steel Co.'s collieries, and said the company should distribute its orders over the whole field in order that all mines should share in the work.

---

## *Complete Plans for Boston Coal Service Bureau*

Preliminary organization plans for the establishment of New England coal service bureaus to teach householders how to burn New River and Pocahontas coals have been completed. The Smokeless Coal Operators' Association of West Virginia has opened its first service bureau office in the Chamber of Commerce Building in Boston. D. B. Goode has been made executive secretary and Henry C. Eaton chief combustion engineer. Mr. Eaton is engaging a staff of demonstrators which will be enlarged as occasion requires.

The association, says R. H. Gross, chairman of the executive committee in charge of this feature of the work, is planning to open stations in Worcester, Springfield, Hartford, New Haven and Providence "in order to more effectively and promptly demonstrate to the householder of New England the value of Pocahontas and New River coals." The campaign launched was approved by the association at a meeting held at Boston on Nov. 6.

---

## California Dealers Enjoined Against Unfair Methods

The Federal Trade Commission has issued a cease and desist order directed to the California Retail Fuel Dealers' Association, of Oakland, Calif., and others, in which the respondents are required to discontinue certain business practices found by the Commission to be unfair methods of competition. The Commission found that the respondents combined among themselves and co-operated together and with others to prevent certain co-operative associations from obtaining adequate or sufficient supplies of coal for their business from producers in Utah, Wyoming and elsewhere.

---

## Penn State Loses Engineering Extension Director

Prof. N. C. Miller has resigned as head of the Pennsylvania State College engineering extension department to become director of extension at Rutgers University, New Brunswick, N. J.

While at Penn State Mr. Miller organized extension night schools in Wilkes-Barre, Scranton and Pittsburgh, where most of the courses are devoted to subjects pertaining to engineering work in the coal mines.

Professor Miller also developed a home study plan combining correspondence instruction with local supervision of students. This immensely increased the popularity and general usefulness of the elementary subjects already offered by the department to mining men. The later addition of college-grade subjects still further broadened the range of educational activities in this direction.

## Open-Shop Operations Spread in Union Hotbed Of Upper West Virginia

Another hotbed of the United Mine Workers in Northern West Virginia was invaded Nov. 17, when mines Nos. 88, 89 and 90 of the Consolidation Coal Co., at Wyatt, Harrison County, resumed operation. A force of men was put to work cleaning up the three mines, which dump coal over the same tipple. For years Wyatt has been one of the principal strongholds of the United Mine Workers.

Officials of the Consolidation Coal Co. reported last week that satisfactory progress was being made in the operation of mine No. 63, at Monongah, and O'Donnell mine, No. 57, in Fairmont, the only mine that the company has on the Monongahela Ry.

A new scare was thrown into the operators of northern West Virginia, when producers in the Logan and Kanawha fields tapped by the Chesapeake & Ohio Ry. began incursions into the trade territory of northern West Virginia. The C. & O. operators ask the Interstate Commerce Commission for an all-rail rate over the C. & O. via Charleston, Rencenverte and Durbin and thence over the Western Maryland by way of Elkins and Cumberland. Another tariff asked is to Charleston on the C. & O. and thence over the B. & O. by way of Gassaway. Buckhannon and Grafton and thence over the Allegheny Mountains east of Grafton to points in the East and New England.

If the rate is granted, which probably would carry a differential of $1.10 over the Fairmont rate, it will open up to the C. & O. operators the industrial sections and centers of population tapped by the Philadelphia & Reading through the Shippensburg and Rutherford (Pa.) gateways, and permit coal to move to Hershey, Lebanon, Harrisburg, Lancaster, Reading, Allentown and other cities in northern and northeastern Pennsylvania. Retail coal yards along the Western Maryland have asked for smokeless coal and if this rate is granted it will open up the markets of Hagerstown, Md.; Chambersburg, Gettysburg, York, Pa.; Baltimore and other commercial and industrial sections to the C. & O. operators.

### Labor Shortage in Strike Zone

In a statement issued recently, Bittner said that for the first time since the strike started, April 1, there was a labor shortage in the northern West Virginia fields. "Many men who have been working in the non-union mines of northern West Virginia," said he, "are now leaving and going to other fields, principally the Connellsville coke region."

In the first three days of last week 5,002 cars of coal were produced at non-union mines compared to 5,325 cars in the corresponding period of the previous week. The drop in open-shop tonnage is believed to be due to the recent heavy pay day. Union mines in the first half of last week produced 883 cars, compared to 781 cars in the first three days of the previous week.

## *1,000 More Frick Ovens In; Labor Trouble Appears*

Labor troubles at the mines of the Hillman Coal & Coke Co. and the W. J. Rainey Co. in the Connellsville (Pa.) field had the effect of curtailing shipments last week, although not to any great extent, it is asserted. It is known, however, that one or two consumers of coke had to buy current supplies in the open market because of the interrupted flow. The H. C. Frick Coke Co. started 1,000 additional ovens in the Connellsville field during the week and it is feared that this interest will draw so much of the available man power in the coke field that the independents might be forced to take cognizance of the men's demand that they pay the Frick wage scale, which is $7.50, compared to their $5.

The exact number of men that are out on spasmodic strikes in the coke field is unknown, but estimates place the number from 500 to 1,500.

---

Louis Fodor, of Logan, entered a plea of guilty of using the mails to defraud in the federal court at Elkins, Nov. 18, and was sentenced to serve four months in jail in Ohio County. He had been in jail in Fairmont for some time. Fodor, it was alleged, received $500 from the New England Fuel & Transportation Co., which operates mines at Grant Town and Everettsville, for the purpose of furnishing miners, which the company claims he failed to do, or to return the cash.

### Hearings Are Postponed

Hearings of conspiracy charges against Ettor Del Guzzo and James Feeley, international representatives of the United Mine Workers, and six union miners were postponed until the next session of the Taylor County Criminal Court in April, according to information received from Grafton Nov. 20. The bail was reduced from $3,000 to $1,000. The state asked for the continuance.

The United Mine Workers announced Nov. 20 that they are now engaged in erecting barracks at Ida May, Carolina, Baxter, Watson, Gaston, Montana, Hutchinson and the West Fairmont Shaft, places where plants of the Consolidation Coal Co. are located.

Van A. Bittner, chief international representative of the union in northern West Virginia, on Nov. 20 sent the following telegram to James J. Davis, Secretary of Labor:

"The Consolidation Coal Co., which abrogated its wage agreement with the United Mine Workers, is evicting hundreds of miners and their families who have been locked out since April 1. This should demonstrate to the American government that the flimsy excuses made by Clarence W. Watson, president of the Consolidation Coal Co., that the company was enforcing the 1917 wage scale by an agreement with the miners are not founded upon truth and are without foundation in fact."

## Many Oppose Further Northeast Rate Cuts; I. C. C. May Decide Soon

Opposition to an extension of the Interstate Commerce Commission's order establishing lower through-rail rates on soft coal from West Virginia fields to New England and adjacent states was voiced before Commissioner Campbell, in Washington, Nov. 19 and 20, at the concluding sessions of hearings on this subject, which were begun in New York City. A rather early decision is expected from the Commission and it would not be surprising to see the order extended, to some extent, perhaps as a temporary measure. The smokeless field of West Virginia already has lower rates on lump and egg to the Northeast. An extension was urged to include mine-run and to open up routes from other fields as well.

The opposition was expressed by the carriers, led by the Baltimore & Ohio and the Pennsylvania railroads, by representatives of the bituminous operators of the Pittsburgh, central Pennsylvania and Somerset fields, and by Attorney General Woodruff and Chairman Ainey, of the Public Service Commission, officially representing the State of Pennsylvania.

The main point of opposition was that there is no necessity for an extension of the order, as there is ample soft coal in Pennsylvania to fill the requirements of New England and sister states at a lower freight rate. To transport coal from the Southern fields across the Pennsylvania fields would be a waste of car capacity and other transportation facilities, it was argued. There are 741 idle soft-coal mines on the lines of the Pennsylvania R.R., the spokesman for that carrier testified, of which more than half are in the low-volatile field of Pennsylvania. The same spokesman said there are 1,200 cars of coke at Perth Amboy awaiting consignment for lack of demand.

In the final hours of the hearing spokesmen for the carriers, while not relenting in opposition to any extension of the order, asked that if an extension be declared, it be made temporary, with a definite date of expiration without prejudice to future proceedings toward a permanent order.

---

## Gets Five West Virginia Mines

Basil H. Lucas, of Shinnston, W. Va., representing Eastern capitalists known as the Acme Coal Co., has taken over the mining interests of J. Edgar Long, of Clarksburg, W. Va., according to reports. These include the Burke mine of the J. E. Long Coal Co., Kester mine of the Long Fuel Co., South mine of the Interstate Fuel Co., Nancy mine of the Castle Fall Coal Co. and Rex mine of the Hamilton Industrial Corporation. Newspaper reports indicate that Mr. Long was East recently working out details. It is reported that he will continue his connection with the J. E. Long Coal Co., a wholesale firm, with M. C. Raikes in charge. It is reported that he will devote more time to the interests of the Union Explosives Co., of which he is president and treasurer.

# President Coolidge Warns Against Extravagance and Inefficiency of Government Activity in Business

National and world service opportunities open to American business were eloquently discussed by President Calvin Coolidge in an address to the Chamber of Commerce of the State of New York at the Waldorf-Astoria Hotel, New York City, Nov. 19. Something far above "a sordid desire for gain" was the foundation of true business, the President told his audience. How business may best measure up to its opportunities and how the national government can co-operate in advancing those aims were themes which were emphasized again and again during the course of the speaker's remarks.

A better understanding of the problems of government by business and of business by government is much to be desired, said the President. Even more important, however, is "the largest possible independence between government and business. Each ought to be sovereign in its own sphere. When government enters the field of business with its great resources, it has a tendency to extravagance and inefficiency, but, having the power to crush all competitors, likewise closes the door of opportunity and results in monopoly." Business attempting to run government leads to the setting up of special privileges.

"It is always a problem in a republic," continued the speaker, "to maintain on the one side that efficiency which comes only from trained and skillful management without running into fossilization and autocracy, and to maintain on the other hand that equality of opportunity which is the result of political and economic liberty without running into dissolution and anarchy." The economic and social status of the citizens of the United States shows that this country is advancing along the right road in its efforts to maintain this balance and to preserve both economic and political freedom.

### Defines "True Business"

"True business represents the mutual organized effort in society to minister to the economic requirements of civilization. It is an effort by which men provide for the material needs of each other. While it is not an end in itself, it is the important means for the attainment of a supreme end. It rests squarely on the law of service. It has for its main reliance truth and faith and justice. In its larger sense it is one of the greatest contributing forces to the moral and spiritual advancement of the race."

Because business plays such a big rôle, the promotion of its success has been a constant aim of the federal government. The effort has been to reduce interference to the minimum. Except for safety, health and taxation, the law has entered little into the work of production. Legislation has been more exacting in the field of distribution because "the whole policy of the government in its system of opposition to monopoly and its public regulation of transportation and trade has been animated by a desire to have business remain business.

"It is my belief that the whole material development of our country has been enormously stimulated by reason of the general insistence upon the part of the public authorities that economic effort ought not to partake of privilege and that business should be unhampered and free. This could never have been done under a system of freight-rate discriminations or monopolistic trade associations. These might have enriched a few for a limited period, but they never would have enriched the country, while on the firmer foundation of justice we have achieved even more ample individual fortunes and a perfectly unprecedented era of general prosperity."

The more favorable public attitude toward large production units leaves the government free to advance from the problems of reform and repression to those of economy and construction. Through the Department of Commerce great strides have been made in the elimination of waste. The government has aided in the post-war regeneration by a program of economy in its own operations. "By an enormous reduction in taxation, it has released great amounts of capital for use in productive effort." As a result of this devotion to efficiency and economy, wages have been advancing and the commodity index declining.

### Not a Selfish Prosperity

American prosperity, maintained the President, has not been a selfish prosperity. Out of surplus savings the United States has advanced vast sums for Old World, South America and Far East refinancing. Such loans, "if rightly directed, ought to be of benefit to both lender and borrower. If used to establish industry and support commerce abroad, through adding to the wealth and productive capacity of these countries, they create their own security and increase consuming power to the probable advantage of our trade. But when used in ways that are not productive, like the maintenance of great military establishments or to meet municipal expenditures which either should be eliminated by government economy or supplied by taxation, they do not appear to serve a useful purpose and ought to be discouraged."

The efforts and accomplishments of the United States to assist in European rehabilitation, "whether they be appreciated at home or received with gratitude abroad, which have been brought about by the business interests of our country, constitute an enormous world service. Others have made plans and adopted agreements for future action which hold a rank of great importance. But when we come to the consideration of what has been done, when we turn aside from what has been promised to examine what has been performed, no positive and constructive accomplishment of the past five years compares with the support which America has contributed to the financial stability of the world. It clearly marks a new epoch."

## *New York Central Orders 3,000 Gondolas*

Orders for 4,500 freight cars to cost approximately $9,000,000 have been placed by the New York Central Railroad, one of the largest equipment orders placed this year. The Pullman Company will supply 1,000 gondolas of this order, the General American Car Co. 1,000, the Standard Tank Car Co. 500 and an additional 500 has been ordered from the Illinois Car & Manufacturing Co. An order for 1,500 55-ton new steel box cars has been placed with the American Car & Foundry Co.

## Seek Institute's Suffrages

On the official ballot of the Coal Mining Institute of America for the election of Dec. 7 appear the names of W. C. Hood, assistant general superintendent of mines, H. C. Frick Coke Co., Uniontown, Pa., and R. Dawson Hall, engineering editor, *Coal Age*, for president, only one of whom may be elected.

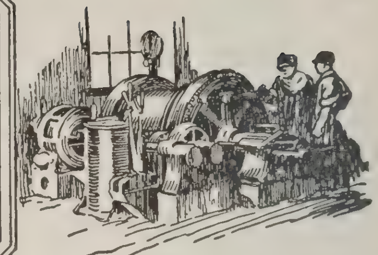
Vice-presidential condidates are: Thomas G. Fear, general manager, Inland Collieries Co., Indianaola, Pa.; A. C. Fieldner, superintendent, Pittsburgh Station, U. S. Bureau of Mines, Pittsburgh, Pa.; J. J. Rutledge, state mining engineer, Baltimore, Md.; A. C. Callen, professor in charge of the mining department University of Illinois, Urbana, Ill.; Frank R. Lyon, operating vice-president, Consolidation Coal Co., Fairmont, W. Va., and N. D. Levin, engineer, mining department, Jeffrey Manufacturing Co., Columbus, Ohio, only three of whom can be elected.

For secretary-treasurer H. D. Mason, Jr., mining engineer, Ebensburg, Pa., and J. J. Maloney, salesman, Goodman Manufacturing Co., Pittsburgh, Pa., are nominated. Twenty names are submitted for managing directors, only ten of whom can be elected. Other names for any or all these offices can be added to the ballot if the voter so wishes.

## C. & O. to Lease 6,000 Cars

Anthracite strike conditions making available an additional supply of empty cars, the Chesapeake & Ohio Ry. will in the near future, it is reported, obtain at least 6,000 idle cars under lease in order to forestall any car shortage. The road, it is stated, has already made application for these cars and it is believed that the order will be approved within a few days. There has been no serious complaint as to the way mines are being served along the Chesapeake & Ohio although certain type of equipment has run short at week-end periods.

# Practical Pointers For Electrical And Mechanical Men



## Changing Location of Arrester Remedies Trouble Caused by Storms

At the Nuttallburg (W. Va.) mine of the Fordson Coal Co. nearly every severe electrical storm caused trouble with the 2,300-volt synchronous motor of the automatic underground substation. This substation is fed by a 1,000-ft., three-conductor, lead-and-armored cable which is carried down through an airway slope. A two-mile pole line extending along the top of the mountain from the head of the slope to the power company's substation is located where it is much exposed to lightning.

Originally the arresters were located on the pole where the armored cable terminates. The choke coils can be seen in Fig. 1. The ground lead of the arrester was connected to the armor of the cable and to a ground wire extending about 150 ft., along the surface, to a connection in moist earth.

### ARRESTERS MOVED AWAY

This did not afford the proper protection, so an attempt was made to remedy the situation. The ground connection was cut loose from the armor and the arresters moved to a point about half a mile from the slope where they were installed on a pole which stands beside a small stream of water. The new location is shown in Fig. 2. Instead of a wire leading down from each line to each respective arrester, strain insulators are used in the line and a loop brought down the pole. The arresters are connected to the bottom of the loops.

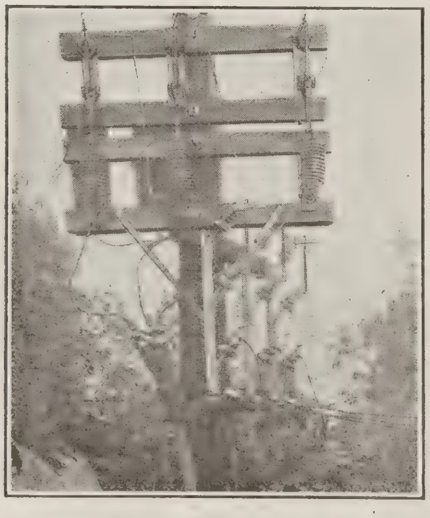


**Fig. 1—Arresters Were Ineffective Here**
The 2,300-volt armored cable which enters a slope at this point feeds an automatic substation inside the mine. Almost every severe electrical storm caused trouble in the substation.

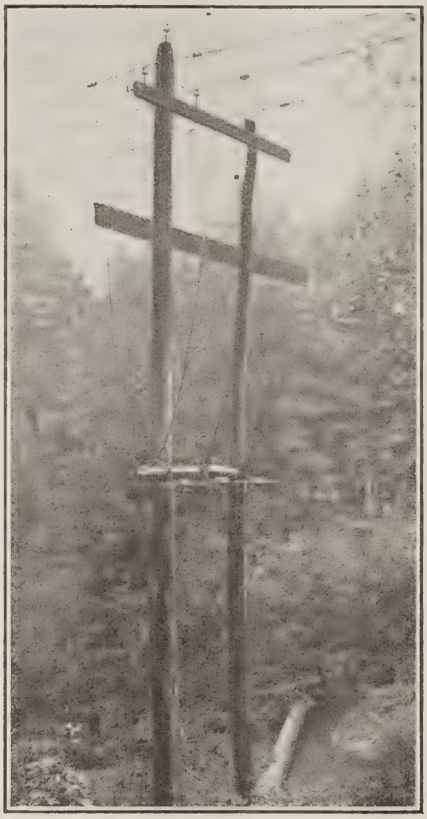

**Fig. 2—Good Grounds Prevent Troubles**
This place is about half a mile from the slope. The line wires loop down to the arresters which are not over 13 ft. from a ground connection made in the stream of water.

Since the location of the arresters was changed many severe electrical storms have visited the locality but have had no apparent effect on the substation equipment.

## Machine Relieves Lathes of Armature Banding

Wherever armatures are rewound in the mine shop they must be banded before the repair job is complete. As a rule such work is done in an engine lathe, this machine being operated in a reverse direction with the back gears thrown in. Banding is thus a process that requires some care and considerable time. If done in an engine lathe it keeps this machine from performing other and possibly equally essential work.

At one of the mines of the Old Ben Coal Corporation down in southern Illinios a special banding machine has been built that completely relieves the shop lathes from this kind of work. This machine is constructed along the general lines of a lathe and operates in a similar manner. The bed is built up of structural shapes and plates, as is also the tail stock. The headstock consists of a worm or spiral reduction gear from an old mining machine. To this gear a small motor is attached. The main shaft on this reduction gear has been provided with a slotted face plate and the end turned to a point or center.

### CARRIAGE NOT NECESSARY

A long threaded shaft extends through the tail stock, its forward end being threaded through a block or nut and its rear end sliding through a similar but unthreaded block provided with a set screw to hold it rigidly in any desired position. The banding wire is held on a spool attached to the wall some distance in rear of the bander. The wire is, of course, passed through a suitable tension. No carriage is required on this machine and motion is transmitted from the face plate to the armature shaft in the usual manner, that is, by means of a single bent or crooked-tail dog.

This bander was comparatively inexpensive to build and performs the work it was designed to accomplish as accurately as could a far costlier lathe. Best of all it relieves the other machines in the shop where it is installed from the time-consuming job of banding armatures, allowing them to proceed with the work of metal cutting for which they are primarily intended.

## Two-Wire Circuits Require Fewer Frogs

An unusual practice but one which has several advantages is that of eliminating trolley frogs and instead using two trolley wires. This practice is followed at the Balkan mine of the Southern Mining Co., at Balkan, Bell County, Ky.

**No Trolley Frog Needed**

From this point to the tipple a feeder would be required if there were but one trolley. The two wires are connected at frequent intervals so that one acts as a feeder to the other.

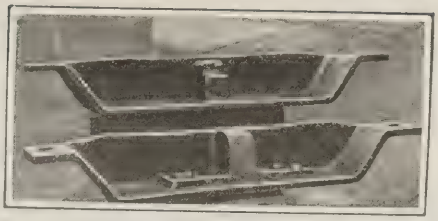
Where two tracks converge at a point from which a conductor of greater carrying capacity than No. 0000 is advisable, two trolley wires are continued a few inches apart. Tie connections are made at frequent intervals. The hanging of the extra trolley wire differs little in cost from the hanging of a feeder on the same supports as the trolley.

Eliminating the trolley frog cuts out delays caused when the pole comes off and also eliminates delays caused by poles being broken when catching in the frog. Torn down trolley wires are also not so frequent. Other advantages of the double-trolley construction are, greater safety to the motormen, and the elimination of the expense of frog renewals.

## Suspension Lugs Are Made Strong as the Bar

While the armature of a spur-geared locomotive is exerting a torque in one direction the field is exerting a torque in the other. The field frame or motor box is kept from rotating by a suspension bar which also supports the weight of one side of the motor. The frequent and sudden starting and stopping of the locomotive imposes severe strains on this bar.

The accompanying illustration shows how, at the mines of a big West Virginia coal mining company the strength of the suspension-bar lugs of the locomotives, has been increased. The upper bar in the illustration is equipped with a type of lug formerly used. It consists of a small block of steel fastened to the bar by two ⅝-in. rivets and also electrically welded around the edges.



**Lugs of the Old and New Types**

The old type lug shown in the upper part of the illustration was the weak spot in these suspension bars. Two angles placed back to back, with a filler between, and attached with rivets and arc welding describes the improved type.

The lower bar has on it a new type lug. This is formed by two short pieces of 4x6x¾-in. angle iron pieces placed back to back, with a ½-in. welded filler between. On each side there are three ⅝-in. rivets, and the whole lug is arc welded around the edges. This lug apparently will stand as much strain as the rest of the bar. A weak detail of construction is thus effectively eliminated.

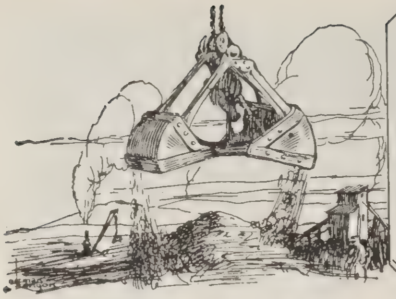
## Use of Colors Simplifies Armature Winding

Cable-reel armatures of the gathering locomotives used by the Island Creek Coal Co. are of the ring-wound type. The work of rewinding these armatures in the company's shop was looked upon as a tedious job, and one in which mistakes were easy to make. The use of colored wire, however, has been found to reduce the chances of error. On a popular type 500-volt armature pictured here there are eighty turns per slot. It is not practical to put on all of these turns at one winding because the space is limited, and if attempted a smooth job cannot be obtained. Consequently, the coils are wound upon the laminations, six turns at a time, that is, all coils which go through one section of the spider are each given six turns. This procedure is repeated until the section is complete.

The large number of coil ends involved makes the work tedious and it is difficult to find the right coil end each time. The work has lately been simplified by the use of magnet wire with two different colors. When an armature is rewound the colors are alternated in the various slots. Before the two colors were adopted errors, whenever made, were due to interchanging the ends of adjacent coils. The use of different colored wires eliminates this chance and saves much time in winding.

**Cable-Reel Armature Wound with Wires Having Two Different Colors Makes Work Easier**

To do a smooth job in the limited space for the winding, the coils must be put on a few turns at a time. It was a tedious and difficult job to select the proper coil ends to complete the winding before the scheme of using two colors was put into use.



# Production And the Market

## Coal Market Develops Halting Tendency Due to Rumors and Mild Weather

A reactionary tendency has appeared in the coal market during the last week, due in large measure to uncertainty brought about by rumors that the anthracite strike is nearing an end. A definite basis for such a belief is rather hard to find in view of the fact that predictions that the suspension will drag until well toward spring are not lacking. Retail dealers and domestic consumers are showing a hesitant attitude, however, compared with the activity of a few weeks ago. The tapering off is still most marked in screened and sized coals, whereas mine-run continues to move quite freely and prices retain considerable firmness. The steam trade is fairly stable, industrials taking full quotas in most instances on contracts, but showing no disposition to increase orders.

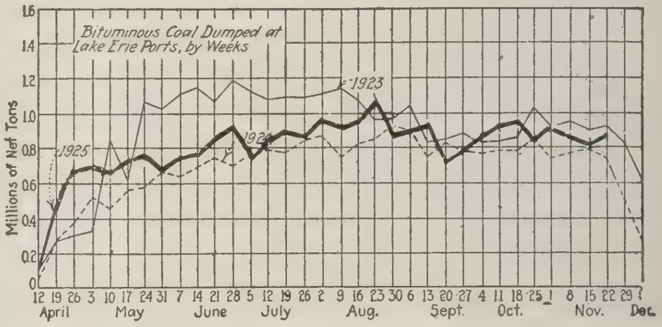
West Virginia smokeless is in less demand in Midwestern markets, dealers in many instances having switched to less costly West Virginia splint and Kentucky grades. Eastern demand for smokeless is still strong, however, though the Pittsburgh district notes a further decline in business from that quarter. Movement from central Pennsylvania is in good volume, but prices on prepared sizes have sagged a little.

Mild weather has been an additional handicap in Midwest producing fields. Franklin County (Ill.) producers have advanced prices 25c. on all sizes, but new business has been scarce and "no bills" are plentiful. The Indiana market is extremely quiet.

Coal traffic through the Cincinnati gateway registered a sharp upturn last week, when 14,437 cars went through, an increase of 1,426 cars over the preceding week and 3,192 over the corresponding week of last year. Headed for the lakes were 2,414 cars, a gain of 311 over the previous week. The trade is faced with the usual disturbing problem at this time concerning the effect of the cessation of lake shipments.

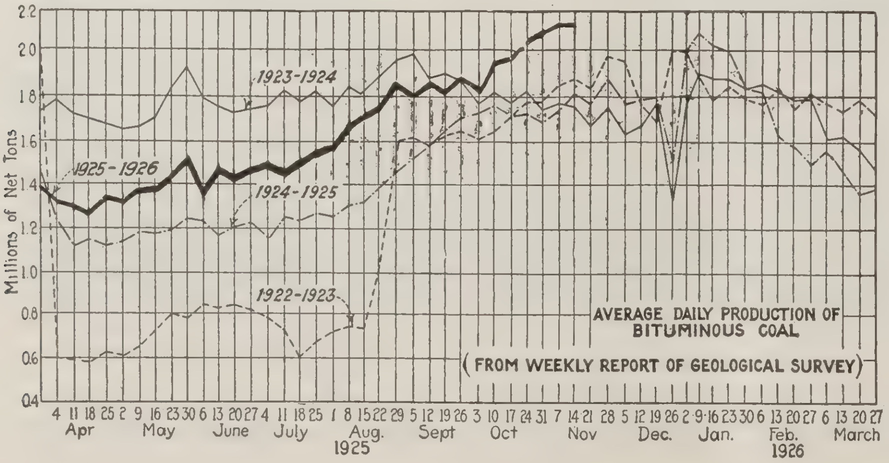
As anthracite has almost totally vanished from the wholesale market and retail stocks are fast diminishing the use of substitutes is likely soon to become general, unless, of course, something should come of the efforts to end the suspension. Coke still seems to have preference, though it has suffered from the mild weather and the restraining influence of strike-settlement rumors.

Output of bituminous coal in the week ended Nov. 14 is estimated by the Bureau of Mines at 12,167,000 net tons, compared with 12,171,000 tons in the preceding week. Anthracite production in the week ended Nov. 14 totaled 32,000 net tons, an increase of 4,000 tons over the previous week.



*Coal Age* Index of spot prices of bituminous coal on Nov. 23 stood at 192, the corresponding price being $2.32, compared with 190 and $2.30 on Nov. 16.

Dumpings of coal at Lake Erie ports during the week ended Nov. 22, according to the Ore & Coal Exchange, were: Cargo, 822,130 net tons; steamship fuel, 40,684 tons—a total of 862,814 net tons, compared with 803,796 tons in the preceding week. Hampton Roads dumpings in the week ended Nov. 19 totaled 332,720 net tons, against 402,152 tons in the previous week.



### Estimates of Production

(Net Tons)

| BITUMINOUS | 1924 | 1925 |
|---|---|---|
| Oct. 31 (*a*) | 10,405,000 | 12,485,000 |

| Nov. 14 (*b*) | 10,466,000 | 12,167,000 |
| Daily average | 1,869,000 | 2,135,000 |
| Cal. yr. to date | (*c*) 412,355,000 | 443,716,000 |
| Daily av. to date | 1,538,000 | 1,650,000 |
| **ANTHRACITE** | | |
| Oct. 31 | 1,444,000 | 18,000 |
| Nov. 7 | 1,592,000 | 28,000 |
| Nov. 14 | 1,674,000 | 32,000 |
| Cal yr. to date | (*c*) 78,920,000 | 61,801,000 |
| **COKE** | | |
| Nov. 7 | 140,000 | 292,000 |
| Nov. 14 | 150,000 | 295,000 |
| Cal. yr. to date | (*c*) 8,372,000 | 8,781,000 |

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Midwest Market Has General Let-Up

In the past week there was a general let-up in the Midwest coal-producing fields. While it was good news that the Franklin County operators had advanced prices 25c. on all grades and sizes, orders have been so scarce that it is doubtful whether southern Illinois operators will benefit. Quite a number of these producers, whenever they have a chance to get an order, are willing to sell at the old prices. Plenty of orders are still booked for 6-in. lump, but there is little demand for egg, and No. 1 Franklin County nut, unless the operator has contracts to take care of this size, is a drug on the market.

The Indiana market is very quiet. Two weeks ago not a car of 6-in. lump was to be had. Fourth and Sixth Vein Indiana coals, which are important in the domestic trade, are again offered freely without any increase in price. There is no demand whatsoever for Fifth Vein coal and operators are cutting each others' prices in an effort to move a few cars of lump coal to take care of the screenings contracts they may have. Western Kentucky coal is again a day to day proposition, all orders having been cleaned up, and prices are not quite as firm. We understand there is considerable consignment coal around again and the operators are willing to take almost any price offered.

While prices on eastern Kentucky and West Virginia stuff are firm, the coa's are offered at such low prices by jobbers who have the coal bought and have it in transit that the consumers, of course, will take any good coal that is offered cheap. Car supply has improved slightly and old orders are being cleaned up, but very few new ones are coming in. The general outlook is not very promising, and it would not be surprising if prices were cut in an effort to move coal.

It seems as if buyers have gone on a strike. Pocahontas lump has been sold recently at $5 direct to dealers, although as a rule the quotations to wholesalers are $5@$5.25. Dealers in many instances have turned to cheaper high-grade West Virginia splint or western Kentucky coal instead of Pocahontas, because the public was unwilling to pay the prices recently prevailing.

The weather has been seasonable in southern Illinois but there was no unusual demand last week in the Williamson-Franklin County field except for lump, and that was on old orders. New orders are not coming in. Egg is beginning to slow up and nut and screenings have been heavy right along. The advance on lump has not taken very well with the country trade and the talked-of increase on egg and nut is not stimulating business as it was hoped it would. The shaft mines are still getting four and five days a week but they all have "no bills" every day and some mines are unable to work occasionally on that account. Railroad tonnage is fairly good. The strip mines are getting good time in and railroad tonnage is good and they are making prices to meet competition from west Kentucky.

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Nov. 23 | Nov. 16 | Nov. 9 | Nov. 24 |
| Index . . . . . . . . . . . . . . . . . . | 192 | 190 | 185 | 170 |
| Weighted average price. . | $2.32 | $2.30 | $2.24 | $2.06 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with repect to the proportions each of slack, prepared and run-of-mine normally shipped, and, second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

In the Duquoin field conditions are similar to those in the Carterville district except in the matter of price. There has been a slowing up in the tonnage moving from this field, however. The Mt. Olive field continues to show activity. This coal is coming into its own because it is a middle grade coal. In the Standard field conditions are bad. Screenings are down, with no chance of them coming up, and there are "no bills" of all sizes at most mines every night and prices bring barely the cost of production. Working time ranges from three to five days a week. Railroad tonnage is reported good. Prices are unchanged.

Domestic trade in St. Louis is fairly active for middle grade and some of the Standard low grade is now beginning to move. High grade Illinois is fair, coke is good, but smokeless and anthracite are slow. Country domestic has slumped off except for cheaper coals and these are moving slowly. Local wagonload steam is good. Carload is fairly good, everything considered, and country steam is unusually quiet. Some coal, both steam and domestic, is moving through to the Omaha market and Kansas City is fairly active. An increasing tonnage is beginning to move northwest to the Minnesota and the Chicago market. No change in prices.

### Kentucky Movement Broadens

It is reported that movement of coal from eastern Kentucky to the lakes has started to slow down, and that stop orders have been placed on unshipped portions of some of the orders. If coal now at the lower end of the lakes is cleared before bad weather stops traffic, the shippers will be lucky. Cessation of lake shipping should release a lot of cars, prevent cars from being held under load so long and materially improve conditions for shippers who haven't been fortunate enough to handle lake business, but it will mean stronger competition for other business.

Domestic coal has been moving quite well to the North, with some movement toward Atlanta, and fair steam business in all sections, including Southeastern textile districts, which are busier than for some time past. Southern movement has been picking up and there has been better waterway shipping as a result of good boating stages. Some Kanawha River coal from West Virginia came into the Louisville market last week, and some shipments have been made from western Kentucky to points on the Mississippi from Memphis southward.

Prices are generally fairly firm all along the line, no changes being reported over the week, except that little eastern Kentucky block coal is moving at over $3.75 a ton, more going at $3.50. Some off-grade stuff can be had at $3.25 and a few specialty coals are moving at $4 or probably a trifle higher. Talk of $4.50 coal, however, is foolish, in view of the grade of coal to be had at $3.50@$3.75. The eastern Kentucky market is graduated down from $3.25 as the low on block, by 25c. stages to $1.25@$1.50 for screenings, mine-run being $1.50@$1.75; nut, $2.50@$2.75; egg, $2.75@$3, and lump, $3@$3.25. Western Kentucky pea and slack is 65c.@85c.; nut and slack, 85c.@$1; mine-run, $1.25@$1.50; nut, $1.35@$1.50; egg and lump, $1.75@$2, and 6-in. block, $2@$2.25.

Continued mild weather is holding back retail demand; the retailers have fair supplies in yards and are waiting for a slump before placing additional business in Louisville.

Car supply continues troublesome, there being plenty of cars apparently, but much congestion at terminals, slow movement and poor distribution.

### Northwest Trade Strong

While lacking the rush during the cold weather of a couple of weeks ago, the Duluth-Superior coal trade is strong, more orders for forward shipment being on hand than in some time. Industrial operations are increasing and business from the Minnesota iron ranges is expanding.

Bituminous coal is still moving this way from the East in larger volume than shipments, so that supplies on the docks are gaining moderately. Stocks of soft coal on commercial docks at Duluth and Superior are placed at around 5,650,000 tons, of which 2,000,000 tons is estimated to belong to the railroads. Twenty-eight cargoes, including one of anthracite screenings, were unloaded at the docks last week and fifteen were en route.

Operators are now limiting anthracite shipments as far as possible to regular customers. Pocahontas and other smokeless coals are being booked in heavy volume by former anthracite consumers, who appear to be satisfied in making the switch. No changes are reported in anthracite quotations on this market and the market in all lines of bituminous except Pocahontas and Kentucky coals is exactly where it stood several months ago.

Pocahontas has been moving up this way more freely and all the docks are now well supplied. Quotations are moderately easier as a result, prepared sizes now running at $8.50@$9; mine-run at $5.25@$5.50 and screenings at $4.25. Domestic coke is firm at $8.50 and briquets are $9. Makers of these substitutes are booking good orders.

Except for industrial demand, which is quite steady, the fuel market in Milwaukee fluctuates with the temperature. Consumers are doing the best they can in the absence of anthracite, and are buying with reluctance and in accordance with weather conditions. Coke and the better grades of bituminous coal are firm at higher prices than usual.

### Southwest Trade Softens

In the last week a slight softening in the Southwestern coal market has been apparent, but operators still report two weeks' accumulation of orders for Kansas lump. Deliveries of Kansas nut are a week slow, the demand for Kansas screenings and mine run being about equal to the supply. There is no surplus of screenings, but there is a more noticeable inclination to shade the prevailing quotation of $2.35 a ton to $2.25 on large contracts.

The coal business in Utah is showing more strength, due to a cold snap, but operators and dealers say it is not what it ought to be yet. The state has too many mines in operation to make business entirely satisfactory except during below-zero weather, which does not visit this region very often. The consumer is not storing coal this winter yet, feeling that there will be plenty of fuel when he needs it. Leading industries such as the metal mines and smelters, transportation, sugar manufacturing and a few others are taking a normal amount of coal, if not a little more. Coal for heating purposes is moving rather well too. Operators report all sizes moving, with the larger sizes the most active. The labor situation is good and prices are as steady as ever.

In Colorado there seems to be no letting up to the increase in demand for domestic coal. Orders are coming from all sections and prices compare with those of the war period. Labor is improving daily and there are no transportation difficulties.

### Movement Heavy Through Cincinnati Gateway

At Cincinnati the closing of lake navigation, chiefly in connection with the car shortage on the Louisville & Nashville Ry., was the chief topic of interest last week. Though the American Railway Association promised 100 per cent car supply, the mines worked only four days. The report of car movement shows that 14,437 loads of coal passed through the gateway, an increase of 1,426 cars over last week, and 3,192 over same week last year. Included in the movement were 2,414 cars en route to the lakes for transshipment via boats. This is an increase of 311 cars compared to last week.

Prices on high volatile remain practically stationary, with the exception of the specialized coals from Elkhorn and Big Sandy as well as those from the Jellico district, which in some cases reached the high point of $4.50 for block. Egg stiffened a trifle and the better grades sold at $2.75@$3 under heavier buying orders from the North, with Canada as the ultimate destination. After a little spurt mine-run has settled back to the old figures of the past several weeks. Screenings and slack are weaker, due to the fact that the lakes, big takers of this, are about through with the late rush. About $1.20 was the week's average figure.

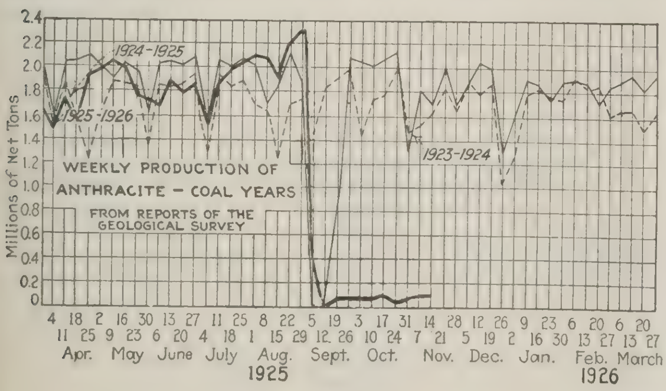
In the smokeless market there has been a crumbling of the high market to the west. The top now is about $5.50 for best Pocahontas lump. New River stuff is selling around $5@$5.25. Mine-run is 25c. off from last week's quotations and shows signs of drooping, while slack, without active byproduct bidding, has slipped 25c. on the range.

Retail business here is much in the same position as for the past two weeks, with no change in quotations. River business holds up well with good shipments going south as far as Louisville.

Softness is developing in some lines of the domestic coal trade in Columbus, due largely to warm weather. Smokeless suffered a decline of about $1 a ton during the week, most customers preferring splints and Kentucky block at much lower prices. Pocahontas has been offered at $5.50 on the local market with few takers, but for other grades of smokeless prices continue rather firm. Retail prices are generally maintained at recent levels.

Buying of steam sizes is spotty and there is no sustained buying to give strength to the market. Large users are pretty well supplied with reserves and consequently are buying current needs only. Quite a few smaller steam users are content to buy on the open market and are thus not entering into contracts. There is little distress coal on the local market, as shipping on consignment is not practiced to any extent.

The only significant change in the eastern Ohio market during the week has been the decided stiffening in the spot price on slack and nut-and-slack of about 15c. per ton in the open market, slack being quoted at $1.50@$1.55 and nut and slack at $1.55@$1.60. The shutting off of lump production for lake shipment has caused a shortage of auxiliary fuel. Railroads continue to take 100 per cent on contracts and additional coal as well, but the rank and file of industry is buying mostly for immediate requirements. The domestic market is dull and retail yards are pretty well stocked. Pocahontas lump is quoted here, f.o.b. mines, $4.75@$5.50, a drop of 50 to 75c. per ton as compared with a week ago.



### Local Demand Stronger at Pittsburgh

In the Pittsburgh market Eastern demand has had only a slight further decrease, while demand from the regular territory has increased a trifle. Railroad demand runs steady and industrial demand has increased somewhat. Demand for domestic coal has increased somewhat. Eastern demand is spotty, running chiefly to egg, for which there also is demand from the North, including Buffalo territory. Prices are very irregular, as sellers get what they can, and must sell. The average is perhaps about $3, but sales last week were at much below and at much above that figure. Otherwise prices are fairly steady and unchanged from a week ago.

Coal loadings in central Pennsylvania are now averaging 3,300 cars a day. Prices on prepared sizes have fallen a little. Operators are inclined to place the blame on retailers in the East who fail to stock up, in the hope that the anthracite strike will end soon. Lump is quoted at $3.75@$4; egg, $4@$4.25; nut, $3.75@$4. Mine-run prices are as follows: Pools 11 and 18, $1.60@$1.80; pool 10, $2@$2.10; pool 9, $2.25@$2.40; pool 71, $2.40@$2.50; pool 1, $2.65@$2.80. Slack is quoted at $1.50.

The bituminous coal trade at Buffalo has sagged off. Local members of the trade who are in the house-fuel industry are trying to make up the loss by selling bituminous lump for $4 or so, mine price, but as a rule the producers want about all there is in it. Bituminous prices are rather weak at $1.60@$1.75 for Fairmont lump, $1.40@$1.50 for mine-run and $1.25@$1.40 for slack; $2.25@$2.50 for Youghiogheny gas lump, $2@$2.25 for Pittsburgh and No. 8 steam lump, $1.30@$1.60 for slack; $1.75@$2 for Allegheny Valley mine-run.

### New England Absorbing Output Better

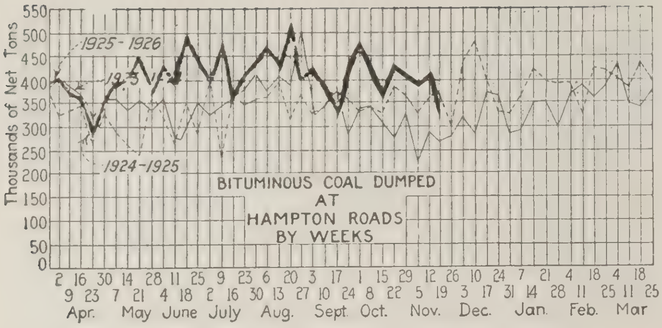
In New England there has been a marked lift in prices of steam coal during the past week. While inquiry has improved only very slightly it is clear that accumulations at the shipping piers are less and that current output is being absorbed in better volume than has been the case heretofore this season. At tidewater there is demand for only occasional cargoes, but on the line and especially in the West the steadiness is impressive. Coastwise movement is only average, and, as usual, the great bulk of the tonnage is being applied either on contract or is shipped to rehandling factors who are closely allied with operating interests.

At Hampton Roads apparently there is more than the usual range of price, the actual level depending upon the individual situation of the shipper. We have heard No. 1 Navy standard Pocahontas quoted at $5.25, while certain of the New River agencies are asserting that for the present their figure is firm at $5.50, in each case per gross ton f.o.b. vessel. Actual sales are reported at as high as $5.40, but at these prices the volume changing hands is as yet relatively small.

For delivery inland from Boston and Providence $6.50 per gross ton on cars seems to be the ruling quotation. Stocks are seasonable in every direction, and no merchandiser of smokeless coals is without adequate reserves.

The Pennsylvania coals via the all-rail route are practically unchanged. Screened lump and egg are being urged on retail dealers, but the tonnage actually absorbed is not large. Prices on prepared have eased off to $5.25@$5.50 in most cases where the grade is good low volatile, and even the Pocahontas and New River shippers have about made up their minds the New England market will hardly stand much in excess of that, with the higher through tariff that applies from N. & W. and C. & O. points. The latter roads are not finding this territory at all easy to manage as to the return of empty cars.

Coastwise freights have firmed recently in response to the demand for transportation for general merchandise to Florida points. This will be an interesting development to watch.



## Mine-Run Moves Easily at New York

Mine-run grades of bituminous coal continue to move easily in the New York market. Industrial consumers are taking full requirements but are not increasing orders. Demand for screened soft coals is good, but not up to expectations. A factor in the situation is the frequent peace rumors emanating from the hard-coal fields and other sections. These invariably are followed by cancellations of orders.

Screened high-volatile coals are quoted at $2.75@$3.25, with quotations for screened low-volatile ranging over the wide range of $4.50@$7. Mine-run quotations continue on the basis of the past several weeks, with practically no change.

At Philadelphia the stoppage of buying in the domestic trade has been felt in the spot market, particularly by concerns handling prepared sizes. In mine-run the effect on prices has been slight, although a decided weakness is evident. While low-volatile producers have felt the decline in buying, the hardest hit are those producing high volatiles. Some sizes which sold at $5 a month ago are easily obtainable now at $3 and under. General business conditions, however, are better, most agree, than at the same time last year.

At Baltimore ordinary trading is somewhat firmer and prices a little stronger, while there has been a distinct drop in the price of prepared sizes as a result of failure to maintain a rush demand for quick delivery of these fuels. Excellent prepared coals are offering to the trade at $5@$5.50 per net ton f.o.b. mine compared with $7 two weeks ago. Mine-run coals of better grade, though not in heavy call, are being influenced by a firmer market, and prices are probably 10c. or so stronger than a week ago. Coke has fallen off sharply, grades that were held around $11 two weeks ago now offering around $7. Two coal loadings were reported from the Custom House on foreign account during the past week.

## Buying Active at Birmingham

Coal buying has been active of late at Birmingham and all mines are pretty well booked up for some weeks. Indications point to a strong and steady market for some time to come for all grades of steam coal and mines are operating full time with a heavy movement. Industrial requirements continue heavy and railroads are using the maximum tonnage on contracts and in some cases more. The movement of bunker coal is much heavier than normal. Many of the high-grade producers of domestic coal are sold up for weeks ahead, although practically all tonnage moving is on spot business booked.

Quotations have stiffened some on steam and domestic grades, Big Seam mine-run being quoted $1.75@$2; washed, $2@$2.25; lump, $2.25@$2.50; Carbon Hill mine-run, $2; washed, $2@$2.25; lump, $3.25@$3.50; Cahaba, $2.25@$2.50; washed, $2.25@$2.75; lump, $4.25@$5; Black Creek mine-run, $2.25@$2.50; washed, $2.50@$3; lump, $4.50@$5; Corona mine-run, $2.50; washed, $2.75; lump, $4; Pratt mine-run, $2.50; Montevallo-Straven lump, $5@$5.50; Montevallo seam, $5.75 per ton mine.

A large tonnage of coke is being sold for consumption at Northern and Eastern points, with a strong, steady market in local territory. Quotations on foundry sizes are $5.50@$6.50 ovens. Gas coke at $5@$5.50 per ton is enjoying an active market.

Operations have suffered some delays on account of car shortage with indications of a more acute situation soon. Operations, especially those in outlying districts, complain of labor shortage also.

## Hard-Coal Substitutes Soon in General Use

Stocks of anthracite in the yards of retail dealers in and around New York City are steadily diminishing and the time is drawing near where the use of substitutes will become general, except in the case of consumers who put in their winter fuel before Aug. 31.

The local harbor contains some boats of independent pea and buckwheat coals, but the movement is not rapid because of the quotations asked. Some retailers are advertising a mixture of soft coal and buckwheat. Some of the larger companies are filling orders and contracts for buckwheat, but are not accepting new orders.

Coke seems to have the inside track in the New York market so far as house owners are concerned and demand has been heavy. The market, however, responds quickly to weather conditions and demand fluctuates accordingly. Quotations for Connellsville run-of-oven coke range $6@$7, with foundry coke quoted $7.50@$8. German byproduct coke, some cargoes of which have reached this harbor, is quoted around $12 gross ton, alongside.

Mild weather at Philadelphia has almost checked the sale of substitute fuels. Few dealers have any hard coal to offer. The dealers' only hope is for a stray car of pea or buckwheat and one is almost as welcome as the other. The storage yards of the companies are almost cleaned up, although there were a few fortunate dealers recently who had the luck to get a car of nut coal. Coke, which ten days ago was selling at $11 and $12 at the ovens, is now obtainable at a reduction of $3.

Baltimore hard-coal dealers are devoting their attention to selling prepared sizes of bituminous, but this is confined to demands from consumers who failed to lay in any anthracite stocks. Dealers here did not enter into competitive buying with those cities which bought up the greater part of the reserve stocks of anthracite at the mines after the strike started.

At Buffalo the supply of small anthracite sizes is giving out, so the soft-coal trade will soon be the whole thing, it seems. Coke of good quality can be had, though some of it is not up to the average appearance. It will no doubt burn, though. The only prospect of relief in this direction is that the production of coke is increasing fast and as soon as high-priced sellers get caught up with their orders they probably will find prices so reduced that they will have to come down too.

## Connellsville Coke Market Sags Further

The Connellsville coke market has declined further. Eastern demand has continued light. As recent selling was only for prompt shipment, every day has brought additional occasion for producers to sell, and this by itself weakens the market. Realizing the situation, some operators began more than a week ago to restrict production, not by putting out ovens but by lengthening the coking time.

The market is now quoted in the trade at $5@$5.50 for regular run-of-oven blast-furnace coke, but offerings at $5 go the rounds to such an extent that there is little justification for quoting a market range above that figure. Some offerings to blast furnaces have not been taken up, though it seems quite possible that if coke continues weak furnaces will buy some spot or prompt lots for reserves. As their contracts are chiefly at around $3 they receive no more on contract than is absolutely essential.

Blast furnaces are not disposed to negotiate for first-quarter coke. They assume that coke will be much cheaper in March than in January, whatever actual prices may be, hence they can buy for January alone, or bank for that month.

Foundry coke is off 50c. in sympathy, being now quotable at $6.50@$7.

## Car Loadings, Surplusages and Shortages

# Foreign Market And Export News

## British Coal Market Develops Stiffer Tone Due to American Demand

The outstanding feature of the Welsh steam coal trade of late has been the substantial development of American demand. The Americans required anthracite, but the Welsh anthracite collieries were overbooked already and were unable to accept further business. Dry steam coals are an excellent substitute for anthracite and purchases are on a considerable scale, steamers having been chartered representing shipments in the course of the next ten days of at least 50,000 tons from Cardiff. This business has had a stiffening effect on the market for dry steams, but other trade has been quiet.

Apart from drys, prices show further relaxation for all classes of large, especially Monmouthshires. Small coals are somewhat steadier. It is hoped that weather conditions will soon permit of the regular arrival of steamers and enable arrears of shipments to be overtaken, so that the coal trade as a whole can settle down on a steadier basis. Outlook for Welsh steam coals is more favorable.

The collieries in Durham and Northumberland are heavily booked for a few weeks ahead, some to the end of the year. Therefore, work is proceeding steadily at the pits and docks. Inquiry too is promising. Cargoes continue to be bought for shipment to America, Mediterranean business is on a larger scale and so are shipments to the coaling stations. Prices are firmly held and slightly higher for all November shipments. All classes of coke are in good demand and poor supply, with little available to sell for November delivery. Gas coke is firm and higher. Contract business at the moment is quiet.

Production by British coal mines during the week ended Nov. 7, according to a special cable to *Coal Age*, totaled 4,790,000 gross tons, compared with 4,835,000 tons in the previous week.

---

## French Industrial Coal Trade In Fair Position

The French coal market is in a fairly good position, especially in the matter of national products, as industry has improved and is demanding more, and foreign coals can easily be displaced by those of France because of the depreciation of the franc. An instance is seen in the case of Swansea anthracite, import quality, first choice, which recently was priced at the prohibitive figure of 410 fr. at Rouen.

Although consumption of domestic coals has been light lately because of the mild weather, dealers are still restocking sized products. French nuts in all categories are still scarce, deliveries from the mines being dilatory. In the Parisian area retail prices were not changed Nov. 1, except for an increase of 15 fr. per ton on anthracite nuts from South Wales to 520@535 fr., and 10 fr. on cobbles, at 480@500 fr.

Complaints about the tardy arrival of empty wagons at the mines have almost disappeared and freight is unchanged.

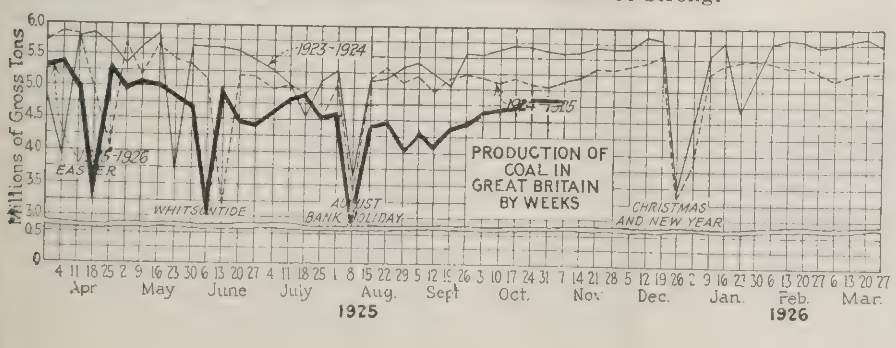
Receipts of indemnity fuels from the Ruhr during the first twenty-four days of October included 330,500 tons of coal, 185,200 tons of coke and 23,900 tons of lignite briquets. On reparation coals, the prices of anthracitic sized, dry and semi-bituminous for domestic uses on Nov. 1 were advanced 10 fr. and those of lignite briquets 5 fr. per ton.

During October the O.R.C.A. received from the Ruhr 227,450 tons of coke and in the first three days of November it received 11,646 tons.

## Tendency to Drag Hits Trade At Hampton Roads

The coal business at Hampton Roads began to drag somewhat last week, with the market holding its own fairly well though demand scarcely normal. Inquiries for foreign business were dropping off and bunker trade was only fair.

Domestic trade occupied chief attention in the business, with soft coal retailing at $13 a ton, and anthracite very scarce at $16.50 and in some cases more. Coastwise business was fair, but all-rail rates through to New York and New England were still having a tendency to weaken the demand for coastwise shipments. The tone of the market was not strong.



## Belgium Faces Foreign Menace

The Belgian industrial coal situation is still extremely strained; in the Borinage district the effects of the low rate of French exchange are beginning to be evident and British competition does not slacken. New concessions are noted on the prices of bituminous coals and coking smalls.

In domestic coals the tendency remains firm and certain sellers are slightly inflating prices. Some dealers seem to wish to force their French clients to pay in Belgian francs, which the latter absolutely refuse to do.

---

## Field and Trade

### ALABAMA

The Alabama By-Products Corporation has resumed operation of its Clipper Mine, located near Dora, Walker County, which had been on the idle list for some time.

A new slope mine is being developed by the Brookside-Pratt Mining Co. at its Warrior River operations, in Walker County, near Carbon Hill, which will increase the daily output of prepared coal to between 1,500 and 2,000 tons. In order to handle the increased tonnage new jigs are being added to the washery and the tipple capacity is being enlarged. The coal from the new opening will be brought out on a conveyor belt to the tipple. The entire plant has been electrified and additional electric locomotives will be added to the inside haulage. The head offices are located in Birmingham.

The Sloss-Sheffield Steel & Iron Co. has started up its Ivy Mines, near Dora, which had been idle for some time. Its coal and coke requirements have been increased by the blowing in of another furnace. Domestic coal, for which there is a good demand, also is produced from this operation.

### COLORADO

The Pikeview mine of the Pikes Peak Fuel Co. was again operating Nov. 10 at normal capacity, with all men back at work, following a one-day walkout. The decision of the men to return to the mine followed a compromise between the miners' demand for a return to the 1919 scale and the operators' proposed wage reduction to approximately the 1917 scale. The new scale gives day laborers $5.75, machine miners will receive 61c. a ton on production, while pick miners will continue to receive 76c. a ton on a contract basis. The company's former wage gave laborers $5.25 a day, machine miners 57c. a ton, while the pick miners were not affected.

### IDAHO

Coal shipped to Boise City over the new railroad is selling at $13 per ton, while last year the same grade of coal freighted in by trucks retailed at $23 per ton.

### ILLINOIS

The Assumption Coal Co., with a capital of $150,000, has been incorporated and will begin operation of the mine at Pana, which has been idle for more than a year. The incorporators are: O. D. Hedrick, C. C. Cazalet and M. J. Fitzgerald.

Preliminary work has been started for the opening of Mine No. 7, of the Peabody Coal Co., at Kincaid. The mine has been closed since May, 1925. When operating at capacity it gives employment to over 900 men.

The Weaver mine of the Old Ben Coal Corporation began work Nov. 4, after having been idle since last February. When this mine is working at full force its payroll runs from $75,000 to $80,000 a month. The mine is served by the Illinois Central and the Chicago, Burlington & Quincy railroads. With the recent resumption on full time in the No. 7 mine of the Consolidated Coal Co., at Herrin, and the reopening of the Weaver mine, only three large mines in Williamson County will be idle. These are Consolidated No. 8, at Clifford, and two Old Ben mines known as the West mine and No. 18, in Johnston City.

### IOWA

C. W. Duro, Des Moines, has acquired the interests in the Madrid Coal Co. owned by W. H. Evans and H. E. Evans, of that city, placing practically all of the stock in that company in possession of three men, Mr. Duro, E. O. Preston and C. W. Springer. Mr. Duro is now connected with the Great Western Coal Co. and Mr. Preston and Mr. Springer are the owners of the Beaver Coal Co., Des Moines.

The Central Iowa Fuel Co. began the sinking of a new shaft Nov. 2 about six miles northeast of Chariton, on the Peter Lawson farm. The mine is fitted with all modern equipment. As it is only a short distance from the Olmitz and Tipperary coal road, the expenditures for track extension will not be great.

### KANSAS

The first Kansas chapter of the Joseph A. Holmes Safety Association was organized in West Mineral Nov. 10 and was named the "James Sherwood Chapter," in honor of the state mine inspector. It starts with twenty charter members. Formation of other chapters throughout the district will be pushed as rapidly as possible.

Two hundred Kansas coal operators, men in other phases of the industry and representatives of insurance companies at a dinner in Pittsburg on Nov. 12 discussed means for reducing liability rates, which operators assert have reached an exorbitant level in this field. Insurance representatives expressed the belief that rates might be lowered if proper effort were put forth by the companies to promote safety of employment and also guard against fraudulent claims. Increase in insurance rates from $3.40 per $100 payroll to $6.40 since the compensation law went into effect was attributed by operators to fraudulent claims.

Nineteen of 150 union coal miners, who last summer refused to return to work when operators of local mines issued an ultimatium suspending the wage scale then in force, returned to work and accepted a $5 a day scale, C. N. Fish, manager for the Home Riverside Mining Company, has announced. Fish said he expected more of the miners to return in the next few days.

The Kansas mining district had 238 mines working in early November, an increase of 103 over the same time last year, according to figures compiled by James Sherwood, state mine inspector. As this includes a number of "dinky" mines, working only a few men each, the total of employees is not proportionately increased, but it is estimated that 6,000 miners are now working, compared with slightly more than 3,000 a year ago. A number of large mines have swung into action this fall after being idle two or three years. For the first time in three or four years a majority of the "dinkies" are working. Inspector Sherwood predicts that tonnage figures for November and December will set a high record for recent years and that the 1925 total will be substantially larger than the 4,491,069 tons in 1924.

John R. Stanley, of Rocky Ford, Colo., recently recorded a coal lease option on Montgomery County land near Independent. While this option covered only 80 acres it is reported that Stanley has taken options on 3,000 acres south and east of Independence. Reports from Independence state that a railroad company is interested in the project and is backing Stanley. A few months ago the Pittsburg-Midway Coal & Mining Co. took leases on thousands of acres in Labette County, adjoining Montgomery County, for the Missouri-Kansas & Texas Railway Co.

A referendum election on moving the headquarters of District 14, United Mine Workers, from Pittsburg is indicated for an early date, district officials state. Arma has made an offer of $18,000 cash toward erecting a headquarters building in that town and Frontenac has offered to give a theatre building, valued at $50,000, which can be remodeled for offices.

William Harkes, general superintendent of the Central Coal & Coke Company during a visit to Pittsburg on Nov. 11 directly denied a persistent report that the Central is preparing to reopen its mine No. 50. The two mines it is now operating have a daily production of 2,000 tons, he said, which is ample to meet present market conditions. The Central's mines in the district other than the three referred to are being operated under subleases.

A proposal to subscribe to blanket insurance for all members of District 14, United Mine Workers, soon will be submitted to a referendum vote by district officials if no opposition to the plan develops in response to an inquiry sent locals by district officials Nov. 14. The proposal is for a blanket policy of $500 a man, to cost between $1.10 and $1.15 a month each. The plan has the approval of district officials, but a referendum will be necessary to add a clause to the district constitution authorizing the executive board to purchase the insurance.

A new shovel mine will be opened soon near Mulberry on 160 acres of land leased from J. G. Miller and Miss Ada Miller by a group of men headed by E. M. Roberts, of Pittsburg. Other members of the company are Frank Thomas, of Mulberry, and Hy McCullough, Boyd Spencer and H. H. Hughes, all of Pittsburg. The coal is in a 38-in. seam, from 10 to 20 ft. from the surface. A caterpillar type steam shovel has been ordered by the new company.

## MICHIGAN

Receivership for the Cooper Coal Co., organized to operate coal mines in Saginaw and Shiawassee counties, was asked in an action brought last week in Circuit Court at Saginaw by John Winship, who alleges there is $3,425 due him on a note brought from William Carmichael securing a loan made to the company.

## MINNESOTA

An extra 25c. delivery charge on consumer deliveries in the outskirts of Minneapolis and St. Paul, which has been in force for some years, has been absorbed. When it was made it was because of the long distance from the coal yards to the outlying sections. But the coal business has been decentralized, and coal yards exist within a mile or so of every section of the city. The change was made through the influence of the Twin City Coal Exchange.

The Pittsburgh Coal Co.'s No. 1 dock, one of the landmarks at Duluth, is being dismantled. It was built in 1881 by the Ohio Coal Co. and later was taken over by the Pittsburgh Coal Co. In 1895 the old wooden bridges on the dock were replaced with six new steel bridges and in 1897 two additional steel bridges were built. Power was supplied from a central steam plant of five 100-hp. boilers. In its day the plant was regarded as one of the most efficient at the head of the lakes, having a daily average capacity of 4,000 tons in unloading vessels. It had been out of commission since 1917, the Pittsburgh interests having built a modern new dock.

## OHIO

Operations were resumed at the Lincoln mine of the Lorain Coal & Dock Co., at Lansing, about three miles west of Bridgeport, on Nov. 9. The mine had been idle since November, 1924, owing to a fire which had raged for several weeks. Within a short time it is planned to have about 500 men at work.

Work of cleaning up the Fort Pitt mine, just across the river from Moundsville, W. Va., was started during the week beginning Nov. 9, and operations will be resumed within a short time. This mine when operating employs about 300 men. It has been closed down for about a year. A few weeks ago the tipple was destroyed by fire but repairs that will permit operation can be made quickly.

Dumpings at the Toledo docks of the Hocking Valley Ry. for the week ending Nov. 18 totaled 201,912 tons, as compared with 230,502 tons during the corresponding week last year. The loadings at the docks during the present season up to Nov. 18 were 7,857,230 tons as compared with 6,371,138 tons in the corresponding period of 1924.

Attorneys Harry B. Arnold and Francis J. Wright have entered suit against 53 coal companies, which held membership in the Southern Ohio Coal Exchange, of Columbus, for legal services performed in fighting the so-called Ohio-Michigan case for railroad rate adjustment before the Interstate Commerce Commission. The Southern Ohio Coal Exchange was forced into the hands of W. W. Metcalfe as receiver about eight months ago and has been in process of liquidation.

Arrangements have been made to start mines Nos. 5 and 7 of the New Pittsburgh Coal Co. in about two weeks which will add materially to operations in the Nelsonville section of the Hocking Valley.

The Jacksonville mine of the Essex Coal Co., the largest of the company in the vicinity, has been opened following an idleness of almost a year. The announcement is made that the mine is opened on the Jacksonville scale. The same company is operating several mines in the Pomeroy Bend field on the 1917 scale basis.

Secretary G. W. Savage of the Ohio division of the United Mine Workers has issued a statement in which he attempts to show that mining conditions have improved materially in the Hocking Valley and southern Ohio field. He said that 60 per cent of union miners are now employed on the Jacksonville scale as compared with 30 per cent during the summer months. About 700 to 800 men are working in the Sunday Creek section of the Hocking Valley but there is not much activity in the remainder of the field. Several mines near Cambridge have been reopened and a half dozen in Columbiana and Jefferson counties have resumed.

## PENNSYLVANIA

Last-minute decision not to open the East End mine of the Chartiers Creek Coal Co., near Canonsburg, probably was due to the decline in the market. The mine was to have opened on the Jacksonville scale.

Preparations are being made to start coal stripping operations in Baggaley. John I. Irwin, who recently bought the land, has shipped a steam shovel to the operation.

John C. Graham, of Butler, has been elected a director of the Standard Coal & Coke Co., of Chicago. Mr. Graham has been producing coal in the Pittsburgh district for 10 years.

Dismissal of the petition filed Nov. 5 by Harry F. Sinclair, oil man of New York, to intervene in the proceedings between the Harrison National Bank of Cadiz, Ohio, and the Carnegie Coal Co., was asked at Pittsburgh Nov. 18 in an answer filed by the coal company, which branded Sinclair's action as superfluous, impertinent and scandalous. The oil man asked the court to replace the two receivers of the coal company. Sinclair brought suit for $125,000, which he seeks to recover on a promissory note he claims he indorsed in favor of R. B. Haverstick, treasurer of the coal company. The company's answer asserted the retention of W. M. Wilshire and C. G. McGregor is necessary to the operation of their mines.

Machinery at the Oakdale mine of the Carnegie Coal Co. was damaged considerably last week by vandals who were under the impression, it is believed, that the mine planned to start on the 1917 scale.

The Bethlehem Mines Corporation, which is endeavoring to operate the Marianna mines, near Bentleyville, on the 1917 scale, is experiencing considerable trouble in getting production started, it is learned. Snipers are firing shots at spasmodic intervals at the tipple, and windows in the power house have been broken. Early last week one man was arrested by state police. Operation plans of the company are behind schedule.

The Glen Alden Coal Co., Scranton, one of the largest anthracite companies, deferred action on its semi-annual dividend at the regular meeting Nov. 10. No statement was forthcoming from the directors following the passing of the dividend. A rate of $3.50 a share was inaugurated in May, 1924.

The Pittsburgh Terminal Coal Corporation reports net income of $173,177 for the September quarter, after all expenses and reserves for depreciation, depletion and other deductions. After preferred dividend requirements, this is equal to 94c. a share earned on the 120,000 shares of capital stock outstanding, against 22c. a share earned in the previous quarter.

## UTAH

H. C. Marchant, general manager of the Superior-Rock Springs Coal Co., with headquarters in Ogden, has been appointed assistant to P. J. Quealy, president of the Kemmer Fuel Co. Hereafter he will have his headquarters in Kemmerer, Wyo., except that for the next few months he will be in Denver, Colo.

## WEST VIRGINIA

The West Virginia Coal & Coke Co. has resumed operations at its mines and ovens at Junior, in Barbour County, and now has 52 ovens in blast there. All the plants of the company where there are coke ovens have now resumed work, and owing to the large amount of tonnage required for the burning of coke, the company is operating all its mines except one on a full-time basis. Before resuming work at Junior it was necessary to rebuild a tipple at that place, the old one having been destroyed by fire several years ago and never having been rebuilt owing to the poor demand existing for coal during the last few years. Approximately 150 men are being given employment at the Junior plant.

All coal loading records of the Norfolk & Western Ry. were broken in October when the total number of cars loaded with coal in all districts on the line reached 79,397, 3,391 more than were loaded in September. A new high record for weekly coal loadings was established in the last week of October, when 18,369 cars were loaded as against the previous high record of 18,145, made during the week ended Oct. 10.

J. T. Dunigan, president and general manager of the Coal River Collieries Co., announced that October production, 66,185 tons, was the largest in the history of the company. All of the mines of the company are now operating and arrangements are being made to open a new mine at Plant No. 2, in the Cedar Grove seam. This operation is now producing 150 tons daily and within 30 days the capacity of 300 tons will be reached. The Southside mine, at the same operation, in the Lick Creek division, will be opened soon.

## CANADA

Charles Murphy, general manager of the Western lines of the Canadian Pacific, says little or no coal is going into Manitoba from the south, and that nearly all the domestic fuel is being shipped from Alberta. As a matter of fact, it is being shipped as far east as Chapleau, in Ontario, 375 miles east of Fort William. Ninety per cent of the coal in Winnipeg, he said, came from Alberta. "I think there is no question of the market being maintained if good quality coal is shipped," he remarked. Mr. Murphy said that the railway put in heavy supplies of steam coal before the grain movement began, in order that equipment might be utilized. The company, however, was still taking from 3,000 to 4,000 tons a day.

# Traffic

## Cancellation of Joint Rate Is Upheld

Proposed cancellation of joint rates on anthracite from Lake Erie and Niagara frontier junction points to Sparland and Henry, Ill., has been upheld by the Interstate Commerce Commission in a mimeographed report on Coal from Erie, Pa., etc. The cancellation of these rates will leave in effect a combination on Chicago $1.14 per gross ton higher. The combination on Chicago is the usual basis of rate construction in this territory. Respondent carriers justified the cancellation on the non-compensatory character of the joint rates.

## Coke Rate Situation in Tangle

The rate situation on coke to the Middle West has been further complicated by the action of the Interstate Commerce Commission in revoking the permission it recently gave Alabama roads to establish rates to southeastern Michigan 50 and 75c. per ton over the Chattanooga basis on short notice. Tariffs filed to become effective Nov. 13 were rejected on the ground that certain provisions would conflict with the long-and-short haul section of the Act to regulate commerce.

Permission to establish these rates on short notice had been granted in the first instance on representations that there was a need for such movement because of the shortage in domestic fuels created by the anthracite strike. These representations were challenged by byproduct plants in Illinois and Indiana, which declared that they could take care of the market in question. At that time the protestants asserted that demand from retailers for household fuel was by no means taxing oven capacity.

Another proposal before the Commission affecting the coke adjustment in Central Freight Association Territory is that made by carriers serving byproduct plants in western Pennsylvania. These railroads propose to reduce rates from Clairton, Bessemer, Wylie, Glassport and Pittsburgh to points in Pennsylvania, Ohio, Michigan, Indiana, New York and Ontario 10 to 88c. per ton, widening the present differential of 15c. under Connellsville to as high as 63c. in some cases. Protest has been made by the Coke Producers' Association of Connellsville, which sets up that the rates proposed would disrupt rate relationships which have existed for years, would give undue preference to Clairton and unjustly discriminate against the beehive ovens.

## More Rates on Coke Approved

Additional tariffs naming reduced rates on coke for intrastate movement have been approved by the Public Service Commission of New York. Interest in the rate adjustment has been heightened by the domestic demand for coke created by the anthracite strike. The new rates and routes approved are:

Buffalo, Rochester & Pittsburgh Ry., Charlotte to Rochester, 80c. per net ton; Charlotte to Garbutt, Mumford, LeRoy, Scottville and Wheatland, $1.39; to Pavilion, Rock Glen, Warsaw and Wyoming, $1.51; to Perry and Silver Springs, $1.89; effective Nov. 10.

Genesee & Wyoming R.R., Caledonia, Retsof Jct., P. & L. Jct. and Greigsville to Fraser, Greigsville, Halite, Inverness, Retsof, Taylor and York Center, 72c.; effective Dec. 10.

Lehigh Valley R. R., Buffalo, East Buffalo and Harriet to Elmira (including points on D. L. & W. and Erie railroads where switching charge does not exceed 38c. per ton), Elmira Heights, Horseheads, Breesport, Erin, Park Station and Swartwood, $2.14; effective Dec. 7.

New York Central Lines, Charlotte to Rochester (Kent St. and Portland Ave.), 80c.; effective Nov. 7.

## Chicago District Fight Revived

Rates on bituminous coal to points in the Chicago switching district are again before the Interstate Commerce Commission in a complaint filed by the Illinois Coal Traffic Bureau attacking the rates from mines in Illinois. The adjustment of rates to this vast industrial and domestic coal-consuming district—sharing with Pittsburgh the distinction of being the largest coal-consuming areas in the world — has been before the Commission in one form or another for several years. Rates from Indiana mines to the Chicago district and to all points in Illinois and Wisconsin have been put in issue in complaints filed by the Indiana Bituminous Coal Operators' Association.

# Obituary

**Thomas Griffiths,** superintendent of the Wolf Den Coal Co., Shallmar, Md., since 1917, died at the home of his son-in-law and daughter in Cumberland, Md., on Nov. 14th. He had been in ill health for about two years but had apparently fully recovered when he suffered a relapse two months ago. Mr. Griffiths was well known to mining men in Pennsylvania, Maryland and Virginia, in all of which localities he operated for some of the largest companies, among which were the Rochester & Pittsburgh Coal & Iron Co., Berwind-White Coal Mining Co. in Pennsylvania and the Houston interests in Virginia.

**Samuel E. Stimmell,** 47 years old, for the past 12 years superintendent of the Export mines of the Westmoreland Coal Co., died in his home in Export, Pa., from typhoid fever last week. Mr. Stimmell was a mining engineer. He leaves his wife and two children.

**A. E. Moore,** aged 65, a prominent coal operator, died at his Columbus (Ohio) home recently, following a short illness. He had been a resident of Columbus since Oct. 1, when he moved from Charleston, W. Va., but had spent the greater part of his younger days in the Buckeye capital. At the time of his death he was connected with the Indian Coal Co., of Charleston, and was formerly president of the Hocking Valley Mining Co., of Athens; the Orange Gas Coal Co., of Athens, and the Coal Valley Mining Co., of Charleston. He is survived by his wife, a son and a daughter.

## Coming Meetings

**American Society of Mechanical Engineers.** Annual meeting at New York City, Nov. 30-Dec. 3. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**Fourth National Exposition of Power and Mechanical Engineering.** Nov. 30 to Dec. 5, at Grand Central Palace, New York City.

**Smokeless Coal Operators' Association.** Annual meeting, Dec. 10, at Washington, D. C. Secretary, E. J. McVann, Washington, D. C.

**Coal Mining Institute of America.** Annual meeting, Dec. 9-11, Pittsburgh, Pa. Secretary, H. D. Mason, Jr., P. O. Box 604, Ebensburg, Pa.

**American Mining Congress.** Twenty-eighth annual convention, Dec. 9-11, Washington, D. C. Secretary, J. F. Callbreath, Munsey Bldg., Washington, D. C.

**American Wood Preservers' Association.** Annual meeting, Jan. 26-28, 1926, at Cleveland, Ohio. Secretary, E. J. Stocking, Chicago, Ill.

**Coal Club of Philadelphia.** Annual meeting, Jan. 28, 1926, at the Bellevue-Stratford Hotel, Philadelphia, Pa. Secretary, C. K. Scull, Philadelphia, Pa.

## New Companies

**British American Coke & Byproducts, Ltd.**, has been incorporated with a capital of $10,000,000 to mine, produce and deal in coal, coke and other fuels, with head office in Toronto, Ont., by Walter B. Kingsmill, Stanley S. Mills, Vincent W. Price and others.

**The H. T. W. Coal Co.** of McCarr, Ky., with a capital of $20,000, has been incorporated by John S. Hall, and J. W. T. St. Clair, both of Williamson, W. Va.

**The Cleveland Collieries Co.**, Cleveland, Ohio, has been chartered with an authorized capital of 600 shares, no par value designated, to operate coal mines and properties. Incorporators are B. D. Gordon, Samuel S. Rosenthal, A. J. Schanfarber, C. R. Berne and E. L. Mueller.

**The Macksburg Mining Co.**, Byesville, Ohio, was recently incorporated with a $10,000 capital to mine and deal in coal. L. J. Swoll, H. P. Muhlbch, E. Delille, E. Waers and George Ruskin are the incorporators.

**The Acme Coal Mining Co.**, with a capital of $50,000, has been incorporated by S. J. Peters and Arthye H. McLain, Parkinson Bldg., Okmulgee, Okla.

## Industrial Notes

**Foote Bros. Gear & Machine Co.**, Chicago, Ill., is now manufacturing Sykes gears for use in IXL continuous tooth herringbone gears and speed reducers, having installed Farrel-Sykes machinery for the purpose.

**W. J. Rainey, Inc.** has opened a sales office at 328 and 329 Oliver Bldg., Pittsburgh, Pa., for the sale and distribution of "Rainey" products in the Pittsburgh district. This office is in charge of William Firth, for several years Pittsburgh manager of the Whitney-Kemmerer Co.

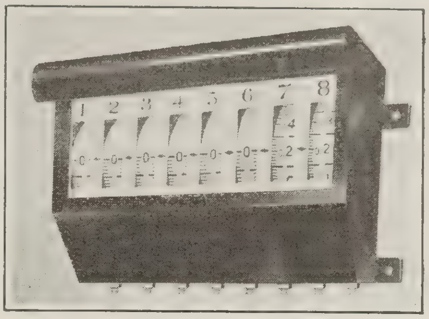
At the last meeting of the board of directors of the **Linde Air Products Co.** G. W. Mead, formerly president, was elected chairman of the board and W. F. Barrett, formerly vice-president, was elected to the presidency. In addition to these changes R. R. Browning was elected vice-president in charge of sales activities and J. A. Rafferty, vice-president in charge of engineering manufacturing and research.

At a recent meeting of the board of directors of the **Prest-O-Lite Co., Inc.**, M. J. Carney, formerly president, was elected chairman of the board; William F. Barrett, formerly vice-president, was elected to the presidency; Ralph R. Browning was elected vice-president in charge of acetylene sales activities and R. J. Hoffman was re-elected vice-president in charge of storage-battery and automotive divisions.

# New Equipment

## Multiple-Dial Draft Gage Aids In Boiler Control

In most boiler installations if continued high efficiency is to be maintained it is essential that the fireman should know accurately the draft intensity existing not only in the breeching or stack but also in the ashpit, above the fire and if possible in each pass of the boiler. Heretofore it has been necessary in most cases to employ a separate gage for each pressure desired. In order to make all of these various readings discernible at a glance as well as to render them continuously comparable one with the other the Republic Flow Meters Co., of Chicago, is introducing the instrument shown in the accompanying illustration.



**It Tells the Whole Story**

With this new multiple-dial draft gage before him, the fireman can see at a glance the draft intensity in breeching, stack and ashpit as well as above the fire and in each pass of the boiler—and he can compare them readily.

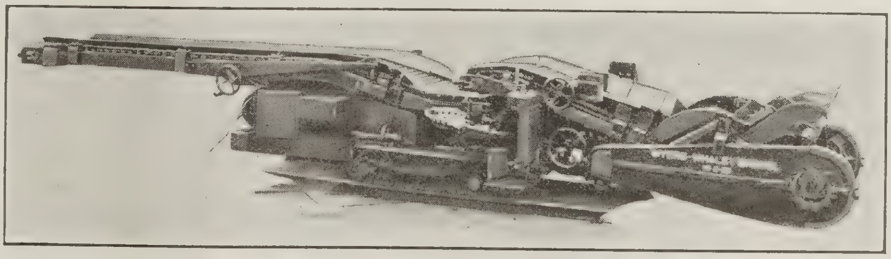
This meter is made in various sizes with units ranging from three to twelve in number. It may be placed in any convenient location, usually on the front of the boiler, each component unit being connected to the point in the boiler setting where a reading on the draft is desired. An electric light housed within the curved reflector spanning the top of the instrument illuminates all of the dials uniformly and makes them easy to read and compare.

In construction this instrument is simple. One leg of a U-tube containing a non-volatile oil is exposed to the pressure to be measured. The other leg of this tube contains a counterbalanced float, which in rising and falling actuates a gear quadrant meshing with a pinion the shaft of which carries a rotating dial. The dial somewhat resembles that of a speedometer, its readings possessing equally easy legibility. By placing the dials connected to the various points of the setting in sequence not only may the actual pressures or vacua be read directly but the relative differences between adjacent points, such as the boiler passes or the wind boxes of the stoker are at once apparent. Any marked variation from normal in these relative values indicates a change of condition within the furnace that requires investigation and usually correction. Thus the instrument aids in obtaining high efficiencies.

## This Shoveling Machine Will Work in 48-In. Coal

In order to meet the almost insistent demand for a coal loading machine that could be used in a headroom of 48 in., the Myers-Whaley Co., of Knoxville, Tenn., has recently placed on the market the loading machine shown in the accompanying illustration. This is known as the No. 2-25 underground shovel. It has a total length of 23 ft. 10 in., a width overall of 5 ft., (when the operator's seat is removed, 4 ft. 6 in.). The total height overall (traveling height) is 3 ft. 3 in. above the rail. The reach of the shovel is 8 ft. 6 in. on either side. The width of the shovel itself is 33¾ in., outside measurement, and the capacity of the machine is 34 cu.ft. per minute in loose material. Its weight is approximately 14,000 lb.

This machine will operate in a minimum height of 42 in. above the rail and can travel through places having a minimum clearance above the rail of 39 in. The first machine of this type is now in service in central Pennsylvania and shows an actual capacity equal to that of the regular No. 3 shovel, but since it is 6 in. lower than the No. 3 it can operate in that much less headroom. It is also capable of traveling through old workings or restricted passages in the mine which would be too low for the other machines to negotiate. It does not replace any of the other sizes now made.



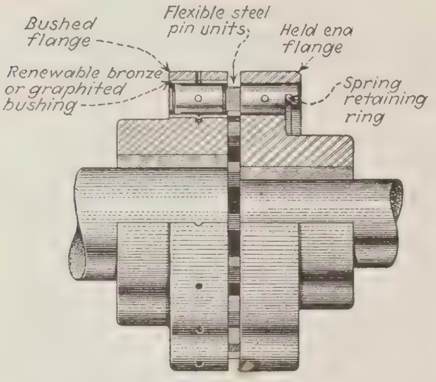
**Sturdy and Strong It Loads in Low Coal**

This coal loader is so designed and proportioned as to require 6 in. less headroom than other machines of the same type. Thus it cannot only work in a lower measure but can navigate passages through which the others could not travel.

## Self-Oiled Flexible Coupling Should Last Many Years

On Dec. 1 Smith & Serrell, of Newark, N. J., will place on the market a line of improved Francke flexible couplings intended especially for motor, turbine and engine drives. These couplings will be manufactured in 21 regular sizes and will be known as the "bushed pin type." Their ratings will range from ⅔ hp. per 100 r.p.m., with a maximum of 4,000 r.p.m., up to 3,850 hp. per 100 r.p.m., with a maximum of 490 r.p.m., and for shafts from ¾ in. to 13 in. in diameter.

As may be seen in the accompanying drawing, this new coupling retains the good features of its predecessor, known as the "heavy pattern type," and embodies several new ones of its own. Thus the end movement is easier and of greater amplitude. The power transmitting qualities are greater, as are also the bores. The new coupling also should have a longer life at all speeds. Steel flanges have been used on the small and intermediate sizes.



**Half-Section of Coupling**

The distinctive feature of this coupling which chiefly distinguishes it from all others is the renewable bronze or graphited bushings within which the flexible pin members are mounted and slide. These greatly reduce the friction of the pins and should last for years.

Graphited bronze bushings will be used in No. 850 size and larger, while bronze bushings will be employed in the smaller couplings. These bushings are removably locked to one flange and the steel-pin units are free to slide a full half inch within them. As compared with the older bushings the area of the contact surfaces is more than doubled and movement takes place between steel and bronze. Graphited bushings present self-lubricated surfaces that retain their lubricating qualities for many years.

This new coupling is capable of handling all accidental misinstallations such as the shaft being out of center or out of line and the like. The flexible pins cushion starting and load shocks and absorb vibrations. The coupling is noiseless and capable of operation in either direction. In case of excessive misalignment such a coupling acts as a safety device, obviating broken or scored shafts, bearing troubles and the like. However, if more than usual misalignment is anticipated, due to nonrigid foundations or from any other cause, two couplings in tandem with an intermediate shaft between them or a double, floating-ring type of coupling should be employed.

These new couplings are easily mounted, aligned, and fastened to the shafts they join without the aid of any special tools. They are of all-metal construction and embody no perishable material. There is no movement or wear on the shaft flanges to result in excessive renewal expense of these parts or of the complete coupling. The entire device is simple, rugged in construction and safe in operation.

## Makes Stronger Bearings

Greater strength has been put into the bearings produced by Standard Steel and Bearings, Inc., by a recent change. Balls were previously made of chrome alloy. Now they are all made of molybdenum steel. This was done not only to give the balls the toughness of armor plate but also because molybdenum is the only alloy that can be put into steel in an absolutely pure state. Molybdenum is obtainable in America in sufficient quantities for all steel purposes thus making the supply independent of foreign sources.

Street Bros. Machine Works of Chattanooga, Tenn., are now making an electric hoist in sizes above 30 hp. which have all of the refinements of the company's steam hoists with efficiency improved by an enclosed gear drive. Steel cut gears run in an oil bath and are totally inclosed in an oil-tight case.

## Trade Literature

**Small Tools.** Greenfield Tap & Die Corp., Greenfield, Mass. Catalog No. 49. Pp. 333; 5x7 in.; illustrated. Covers this company's line of small tools, including ground thread taps, spiral fluted staybolt taps, bolt and pipe threading machine. The book is well indexed for handy reference.

**Apex $CO_2$ Meter.** Uehling Instrument Co., Paterson, N. J. Bulletin 118. The principle of operation of this meter is described.

**American H. S. Fans.** American Blower Co., Detroit, Mich. Bulletin No. 6103. Pp. 31; 8½x11 in.; illustrated. Covers the various types of the American H. S. inlet fans which have been added to its line of Sirocco products. Tables of dimensions of the various types are given.

**G-E Mechanically Operated Flow Meters for Measuring Fluids and Gases.** General Electric Co., Schenectady, N. Y. Bulletin GEA-10. Pp. 43; 8x10½ in.; illustrated. Describes the flow nozzle and explains the operation of the meter.

**Belted Synchronous Motors.** Electric Machinery Mfg. Co., Minneapolis, Minn. Bulletin No. 812. Pp. 7; 8½x11 in.; illustrated. Describes synchronous motors of types designed for belted installations.

**The Link-Belt Co.,** Chicago, Ill., has issued an interesting book commemorating its fiftieth birthday. It is prefaced by notes on early conditions in some industries. The major part of the book, which consists of 47 pp., relates to the Link-Belt development.

**Carbon Circuit Breakers for Industrial Application.** Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. Circular 1705-A. Pp. 24; 8½x10½ in.; illustrated. Contains a description of this breaker, points out the functions of the breaker contacts and outlines its characteristics of effective shock absorption, adjustment and equalization of brush pressure.

## Publications Received

**Standard Methods of Chemical Analysis,** edited by Wilfred Scott, Sc.D., in collaboration with eminent specialists. D. Van Nostrand Co., 8 Warren St., New York City. Fourth edition. Vol. I has 748 pp. and Vol. II, 802 pp. Both volumes are well illustrated, and the price of the two is $12.

**Industrial Chemistry,** edited by Allen Rogers, in collaboration with other specialists. D. Van Nostrand Co., 8 Warren St., New York City. Fourth edition. Vol. I has 511 pp. and Vol. II, 756 pp. Both volumes are illustrated, and their price is $10.

**Financial Statistics of States,** 1923. Bureau of the Census Department of Commerce, Washington, D. C. Pp. 147; 6x9 in. illustrated. Price, 20c.

**Radio Telephone Modulation,** by Hugh A. Brown and Charles A. Keener. Engineering Experiment Station, University of Illinois, Urbana, Ill. Pp. 49; 6x9 in.; illustrated. Bulletin No. 148. Describes results of an experimental investigation of the intensity or degree of modulation obtained with representative types of radiophones.

**A 1925 Review of the Department of the Interior,** Hubert Work, Secretary. Pp. 39; 6x9 in.; illustrated.

**A. S. T. M. Tentative Standards, 1925.** American Society for Testing Materials, Philadelphia, Pa. Pp. 876; 6x9 in.; illustrated. Price, $7 in paper; in cloth, $8.

Bulletins 118 and 118-A, describing the **Apex $CO_2$ recorder and indicator,** are now ready for distribution by the Uehling Instrument Co., of Paterson, N. J. These instruments operate on the orifice principle and do not employ chemical solutions. The principle of operation is fully explained in the bulletins.

**An Investigation of the Efficiency and Durability of Spur Gears,** by C. W. Ham and J. W. Huckert. The Engineering Experiment Station, University of Illinois. Urbana, Ill. Bulletin No. 149. Pp. 94; 6 x 9 in.; illustrated. Price, 50c. Describes the Lewis gear-testing machine and gives results of efficiency and durability tests.

**1925 Year Book of the Merchants Association of New York.** Pp. 361; 7 x 19 in. Besides the list of members and various committees the activities of the association for the year ending April, 1925, are reviewed.

**Coal Analyses of Bituminous Coal Fields of Pennsylvania,** prepared by the U. S. Bureau of Mines. Pennsylvania Topographic and Geologic Survey, Harrisburg, Pa. Bulletin M-6, Part IV. Pp. 268; 6 x 9 in. In addition to analyses of Pennsylvania coals, the mines from which the samples were taken are given.

**Statistical Abstract of the United States,** 1924. Department of Commerce, Washington, D. C. 47th number. Price, $1 (paper covers). Pp. 824; 6x9 in.; tables.

**The Geology and Coal Resources of the Coal-Bearing Portion of Lee County, Virginia,** by Albert William Giles, with a chapter on "The Forests of Lee County, Virginia," by Harry Lee Baker, the former prepared in co-operation with the U. S. Geological Survey and the latter in co-operation with the Office of State Forester. Virginia Geological Survey, University of Virginia, Charlottesville, Va. Pp. 216; 7x10 in.; illustrated. Topographic and geologic maps.

**Trade Marks, Trade Names, Unfair Competition.** Richards & Geier, 277 Broadway, New York City. Third Edition. Pp. 46; 6x9 in. Covers trade marks in the United States and foreign countries; also schedule of charges.

**Patents—Law and Practice.** Richards & Geier, New York City. Third edition. Pp. 56; 6x9 in. Digest of United States law and practice and practice in foreign countries; schedules of charges in United States and on foreign patents.

**Second Annual Report of the Maryland Bureau of Mines,** under the supervision of the State Board of Labor and Statistics. Pp. 95; 6x9 in.; illustrated.

## What Does It Mean?

GOVERNOR PINCHOT, living up to predictions made last summer, has at last come forward with an eleven-point program for a settlement of the anthracite strike. From the public standpoint, the outstanding features of this program are the proposal to prohibit any increase in the price of coal, a long-term agreement and an immediate resumption of operations. That last proposal already has been invalidated by the declaration of Mr. Lewis that resumption will follow agreement—not the reopening of negotiations.

Mr. Lewis and his associates, agreeing to nothing, promising nothing except a readiness to discuss the Pinchot program with the operators, nevertheless emerge from the situation with the blessings of Gifford and more public approbation than has been their lot at any time since the head of the United Mine Workers so brusquely ended negotiations with the anthracite producers last August. The operators, who have been gathering favorable opinion to themselves because of the justice of their cause, are again entering a cloud of public disfavor. For this they have nobody to blame but themselves. Their refusal to attend the governor's Harrisburg party last Saturday, their plea for advance knowledge of what he would propose reveal anew a pitiful incapacity for gaging public sentiment.

As for the Pinchot program, the more it is examined the less it appears in the public interest. The first proposal is that there shall be no increase in price "by reason of this agreement." That provision contemplates, in essence, a concerted maintenance of prices which is clearly illegal. Moreover, it is a denial of the demand that the cost of anthracite be lowered to a point enabling hard coal to compete with soft. In view of that denial, the later provision for a study "to recommend methods for increasing the efficiency and reducing the cost of operation of the mines" suggests no public participation in the benefits of such a procedure. As a matter of fact, the attitude of the miners has been that those benefits shall be wiped out by wage increases.

In the light of what has taken place in the bituminous regions, a long-term agreement with no machinery for modification is not in the interest of either the miner or the operator. Nor is the public served if the inflexible wage basis fixed prove uneconomic, since the cost of industrial losses must ultimately be absorbed by the public at large—indirectly, if not directly. That which the public most desires—an uninterrupted supply—is not guaranteed beyond the life of the new agreement. Another "study" is to be added to the wearisome bibliography on how to avoid strikes, but neither party is pledged to acceptance of the recommendations made.

The only possible public gain promised by the governor's activities was an immediate resumption of operations. Mr. Lewis has made it plain that that gain is not to be had. The other promises in the Pinchot program are too illusory to justify enthusiasm.

## Father of Parliaments

ON DECEMBER NINE the Coal Mining Institute of America holds its annual meeting. Organized in 1887, it has had a long and laudable career—not only in what it has done itself, but in the institutions to which it has served as a model. None that have patterned after it have had, of course, so long a life nor indeed so vigorous a one. Located as it is, the Coal Mining Institute of America has been able to draw members as the city in which it meets has been able to attract citizens. Pittsburgh is a convenient center for a live and flourishing institute.

Many have friends and past acquaintances in Pittsburgh, and the annual meeting accordingly serves for them as an "old home week" where many coal men who have not come in contact for years greet each other once more and exchange confidences.

The Pittsburgh coal men have gone east, west, north and south and some have wandered into foreign climes, but the Coal Mining Institute of America is their first love, even though they may have others, and whenever they have an opportunity they slip back to greet familiar faces and talk over old times and modern developments. At its sessions they are sure to find those who will welcome them after their travels and inform them as to the health and progress of their cronies.

Thoroughly practical the institute has always been. Yet of late years it has kept a higher standard than in years past. In earlier days the budding politician occasionally found a chance at the summer banquet to try out his oratory on the patient members, never being quite clear whether he was addressing the United Mine Workers of America or a technical society. But those days when we used to hear about Tubal Cain and King Solomon are gone. We eat our meat today with better talent, and we digest it with greater comfort.

No institute, not even the American Institute of Mining and Metallurgical Engineers, has a better record for 100 per cent attendance at committee meetings. No programs are prepared with more care. So long as this condition obtains the life and vigor of the Institute will be assured.

The thirty-ninth annual meeting assembles next Wednesday. Let no consideration prevent the attendance of any coal man living within reasonable distance.

## Setting the House in Order

HERBERT HOOVER in his annual report of the Department of Commerce for 1925 gives a glowing and yet truthful appraisal of the financial and economic condition of the United States, showing that the wealth and well-being of the average worker never stood any higher than today. The railroad improvement is mentioned as one of the main underlying stones of the present economic structure. And here, we cannot avoid alluding to bituminous coal; the low price throughout the year, too low all will admit, has been kept from rising to undue levels by the excellent service of the railroads.

Many of the inflations of coal prices in years past have been due to the inability of the roads to handle traffic. It has been said that the transportation units of this country should not be planned to meet the unreasoning demands of the public. That is true, but when the railroads come nearer to supplying the public need, the public ceases to become panicky and no longer orders goods for long periods in advance of needs or annoys and hampers the railroads by complaints about delayed shipments and losses. Exits at theaters are made large for use in case of panic, but when there are plenty of exits the panics do not occur. So when there are many railroad cars there will be less anxiety, and no duplication, triplication and other multiplications of orders.

Standardization and simplification, as Mr. Hoover says, have done much to reduce waste. In the industries which cater to the coal mines standardization is difficult and makes slow progress, but it should be more rapid than it is. Greater standardization of the product of coal mines would be of great assistance. Nevertheless, the advantage of the movement is less in coal mining than in other lines, so that such immense savings as are reported in other industries seem amazing. Some day when every one burns small sizes of coal, savings like these will have been effected. But the process is slow as it involves large quantities of new consumer equipment and is not determinable on an act of will as is the size of a paving brick or the thickness of a plank.

The nation owes Mr. Hoover a debt of gratitude for his continued efforts toward greater efficiency. We are all of us laboring hard at jobs that simplifications would shorten and make lighter. The many items of Mr. Hoover's report will furnish many suggestions to the industrial operator, be he in coal or in any other business.

## Bringing Tools to the Work

GREAT ECONOMY in operation is rarely possible where the tool has to be brought to the work rather than the work to the tool. This is why all forms of excavation or the turning over of the ground have not been as economical of effort as manufacturing. To move the heavy tool around cannot result in as much efficiency as is attained when a light material is brought to a heavy tool. This is why farming, excavation and mining have not duplicated the economies of manufacturing.

With machinery, production is cheaper despite increasing wages, but no such result has been possible where the tools have to be taken to the work. At the mines there are examples of great economies of operation. But here in every instance the material moves to the tool. If coal were carried on the backs of packers up a 300 ft. shaft a ton per man per day would be a good day's hoist, perhaps. But now one engineer can hoist with modern equipment 11,000 tons per day if the material hoisted is delivered to it. Similarly pumps receive their material and effect prodigious economies, but where machines have to run around to get a chance to do their work no economies like those attained by the manufacturer are possible, though such economies as are attained are certainly worth-while. Those who declare that they did well in the old mule and hand-pick days exaggerate the results attained under such conditions and forget that the mines were small and near the tipple, that hours were longer and men worked harder and even then did not perform as much. To return to those days would double or triple the cost of our coal.

## Safety the First Consideration

WHEN THE NATIONAL government was formed, few anticipated that it would undertake to instruct industry in technique. It found too much difficulty in raising money by taxes to do anything but maintain the courts, a small army, Congress and the administration. But as time wore on, the Federal government gradually became wealthy and found that it could interest itself in the technique of industry, first with regard to farming and then broadly through an extension of the Bureau of Standards. Later the Geological Survey formed a technological branch which dealt largely with technique of coal.

So far nothing had been done federally for safety. At length a number of distressing explosions caused Congress to urge that the technological branch of the Geological Survey undertake an inquiry into the technique of safety, a study more germane to the duties of government than the development of mining and manufacturing processes. Surely the safety of the worker is a primary public interest, a form of technique more consonant with the fundamental purposes of government than any other. The U. S. Bureau of Mines was formed out of the technological branch largely because the need for safety had become imperative.

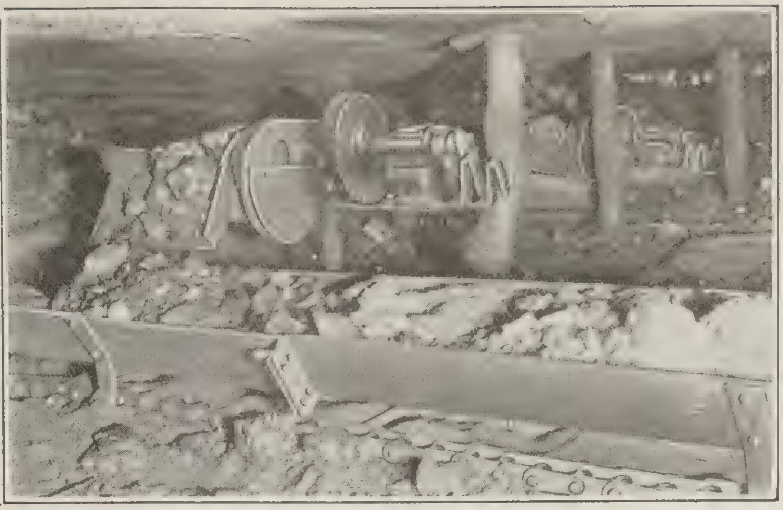
Had the Bureau taken up the matter in any half hearted, negligent or insufficient manner, its safety work might have been allowed to die without protest. But it succeeded so well that despite new hazards of increased depth, more gas, greater production, more machinery, more men in a single mine and larger and heavier transportation units, the growth in accidents not only did not increase but actually declined. For awhile safety drove out the greater part of the other activities of the Bureau. It became almost exclusively an institution for the study and promotion of safety. It branched out into mine rescue work. It trained men to perform the work of first aid and mine recovery.

The public has confidence in its work. It questions whether, if that work were left to each of the many states, it would be done as well. It notes with regret that state positions occasionally are held by men whose qualifications are political and not technical. It is confident that the Bureau of Mines is doing a more efficient work than the many mining states would do if left to themselves. So excellent has that work been that some states have sought co-operation of the Bureau in their inspectional activities and every coal operator who has tried to maintain good first-aid and mine-rescue teams has sought the Bureau's aid in keeping them in a high state of efficiency.

We hope that the Bureau's researches may some day be extended, but hold that not a dollar should be taken from safety work for the study of coal or metallurgical processes. It would be sad indeed if the Bureau should take as its motto the slogan, "Safety is not the first consideration." Such a decision would controvert the purposes for which that governmental activity was established.

# Conveyors Double Output per Man In Room Workings

## Raise Average to 16.23 Tons—Five-Man Units Can Cut, Drill, Shoot and Load Four Falls a Day and Do Dead Work Too



**By Alphonse F. Brosky**
Assistant Editor, *Coal Age*,
Pittsburgh, Pa.

IN TWO MINES under "Knickerbocker" management in Cambria County, central Pennsylvania, great concentration and speedy recovery are facilitated by conveyors in a room-and-pillar layout. These are the Telford mine of the Telford Coal Co. and the Jasahill mine of the Jasahill Coal Mining Co. By this means an appreciable saving in the production cost is effected. Once started, a room is driven to its limit and its complementary pillar brought back without delay.

The cycle—in and out again—has been completed in a minimum of 16 and a maximum of 21 consecutive shifts of 8 hr. each by five men who cut, drill, shoot and load the coal, besides handling draw slate, setting timbers and moving the conveyors. An average of three cuts from a room and as many as four from a pillar are taken each shift. And despite the fact that conditions are not the best, each miner has produced an average of 16.23 net tons per shift as against 7.28 tons under the old system. It would appear, furthermore, that the limit of productiveness has not even yet been reached.

Under the plan followed, each unit is composed of certain definite pieces of equipment and the complement of men necessary to operate them. Each crew is composed of five men. The equipment consists of: A main conveyor, 250 ft. long made up of 6-ft. sections. This is extended in driving a room and shortened in drawing a pillar. Two face conveyors, each 12 ft. long, discharge into the main conveyor (a complete description of these conveyors, known as the "Suppes," appeared in last week's issue of this magazine). One undercutting machine; a distributing or booster fan and canvas tubing; a 5-hp. hoist and the necessary wiring and lighting materials complete the outfit.

**Gravity Plane and Tipple at Jasahill Mine**

In accordance with the common practice where the coal bed lies above the railroad track in central Pennsylvania, at this mine loaded cars are utilized to pull the empties back up hill. As a result no power is consumed.

A strong conviction that long-face mining involves disadvantages outweighing its benefits has fortified the "Knickerbocker Mines" management in the belief that mechanization yields best results in a room-and-pillar layout. The simplicity of roof control in this system of mining as compared with that in longwall operations, especially when a room and pillar never attain a month's age, is sufficient justification for the retention of this system. The management holds that transportation is the most important factor limiting the productivity of any mining method. Light, sectional conveyors solve this problem in one system as well as in another.

The management believes it is not wise to concentrate mining areas without likewise condensing the phases of the mining cycle. Thus it maintains that in non-gaseous mines, at least, not only should every phase of a mining cycle be completed in one shift but that two, three or even four, such cycles should be consummated on each face in this same time interval. A

---

The headpiece accompanying this article shows two independently-driven lateral conveyors arranged in tandem to discharge into a main conveyor which extends from a room face to the entry. By the aid of these conveyors four men mine three 6-ft. cuts, 35 ft. long, from a room in 8 hr. This is 30-in. coal in the B seam, Jasahill mine.

The conveyors greatly assist in this work

FIG. 1

**Conveyors in Entry Work**

After the upper entry is advanced from *A* to *B* the equipment is moved to the lower passage which is driven 220 ft. from *C* to *D*. Thus the driving process is alternated between the two entries. While the lower entry is being mined rock is being taken to provide haulage height in the stretch from *A* to *B*. Room necks are developed along with the entry.

mining cycle, of course, comprises those operations (phases) which are required to complete one cut—undercutting. drilling, shooting, timbering and loading out. These considerations dictated a choice of the mechanized room-and-pillar system.

The general layout is as follows: Room headings, consisting of two entries 25 ft. wide on 80-ft. centers, are driven at 90 deg. off the mains leaving a 500-ft. room-and-pillar territory or panel between them. Rooms on 53-ft. centers are turned right and left or off both entries of a room heading. These rooms are 35 ft. wide and 250 ft. long, with 18-ft. pillars between them. Room headings will be approximately 2,750 ft. in length or long enough to accommodate 50 rooms upon either side. It is the intention to drive the room headings to their limits advancing and to mine the rooms and pillars retreating. It is highly desirable that the rooms and pillars on one entry of the cross heading be mined advancing while those on the other shall be mined retreating. In closed-lamp mines a triple-entry cross heading would be required where rooms are driven off both sides of a room heading. Another modification, that could be worked successfully, would be that of driving rooms off only one side of a two-entry heading, using only one conveyor unit to advance the headings to their limits and to mine the rooms and pillars on the retreat.

Inasmuch as entry driving precedes room-and-pillar work, it is well to consider development methods first, even though greater significance may attach to the mode of later recovery. In a sense, however, both plans are based on the same fundamental principles of quick recovery by the use of conveyors, wide places (where conditions will permit) and intensive mining accomplished by taking at least three cuts from one place in each shift.

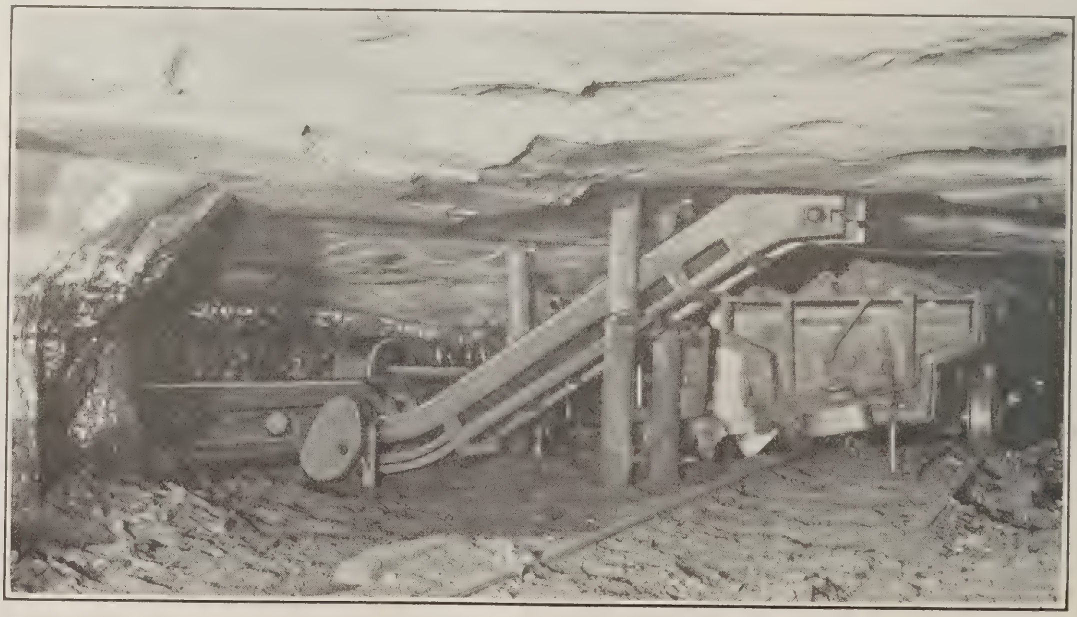
In Fig. 1 is indicated the plan by which an entry face is advanced at the rate of approximately 18 ft. per shift. The two entries of a room heading are extended by one mining unit, that also mines crosscuts through the chain pillar and develops the room necks.

The thickness of coal in both the Telford and Jasahill mines is not enough to provide sufficient height on the entries; consequently top or bottom, or both, must be taken. Brushing top and lifting bottom are operations performed entirely apart from that of mining coal from an entry. Having developed the upper entry from *A* to *B* (Fig. 1) the equipment is moved to the lower passage which is then advanced from *C* to *D*. The length of each step, that is, from *A* to *B* and from *C* to *D*, is about 220 ft. While the lower entry is being developed from *C* to *D*, rock is being taken down and the track extended in the upper entry from *A* to *B* as indicated by the herringbone hatching.

Sufficient rock is taken to provide from 5½ to 6 ft. of headroom over the haulway which is about 9 ft.

**Loading Boom on an Entry**

One man is stationed at the loading boom. He loads and spots mine cars in trips of 25. From 1½ ft. to 2 ft. of top or bottom must be taken on the entry for haulage purposes, indicating the thickness, or rather the thinness, of the seam. Roof is also brushed to give head room for the loading boom which must be elevated to clear the cars.



wide, leaving the remaining width or about 16 ft. of the entry for gob space. Furthermore, a pot hole is made at the mouth of each room neck to assure ample clearance above the loading boom of the conveyor during the room-and-pillar mining operation. Where the bed pitches, room headings as far as possible are for obvious reasons driven on the rise.

Entry driving, like room and pillar mining, is expedited by an adequate supply of mine cars. These are made up into trips of 25, into which the conveyor discharges a steady run of coal. In every second chain-pillar crosscut track is laid connecting the permanent track of the entry being advanced with a temporary track laid on the gob side of the parallel entry. A portable hoist, driven by a 5-hp. motor and remotely controlled from the loading station, is used to spot the cars composing a trip. The haulage arrangement is clearly shown in Fig. 1. As the direction of movement of the loaded cars during spotting is toward the dip, brakes must be set to hold them. The hoist moves the trip without these brakes being released.

The conveyor equipment can be used advantageously for handling rock. It has been thus applied in the driving of a stretch of the Fourth Main heading in the Telford mine, where bad roof was encountered under a stream. Here the entries, which customarily are driven 25 ft. wide have been narrowed down to 10 ft. At this point about 2 ft. of comparatively loose slate overlies the bed. This slate is temporarily propped up while the coal in each cut is being loaded out, after which it is taken down, loaded onto the conveyor and delivered to mine cars for outside disposal.

In panels *A*, *B* and *C* of Fig. 2 are indicated respectively the dimensions of rooms and pillars and the methods followed in driving the rooms and drawing the pillars. In panels *B* and *C* are shown also the arrangement of the conveyors and other equipment which provides quick recovery. As already explained room necks are turned and developed when the entries are driven. One mining unit advances a room heading to its limits; two such units, or one on either side, are utilized to mine the rooms and pillars in a full retreat.

### Arrangement of Conveyors in Room

Imagine for the moment panel *B* in the earliest stage or room driving. The room neck has already been mined 10 ft. wide and 30 ft. deep. At the mouth of this neck and extending over the entry track is placed the loading boom. Onto the rear end of the loading boom are added as many 6-ft. sections of main conveyor (about four) as are required to reach the face of the room neck. Here the widening-out operation commences. In three consecutive cuts, made in one shift, the room is flared out to its full width of 35 ft. In each shift thereafter at full room width the face is advanced a distance equivalent to the depth of three 6-ft. cuts until its limit, which is 250 ft. from the entry, is reached. As each breakthrough projection (on about 105-ft. centers) is reached the room pillar is pierced in three consecutive buttoff cuts. Mining operations here alternate between the room and the crosscut faces until the pillar is mined through. When the limit of the room is reached, the pillar is, of course, broken through at its extremity, completing the mining of the room proper.

The main conveyor is so laid as to maintain a clearance of about 7 ft. from the pillar and extends almost to the face. The roof over the gob area is supported by means of props on 5-ft. centers in lateral rows 6 ft. apart. The posts in the line flanking the main conveyor nearly touch it.

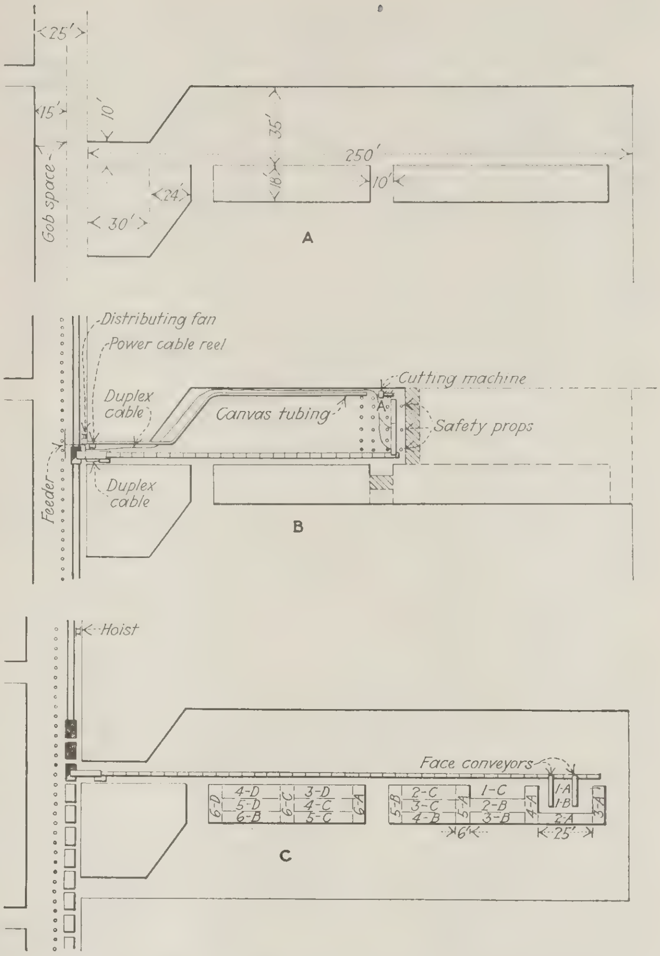


**Fig. 2—Room and Pillar Layouts**

Panel *A* simply gives the dimensions of rooms and pillars. Panel *B* shows the arrangement of equipment in an advancing room, and panel *C* indicates the method by which a pillar is drawn.

Within 2 or 3 ft. of the shot-down face are set in tandem the two 12-ft. face conveyors extending at 90 deg. to the main conveyor. The effective length of these two conveyors when in tandem is about 22 ft. so that they are within shoveling distance from the furthermost corner of the room. Where the roof shows weakness three safety props are set between the lateral conveyor and the face, within 18 in. of the coal. These timbers are set in position in the wake of the undercutter before the cut is shot. They interfere with loading to only a slight degree.

Four men out of the 5-man crew work at the face, the fifth man being stationed on the entry to load, trim and spot cars. As in entry driving, the spotting of cars in conjunction with room-and-pillar mining is accomplished by means of a 5-hp. hoist remotely controlled from the main control panel in the room neck. All electrical taps are made on a duplex cable. This is carried overhead across the entry from the feeder to a cable reel of the mining-machine type set up in the room neck. Branch circuits lead from this connection to the main conveyor drive and to a small fan which by the aid of canvas tubing delivers air to the face.

As the room face is advanced the cable is unwound from the reel. The end of this cable terminates at a junction box at the face. From this point electrical connections are made to the cutting machine, to the two independently driven transverse conveyors and to a flood lamp which illuminates the face.

A fuse on the mining machine and another on the main control panel in the room neck jointly guard all this equipment against overloads. The main conveyor may be stopped when desired by the men at the face as well as by the operator at its heading end. A snap switch on one of the face conveyors and a no-voltage release mounted on the main control panel prevent restarting. This feature is particularly valuable when the main conveyor is being used for transporting supplies and equipment from the entry to the face. It also serves as a safety precaution when work is being done on the conveyor unit.

The four face men work on their knees in low coal. They are stationed at equal intervals along the face. Shoveling is easy in that they are enabled to load the coal by a simple toss of the shovel; or the shovel, filled with coal, may be dragged back to the conveyor, lifted above the flare board and the coal allowed to slide off. In no case is it necessary to throw the coal far upward or outward from the shovel. The men go through no unnecessary motions and the exertion involved is less than a third that required to load into the ordinary mine car. This point is important as has been proven by actual practice, for a man in 1 hr. loads without tasking himself as much coal as he could load into a mine car in approximately 3 hr. of heavy exertion.

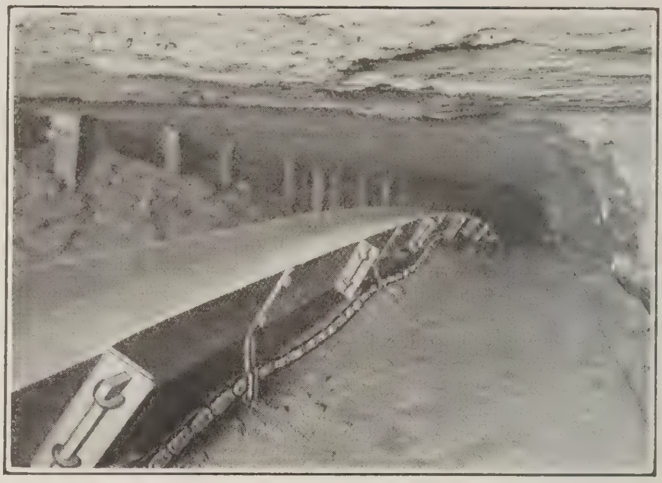
The four men load a width of face measuring about 24 ft. from the left-hand side of the room, leaving about 11 ft. on the right side. This last one-third is loaded out by two men while the other two move the undercutter from its position at *A* (panel *B*, Fig. 2) and start cutting from left to right. By the time the cutting machine reaches the center of the face the two shovelers have about cleaned up the previous cut. Having completed the clean-up the two shovelers become drillers and start on the left side to drill and charge the shot holes, in the wake of the cutting machine.

While cutting and drilling are in progress the fifth man on the entry loads onto the main conveyor the supplies and equipment necessary to extend it, reverses the direction of its travel and thus transports to the face the wherewithal for its extension along with timber and supplies. He then goes to the face where he joins his buddies in lengthening the conveyor.

The two transverse conveyors are moved to an advanced position within 2 ft. of the new face. Then while three men add a 6-ft. section to the main conveyor, the two others set a row of props behind the face conveyors. When these jobs have been completed the shots are wired and the men retire to safety on the entry. From this vantage point the charges are detonated by means of a battery. While the face is being cleared of gases and smoke by the distributing fan the men usually eat lunch. Thus one of the three cycles of room driving ordinarily completed in an 8-hr. shift is finished.

**Conveyor in a Room**

The stepped bottom is an indication of a local rise to the crest of a roll. Note that this conveyor accommodates itself to the rise and dip.



**Looking Out of a Room**

An average of three rolls are encountered in the driving of each room in the Jasahill mine, and the coal varies from 23 to 44 in. in thickness. The pronounced vertical bend in the conveyor in the background is noticeable. This room was started under the old system of mine car loading as indicated by the wall of rock taken from the bottom.

Turn now to panel *C* of Fig. 2, in which is illustrated the steps taken in drawing a pillar. Since the pillar is 18 ft. wide, three buttoff cuts, each 6 ft. in depth will pierce it. These buttoff cuts are made 25 ft. long, leaving a 6-ft. stump which is taken upon the completion of the adjoining buttoff place.

Three to four cuts are taken from a pillar in a shift. The sequence of working is indicated in Fig. 2 by a number-and-letter notation, the numbers indicating the places worked at one time and the letters the sequence of working. Thus during the first shift cuts 1-*A*, 1-*B* and 1-*C* are mined; during the second shift cuts 2-*A*, 2-*B* and 2-*C*; during the third shift cuts 3-*A*, 3-*B*, 3-*C* and 3-*D*, and so on. As shown, a room pillar can be completely drawn in six shifts. In many cases only four shifts have been required for robbing a pillar. The pillar is withdrawn only as far as the entry stump, which is left for later recovery with the chain pillar.

These abstract facts should be noted: The equipment composing a mining unit can be moved from a worked-out place to an adjacent room neck by five men in 12 hr. Toward the close of each shift it is customary to prepare at least one cut for loading at the beginning of the following shift. Each mining unit has its own cutting machine. All these arrangements lend themselves admirably to double-shifting.

Three units are installed in the Telford mine. Here the E seam being worked has an average thickness of 42 in. and is overlaid by 5 in. of draw slate which comes down or is pried loose and gobbed before the coal is loaded. Near the bottom of the bed is a 2-in. binder which is loaded with the coal. This breaks in big pieces which are easily detected and removed on the tipple. The coal is soft and friable.

One of the units here installed produced 17,371 net tons of coal in the first 214 consecutive shifts (including the time required to move the equipment from place to place), making an average of 81.17 tons per shift or 16.23 net tons per man-shift. In mining one room in which the draw slate was only 1½ in. thick this unit maintained an average production of 95.76 net tons per shift or 19.15 tons per man per shift. It mined another room and its complementary pillar, yielding 1,377.6 tons in sixteen 8-hr. shifts at an average rate of 17.2 net tons per man per shift.

### OTHER UNITS SHOW HIGH AVERAGES

The second unit installed in this mine in the first place worked, which was a 25-ft. entry, mined 1,072.96 tons in 18 shifts, an average of 11.92 net tons per man per shift. This same unit next mined a room at an average rate of 17.09 net tons per man per shift. In the third place mined by this unit, a room and a pillar, it produced an average of 16.01 net tons per man per shift.

The third unit installed in the Telford mine, with four men in the crew, mined 1,019.2 net tons from its first room in 16.8 shifts, or at an average rate of 15.16 tons per man per shift.

At the Jasahill mine the B seam varies in thickness from a maximum of 44 in. to a minimum of 23 in. Rolls, extending in any direction, are encountered at the average rate of three to a room. No draw slate occurs but a thin band of soft slate comes down with the coal.

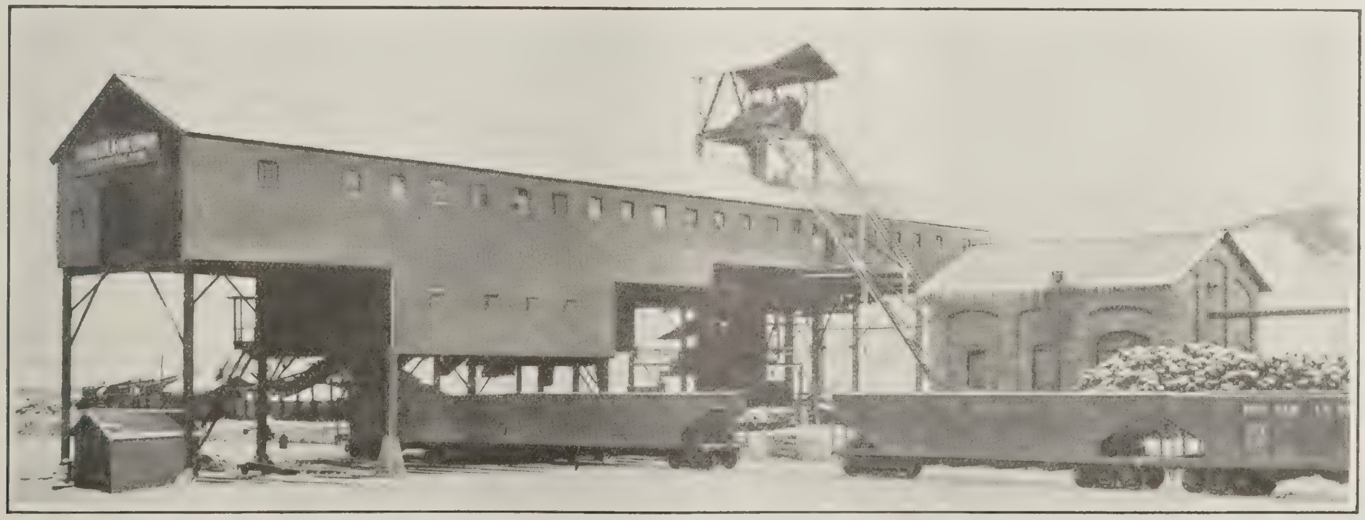
One unit is in operation in this mine. In the second place worked it produced from a room and pillar 1,258.9 net tons in 18.6 shifts at an average rate of 13.53 tons per man per shift. The average thickness of the bed in this room and pillar was 38 in.

Sixteen room-and-pillar places, five rooms without pillars and four entries (each of the latter being 220 ft. long) or 25 places in all, had been mined by the mechanical system up to Nov. 1. Neither the equipment nor the methods, therefore, is experimental.

## Top Works at Jerome Nos. 1 and 2 Mines, Hillman Coal & Coke Co. at Jerome, Somerset County, Pa.

**Jerome No. 1 Tipple Has Special Bin for Storing Crushed Refuse**

Jerome No. 1 is one of two operations at Jerome, Pa., of the Hillman Coal & Coke Co. The capacity of this tipple is 2,000 tons per day, the coal coming from the C-Prime seam. In the bin supported by steel legs, to the left of the tipple structure and to the right of the bridge, is stored crushed picking-table refuse which is burned in a steam plant. After passing through a crusher in the tipple the refuse is raised and dumped into the bin by a bucket elevator. Mine cars carry this fuel from the bin to the boiler plant which is located behind the tipple. The cross above the bin is not a part of the design of the structure. It is formed by a temporary horizontal working platform suspended from the bucket elevator housing.



**Tipple at Jerome No. 2, Where 2,000 Tons are Prepared Daily**

This tipple prepares about 2,000 tons of coal per day. The shaft is 225 ft. deep. During the winter of 1924 much of the coal from this plant and that from the Jerome No. 1 plant of like capacity went to Eastern and New England markets in competition with anthracite for domestic use. The coal comes from the low volatile, smokeless C-Prime seam of Central Pennsylvania. The slack coming from this plant ranges in sizes up to 2 in. and therefore makes excellent steam coal. Since this picture was taken this plant has been remodeled. Shaker screens, picking tables and loading booms were installed in the fall of 1924. Also the platform cages indicated by the headframe construction in this picture were replaced by self-dumping cages.

# Harmar Mine Raises Quality of Its Product By Overcutting in Impure Coal

## "Captive" Mine Shows Influence of Steel Industry—Ships by Either Land or Water—Problem of Housing in Limited Space Is Solved by Building Terraces

**By Alphonse F. Brosky**
Assistant Editor of *Coal Age,*
Pittsburgh, Pa.

WHERE DEER CREEK EMPTIES into the Allegheny River, less than nine miles northeast from the city limits of Pittsburgh, lies the Harmar mine of the Consumers Mining Co., a subsidiary of the Wheeling Steel Corp., one of western Pennsylvania's most outstanding coal properties. Several details both of surface design and operation differentiate this mine from the average run of the common herd. Thus, top cutting of the coal is practiced in preference to undercutting; the design of its houses differs radically from that usually adopted by most coal companies; the mine product is crushed before it leaves the tipple and can be shipped by either land or water. It is one of the most thoroughly rock-dusted mines in the country. The extremely interesting subject of rock-dusting practice will be treated in the Dec. 10 issue.

The shaft of this operation is 134 ft. deep, extending to the bottom of the Thick Freeport bed and hoisting is performed by means of 10-ton skips. Present production is at the rate of about 3,000 tons per day but the equipment has been designed for an ultimate capacity of 6,000 tons and this output will doubtless be attained eventually. The property comprises no less than 3,300 acres of coal which is enough to fully justify such large capacity.

This plant is all the more interesting because it is "captive," producing fuel solely for use in the parent company's byproduct coke works at Steubenville, Ohio. Being thus closely affiliated with the interests of another industry the operations at Harmar bear strong imprint of the influence which the steel works have exerted upon them. This is evidenced both in mining operations and in transportation. It is so marked in some respects as to render a number of the practices followed at Harmar distinctly different from those of neighboring operations.

The average thickness of the cover above the workings is about 450 ft.; the maximum about 650 ft. The roof directly over the coal is decidedly weak and has presented perhaps the most difficult problem encountered in mining the Thick Freeport bed, which in this mine, is about 86 in. thick and not all clean.

Entries are driven 12 ft. wide on 50-ft. centers. The main heading lies on a butt course and is composed of six entries protected by 200-ft. barriers upon either side. Cross headings, of four entries each, protected by 175-ft. barriers, are laid out at 2,490-ft. intervals. Double-entry room headings are turned every 400 ft., center to center, leaving 350-ft. strips of coal which

---

The headpiece accompanying this article is a general view of the upper works at Harmarville. The output of this mine can be shipped by either rail or river. An artificial harbor has been dredged to accommodate barges of 1,000 tons capacity into which are loaded 600 tons of coal which is all that the ordinary stage of the Allegheny River will accommodate. These boats are then floated down the Allegheny and Ohio rivers to the byproduct coking plant at Steubenville, Ohio.

are mined by 21-ft. rooms 300 ft. long pitched on 80-ft. centers.

The demand for steel from the plants of the parent organization is reflected in the demand for coal on the Harmar mine. And as the coal company is not engaged in any commercial business, when times have been dull in steel, the mine has worked intermittently or not at all. This fact, coupled with a bad roof condition, accounts for the adoption of a layout of wide rooms in a region where pillars are seldom twice as wide as the openings between them.

These pillars are being machine-mined by an 18 ft. wide buttoff place protected by a 10-ft. wing which is recovered partly by machine and partly by pick. A 6x10-ft. stump is left at either end of the wing, to be drawn later by pick, and the coal between the two stumps is machine-mined. Under better-than-average conditions the entire wing may be machine-cut.

Where two men work on a pillar, which is the common arrangement in this mine, each miner has a place to himself. Consequently, two places in one pillar are worked simultaneously. When the buttoff place nearest the inby end of the pillar is just through, the miner there employer starts back with the wing pillar while the other miner starts a second buttoff place outby of the first. A concentration system of three such places on a single pillar is being experimented with and may prove successful if the roof is not disturbed to any great degree, thereby causing undue pressure on the isolated pillar coal.

### SEVERAL LAYOUTS CONSIDERED

To avoid the danger just described a proposed layout of 22-ft. rooms on 60-ft. centers is now being considered. By this plan the pillar would be drawn by two men immediately following the completion of the room. Still another layout is being schemed, in an attempt to arrive at the best. This provides for 18-ft. rooms on 40-ft. centers. Concentration would be obtained by driving a set of six rooms simultaneously on an even front, working as many sets as are required to maintain a straight break line on an angle of 45 deg. to the headings. Pillars would be drawn, without interruption, following the completion of the rooms.

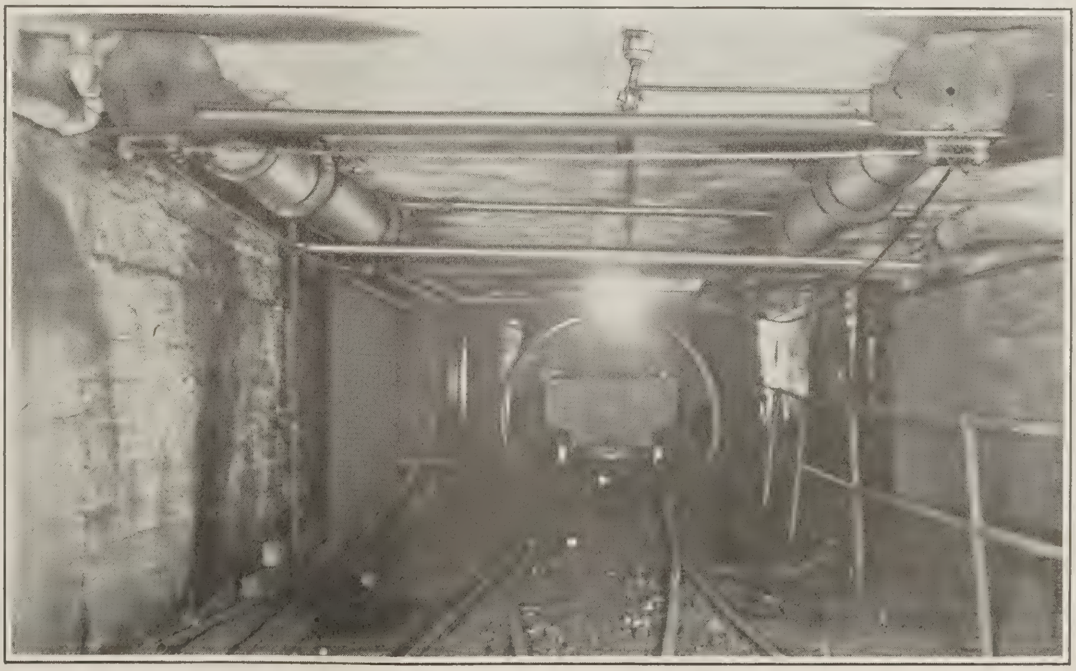
**Loaded Mine Cars at the Shaft Bottom**

Trip feeders have been eliminated from this mine by placing both loaded and empty storage tracks on a gravity grade. Thus the loaded tracks are on an inclination of 1¼ per cent. Heavy concrete piers protect the turnout points.

Within a section, mining would be pushed in a full retreat, which is the plan being applied to all the existing sections in order that splits of air may sweep the live workings first and then the goaf.

Twenty-five-pound rails are laid in rooms and butt entries. Coal is hauled in 3-ton steel cars to side tracks by storage-battery locomotives. Fifty-pound rails are laid in cross and main entries and from the gathering partings the coal is hauled in trips of 35 cars to the shaft bottom by two 13-ton locomotives. The maximum haul is about 1½ miles. If present plans materialize the main haulway will soon be laid with 60- or 70-lb. rails. This improvement will be in accord with the modern tendency toward heavier track.

Coal is discharged from the mine cars by a 2-car, air-operated rotary dump which has a continuous-performance capacity of 6 cars per minute. Inasmuch as the dumping cycle is only 6 sec. in duration, 14 sec. are available between dumps for changing cars, which is ample time. The gate equipment under the dump is capable of handling the contents of eight cars per minute. It thus will be seen that with the skip hoist-



**Rotary Dump**

Solid cars, turnover dumps and skip hoisting are all rather out of the ordinary in Pennsylvania mines. This dump is capable of discharging six three-ton cars of coal per minute with ease. It is actuated by compressed air, the operating cylinders being fastened to the roof instead of the floor as is generally the case. The dump is on a 1½ per cent grade so that the cars proceed across it by gravity without loss of time.

ing at the capacity rate of 6,000 tons per day the dumping and loading equipment would operate in a comparatively leisurely manner.

All of the shaft-bottom equipment is operated by compressed air under 80-lb. pressure. From the dump the coal is discharged into 4-ton weigh-baskets and from thence into a 38-ton bin. Fly gates, controlled by the dump operative, allow rock to be bypassed into a 30-ton rock bin. One such fly gate is arranged under each car so that one car of rock and one car of coal can be dumped simultaneously, as well as two cars of either rock or coal. Air gates on both bins regulate the feed from them to either of two measuring pockets. Manually-controlled air gates govern the passage of the coal from the measuring pockets into either of the 10-ton skips.

### Uncommon Shaft Bottom

In several respects the shaft bottom in the Harmar mine is out of the ordinary. The loaded and empty storage tracks are not parallel, as is often the case with cage-hoisting where end dump cars are shunted by a kickback from the loaded track through a shoofly to the empty storage track. A kickback layout is always a source of trouble, which might well be avoided where possible. This difficulty is surmounted in this mine by establishing the empty storage, as shown in Fig. 1, as a continuation of the loaded track but, of course, beyond the rotary dump.

Both tracks are double. Cars are fed to the rotary dump by gravity and taken away in the same manner. The loaded side has a storage capacity of 225 cars and is on a grade of 1¼ per cent. The empty side can hold 250 cars. It is on a grade of 1½ per cent within the limits of the runoff from the cage, and on a more gentle inclination from there on. In this way worries arising from inopportune breakdowns of car hauls or feeders are eliminated.

Where the mine output is dumped within the mine the danger, and detrimental effect of the coal dust upon the health and efficiency of the crew, is ever present unless some means is provided to abate this nuisance. This is accomplished in the Harmar mine by a rather ingenious control of the ventilating current in the vicinity of the main bottom.

The main intake is a concrete, man-and-supply slope which is 580 ft. long on a pitch of 14 deg. In this passage a brick curtain separates the manway from the supply compartment. The exhaust shaft is about 800 ft. from the main shaft, which is, of course, neutral, being neither a downcast nor an upcast.

At *E* in Fig. 1 is located an old shaft which formed a part of an earlier operation within the property and which is now being utilized as an auxiliary intake. The air drawn in through this shaft travels as indicated by arrows, to join that of the main intake. However, part of this air is separated from the main course, passes through crosscuts at *A* and *B* and returns along the empty track in a direction toward the hoisting shaft to a point *F*. Here a hole in the concrete entry wall, practically adjoining the shaft, connects with a crosscut which is on a secondary return to the fan shaft. In passing through this hole and crosscut in its return to the fan, this air carries with it any coal dust that may be raised in the dumping operation. A large part of this dust settles in the return between *F* and *D*. At the latter point a regulator is located.

This arrangement does not rob the mine of needed air as the fan is now producing only about 118,000 cu.ft. at a 2-in. water gage as against its rated capacity of 300,000 cu.ft. at a 3-in. water gage. With the fan working at capacity it would be possible to attain

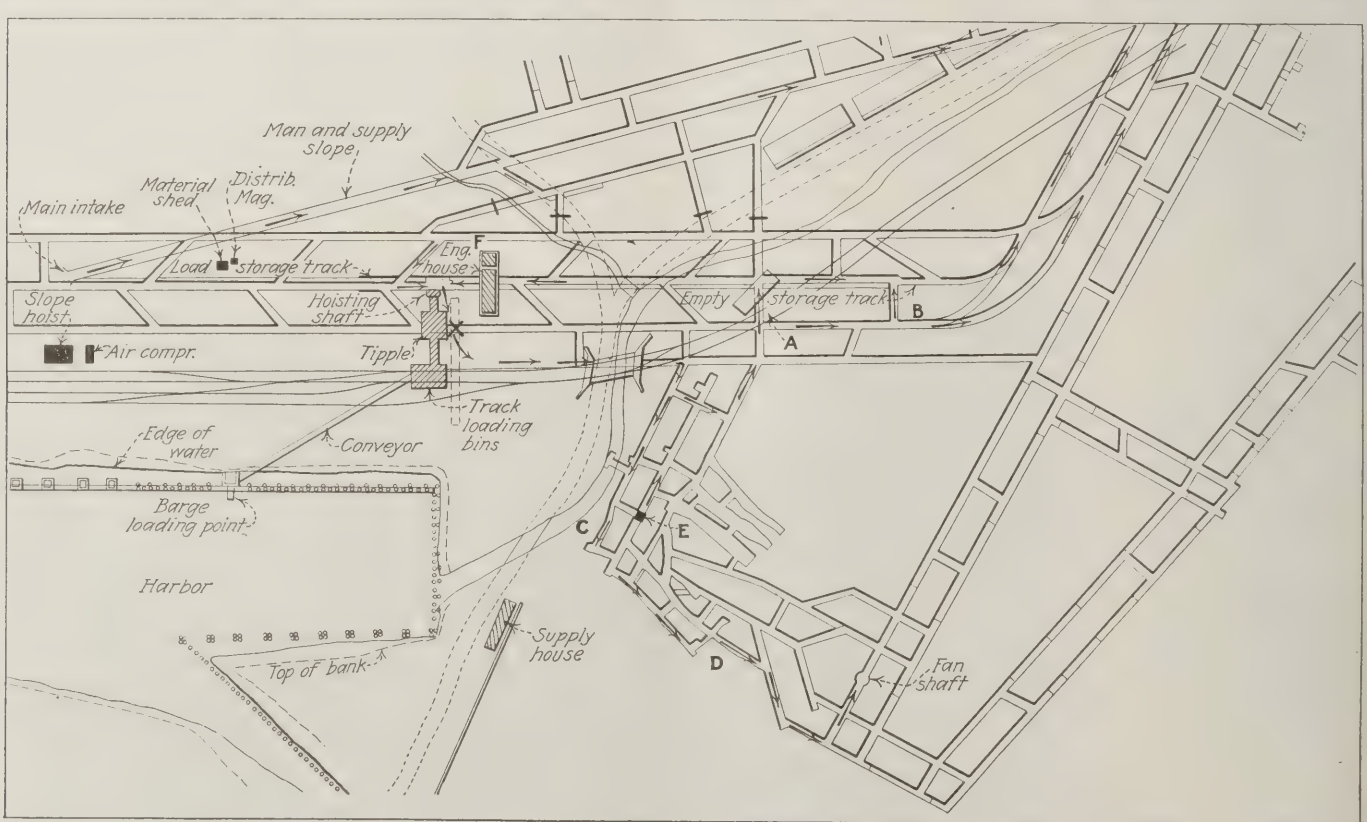


**Fig. 1—Layout of the Shaft Bottom at the Harmar Mine, Harmarville, Pa.**

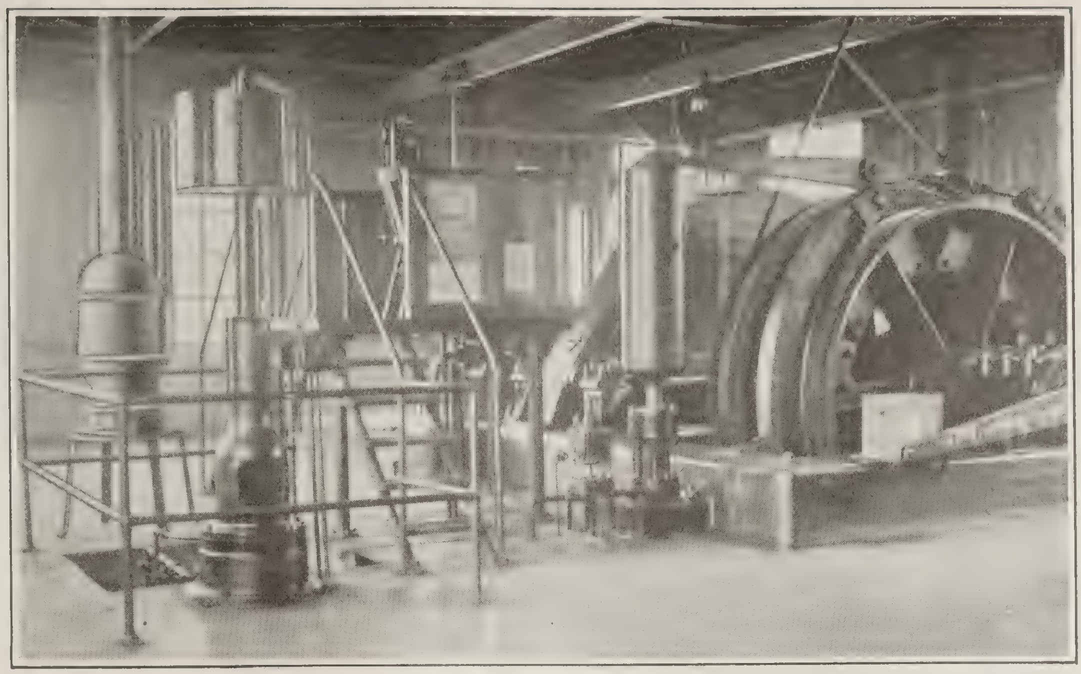
This is a gravity bottom and the track arrangement, accordingly, is very simple. A small quantity of intake air travels past the shaft foot, thus carrying away the dust raised by the rotary dump.

**Main Hoist**

With the present small output the rope speed is low, being only 590 ft. per minute. The hoist is driven by a 200 hp. motor backgeared to the drum at the ratio of 40 to 1. Thus equipped this machine is capable of handling the present load with ease. It is designed, however, for the application of a 600-hp. motor which eventually will be installed when the mine is brought up to its intended capacity of 6,000 tons per day. In the meantime the smaller motor draws far lighter loads from the line than would the heavier machine.



the same result by dividing the old shaft at *E* into two compartments, installing a small exhaust fan at the top of this shaft and erecting a stopping at *C*. The air taken in through the old shaft would then follow identically the same path as already described except that on its return to *C* it would be exhausted through the old shaft instead of through the main fan shaft, as is now the case.

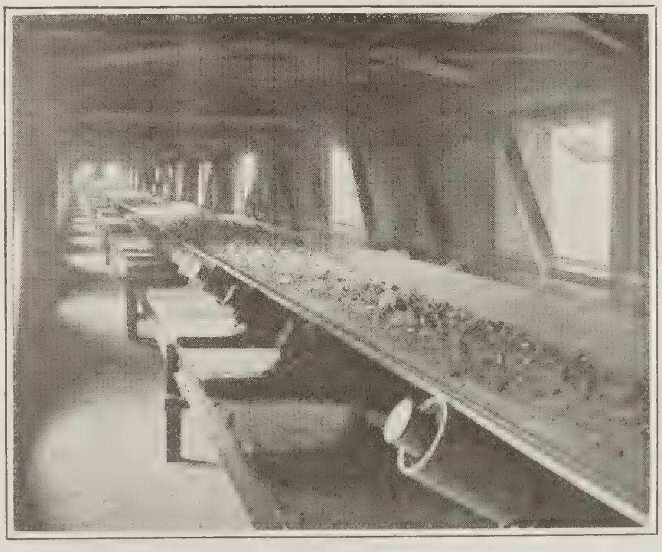
Apparently the management believes in slow-speed hoisting for it expects a maximum capacity of only 6,000 tons a day from the two 10-ton skips which have a lift of only 313 ft. between the bottom and top landings. Moreover, it does not believe in motoring the hoist to the ultimate requirements until such time as the mine is producing at capacity rate. It has installed on the hoist a motor which is smaller than that necessary to handle the capacity output of the plant. Its speed of hoisting is lower than the conservative speed at which the hoist eventually will operate.

The design of this hoist calls for a 600-hp. motor at a duty of 6,000 tons in 8 hr. Knowing that for several years at least the daily output would not much exceed 3,000 tons, a motor of only 200 hp. was installed. This machine gives a rope speed of only 540 ft. per minute by a 4 to 1 reduction to a counter shaft and a 10 to 1 reduction thence to the drum. The peak load on this hoisting equipment is about 150 amp. and the average load approximately 46 amp. The peak load with this arrangement is considerably less than it would be if a 600-hp. motor were used and a substantial economy in power is thereby effected. Simultaneously the slower speed effects a saving by lessening the wear and tear on the rope and other hoisting gear.

Coal is discharged from the skips into a 12-ton receiving hopper, whence it passes over bar screens which separate the slack from the lump. The slack may be delivered either direct to railroad cars or onto picking tables, under the lump. As a second alternative it may be delivered direct to a 1,000-ton bin. Run-of-mine either picked or unpicked can also be delivered direct to railroad cars or to the bin. The usual practice, however, is to run the picked lump through one of two 42x48-in. toothed-roll crushers, each having a capacity of 300 tons per hour, thus reducing it to sizes ranging from 2½ in. down. From the crushers this coal passes to the bin.

A steel apron feeder carries the coal from this bin to a 48-in. belt conveyor 64 ft. long which discharges either to chutes leading to railroad cars or onto a second apron feeder and thence to a second belt conveyor. The latter is 48 in. wide and 285 ft. long. It carries coal from the tipple to a barge loading station on an artificial harbor which connects with the Allegheny River at the mouth of Deer Creek. This harbor was formed by dredging out nearly 200,000 cu.yd. of material. It permits water transportation by 1,000-ton barges loaded with only 600 tons because of the low stage of the Allegheny above Pittsburgh. These boats are then towed from the mine to the byproduct coke plant at Steubenville on the Ohio River.

A vertical section from top to bottom of the Thick Freeport bed in the Harmar mine is roughly as follows: An 8-in. band of top coal, high in ash and sulphur; an upper bench of clean coal 2 ft. thick which



**River Coal Conveyor**

This conveyor which is 48 in. wide and 285 ft. long center to center, transports the coal from a 1,000-ton bin to a barge loading station on the artificial harbor. It has a capacity of 800 tons per hour at a comparatively slow speed.

**Mine Fan Operating on the Exhaust System**

This fan has a capacity of 300,000 cu.ft. of air at a 3-in. water gage. At present, however, it is so operated as to produce only 117,600 cu.ft. against a 2-in. water gage. The light on the line pole is a flicker signal indicating whether or not the fan is in operation.

is separated from the 3-ft. lower bench of clean coal by an 8- to 10-in. band of bone, and lastly there is an 8-in. band of bottom coal, likewise high in ash and sulphur. It should be remembered that this bed is under a weak roof.

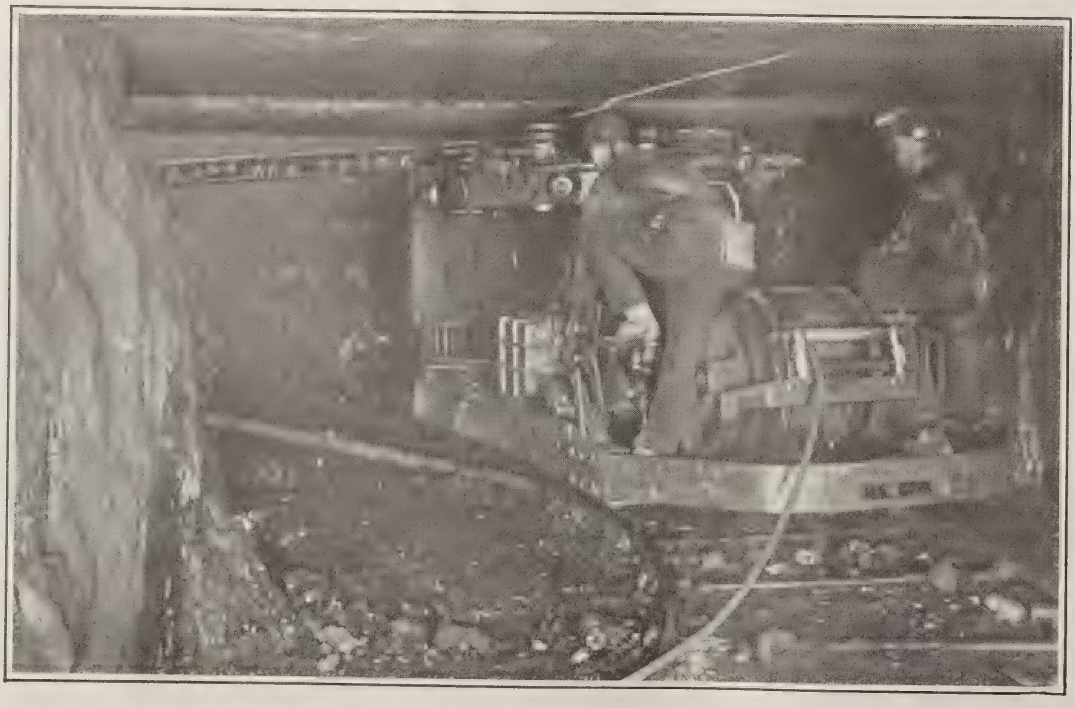
The metallurgical use to which this coal is put naturally demands a comparatively low ash and sulphur content in the raw fuel as delivered to the byproduct ovens. The bottom band of impure coal adds nothing to the output because it is not removed. The bone is separated from the coal at the face and on the picking tables. The top coal and roof material contributes largely to a high ash and sulphur content unless they are eliminated. This cannot be done well by hand seperation.

Until recently the general practice was to undercut the bed above the bottom coal. But this procedure was accompanied by the difficulties already reviewed and also entailed a heavy timbering cost. Thus in the majority of entries and rooms where the coal is undercut the roof is not self-supporting and requires the use of 4- and 6-in. I-beams, 12 ft. long, on 6- to 8-ft. centers. In addition the roof must be further supported by lagging, and cribbing wherever it has arched.

In an attempt to eliminate these difficulties a turret cutter was installed and gave such satisfactory results that a second and then a third machine of the same type were purchased. In fact, so well pleased is the company with the results obtained from these cutters that it intends to replace all of its other machines with them. But this, of course, will take time because the change will necessitate training runners, widening clearances, altering track arrangements and educating the miners to shooting top cuts instead of those made in the bottom.

The turret machine cuts below the top coal, thus avoiding its high ash and sulphur, and assisting in holding the roof. The cutterbar is 9 ft. long and makes a cut 9 ft. deep. The machine will sump in, cut across a 12-ft. entry face and sump out again in about 10 min.; it will similarly cut a room in about 15 min. The cutting is hard, especially as the upper bits come into constant contact with the high-sulphur top coal. The upper bits are changed after cutting one room or two entries and sometimes bits of all positions are changed with equal frequency. On an average, all bits are changed after cutting about 30 lin.ft. of kerf. Each of the three machines now installed cuts, on an average, 18 mixed places in 8 hr., which is a fair performance, all things considered.

In areas of solid coal, places that are top cut require no steel beams except under unusually wide spans of roof or where clay veins are encountered. It is difficult to keep the analysis of coal coming from places which are undercut, below 1.3 per cent sulphur and 9 per cent ash. Top cutting produces a coal that runs about 1 per cent sulphur and 7 per cent ash. The top coal in undercut places is loaded and paid for—an operation and cost which are avoided in the case of top cutting. A saving is realized also in the handling of slate and in the picking of refuse in the tipple.



**Top Cutting**

In this bed the coal next the roof is high in ash and sulphur. Cutting in the top stratum somewhat below the actual roof and thus leaving some coal in place, has rendered it possible to appreciably reduce both the ash and sulphur content of the mine product. But this is not the only advantage gained by top cutting. Where the coal is undercut heavy roof supports must be employed as the roof weathers readily and arches to great heights. This type of machine thus far has practically eliminated this difficulty. As rapidly as possible more machines of this kind will be added until the mine will be entirely equipped with them.

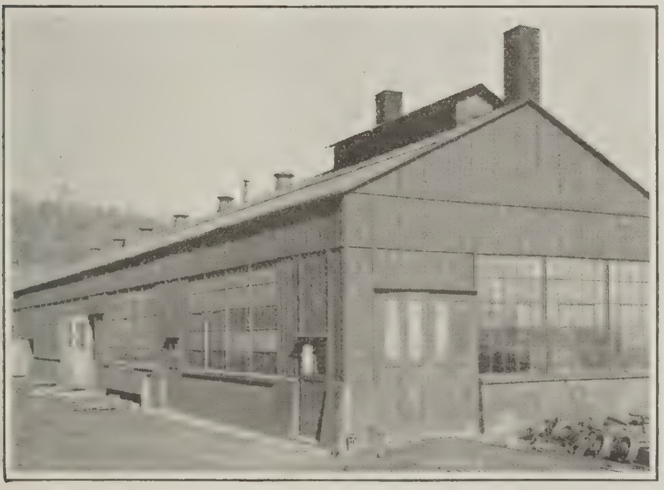
**Front View of a Terrace**

A few houses were on the property when the Consumers Mining Co., took it over. Construction of houses in rows such as here shown effected a substantial saving in end walls, which was reinvested in bath rooms and heating appliances. The wooden steps leading to the porches are soon to be replaced with concrete.

Altogether the topcutters are effecting appreciable economies.

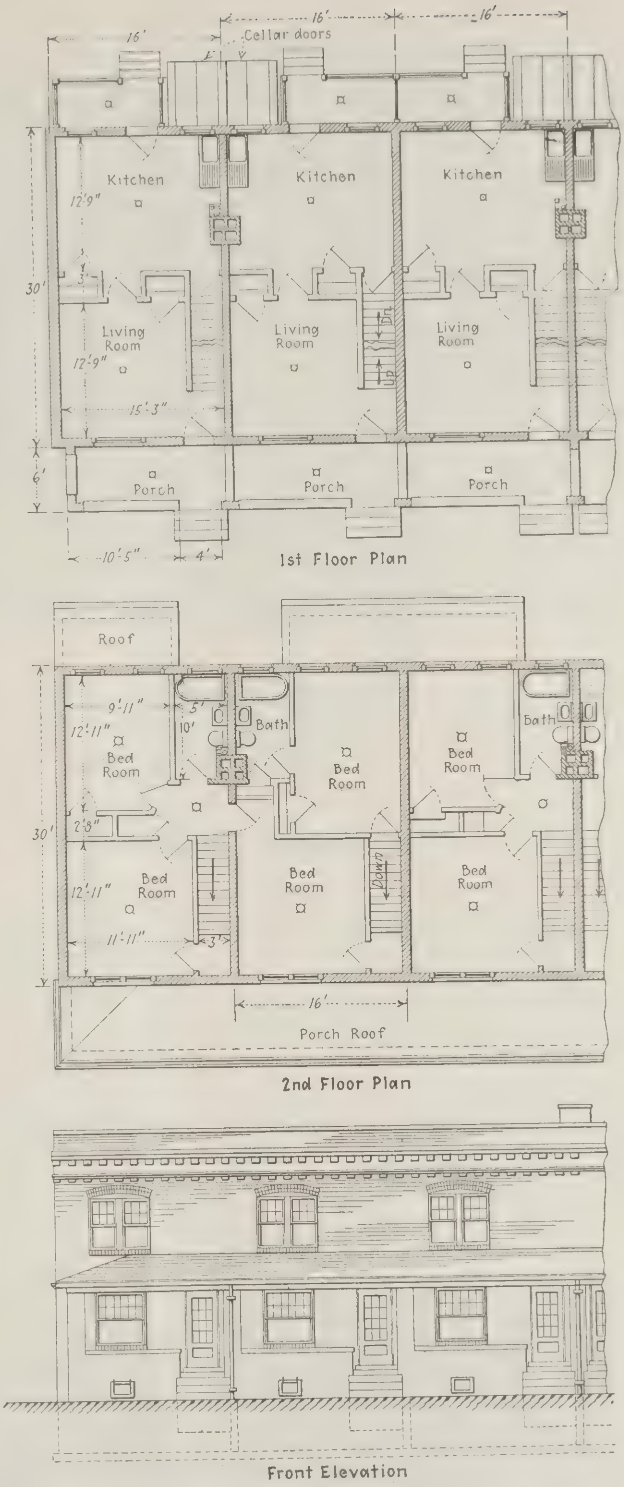
Housing at the Harmar mine is of an order at least equal to that of any coal company in the country. Dwellings are all substantially built; some of wood, some of brick and still others of stone. They are tapped to sewer lines which discharge into a sewerage disposal plant; they are provided with running water which is filtered and chlorinated before being delivered into the mains. All but 10 of the 134 dwellings at Harmarville have a bath room equipped with suitable fixtures; all are fitted with hot water heaters and all but 17 are supplied with hot air house furnaces.

This plant manifests clearly the potent influence that the steel industry has exerted upon its industrial housing. There are here 17 five-room bungalows, 16 brick rows or terraces in each of which is a combination of 3-, 4- and 5-room apartments, as illustrated in Fig. 2, which shows floor plans and a front elevation of a typical row. These 16 terraces contain 117 apartments. Fifty-three of these have four rooms, 32 have three rooms and 32 have five rooms. In addition to the above buildings there are five double stone houses.



**Portable Steel Shop Building**

Blacksmith, machine and electrical shops are all joined together and under one roof. Such buildings as this have the advantages of being light, easily erected and when worn out have a salvage value.



1st Floor Plan

2nd Floor Plan

Front Elevation

**Fig. 2—Floor Plans and Elevation of a Terrace**

Level ground is at a premium at Harmarville. Accordingly, rows of houses were built in place of the single dwellings ordinarily found at coal plants. Even with the housing facilities provided, many of the men prefer to live in nearby communities and travel to and from work by auto, trolley or train.

By no way other than that described could the men at this plant have been comfortably housed because level ground near the plant is limited in extent. Obviously, even the housing facilities provided are insufficient to the needs of all the workers of the Harmar mine. However, as the town is on a hard macadam road and is served by both a trolley and a railroad, a large number of the men prefer to make their homes in Parnassus and New Kensington, two neighboring fair-sized industrial and business communities.

Sewage is conveyed from the houses through 4-in. tap lines discharging into a 10-in. main. Partly by

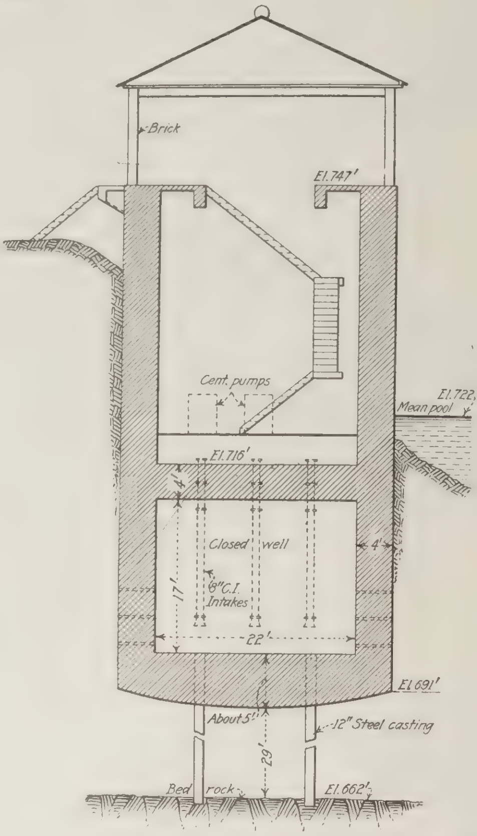


**Fig. 3—Cross-Section Through Pump House**

Water for the town of Harmarville is filtered naturally. A large circular well curbed with heavy concrete was sunk to a depth well below the bed of the river and the water allowed to reach it by flowing through the glacial drift of the river shore. Even though thus purified by the natural filtration this water is chlorinated before it is delivered to the house mains.

gravity and partly by pumping it is emptied into a syphon chamber and passes thence into an Imhoff tank where it is digested. The effluent is chlorinated before its final discharge into the Allegheny River.

Earlier in this article it was stated that Harmarville water is filtered. This is, indeed, the case, but the filtering is not artificial. Water from the under flow of the Allegheny River is forced hydrostatically by its own pressure through a considerable thickness of sand and gravel in the stream bed into an airtight well chamber lying below the bottom of the river. From this well it is pumped to a storage tank elevated well above the town.

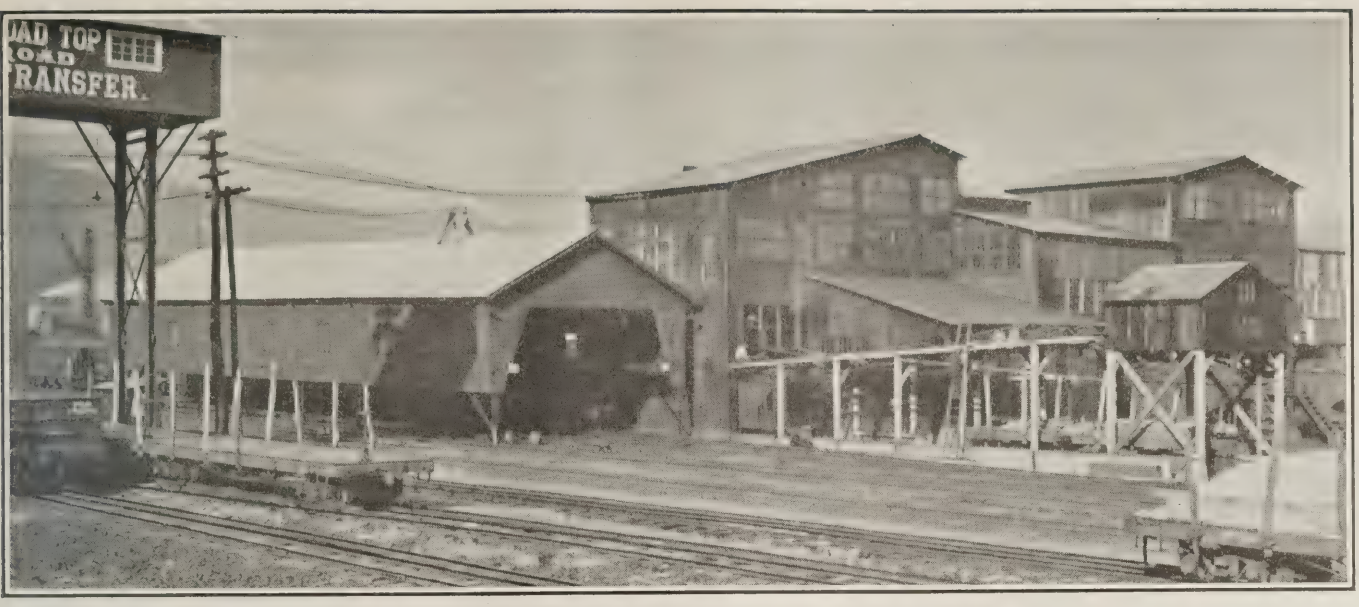
Fig. 3 is a section through this water plant. A circular well 22 ft. in inside diameter with reinforced concrete walls 4 ft. thick extends from the high water stage of the river to a point 31 ft. below its mean stage and 19 ft. below the river bottom at the point where the plant is built.

The circular concrete shell was sunk by the open-caisson method. The walls were built thick and heavily reinforced in order that they might withstand the heavy ice flows which occur on the river in the early spring. At the bottom of the shell is a concrete floor 5 ft. thick which was laid under water. In it are twelve 12x12-in. seepage holes. Also projecting through this bottom and extending downward to bed rock, are four 12-in. steel casings perforated by ⅛-in. holes on ½-in. centers and extending throughout a 10-ft. zone measured from the bed rock upward. The bottom of the well wall also is provided with 30 weep holes. These various openings are the means by which pure water from the underflow of the river finds its way into the well chamber which is air-sealed by a roof wall 4 ft. thick and placed 17 ft. above the bottom of the well. Projecting through this roof wall are three cast-iron intakes, two of which are each connected to a centrifugal pump, having a capacity of 500 gal. per minute against a 120-ft. head. The third intake is plugged at present as the water requirements of the plant and town are not sufficient to warrant the installation of a third pump.

As the water leaves the centrifugal pumps it is chlorinated and then passes through a 10-in. line to a 60,000-gal. reservoir tank. Whenever the pumps are in operation the water is delivered direct to the house lines, only the surplus going into the tank. In case of fire, water may be delivered under heavy pressure direct from the pumps to the fire plugs.

**Harmar Officials**

Kneeling, from left to right: R. E. Shaw, master mechanic, Frank M. Correl, safety inspector; Sam Yates, fire boss; James Sampson, fire boss; Frank Smith, motor boss. Standing, from left to right: Joe Middlemas, machine boss; J. F. Adamson, superintendent; A. A. Schneider, mine foreman; D. R. Snyder, fire boss; Cliff Barton, weigh master; D. Foster, assistant mine foreman; H. Couch, assistant mine foreman; Walter Giesy, mining engineer; John Beatie, assistant mine foreman; Earl Adamson, fire boss, and Charles Sneddon, coal inspector.



# Sand Flotation Process Enters Bituminous Field

## Cleaning Method Well Known in Anthracite Is Now Used in Central Plant Serving Three Broad Top Mines—Cuts Ash Content to Uniform Percentage

**By Alphonse F. Brosky**
Assistant Editor, *Coal Age*,
Pittsburgh, Pa.

A MECHANICAL bituminous coal-cleaning plant which in point of technique employed differs from all others in the bituminous coal industry is that located at Mt. Union, Pa., approximately midway between Pittsburgh and Philadelphia, on the main line of the Pennsylvania R.R. Here for the first time the Chance sand flotation process of preparation is applied to bituminous coal on a commercial scale.

This plant serves a double purpose. First, it transfers coal from the narrow-gage equipment of the East Broad Top Railroad & Coal Co., to standard-gage equipment of the Pennsylvania line; and second, it provides preparation facilities.

Coal here treated comes from the East Broad Top mines of the Rockhill Coal & Iron Co., at Robertsdale, Pa. These are in the Fulton bed, which averages 4 ft. of coal, divided into two benches by a parting of slate and fire clay. The thickness of this parting varies from about 2 in. to 5 ft. The bottom bench of coal is fairly uniform being about 1½ ft. thick, while the top bench varies from 2½ to 3 ft. in thickness.

The Broad Top deposit lies within the folded area of the Appalachian field, and consequently the Fulton bed is wavy. Its contour resembles that of a strip of corrugated sheeting. The rolls within the bed, which pitch heavily, preclude the economical use of undercutters and coal, accordingly, is shot off the solid. This breaks the parting into more or less small pieces.

In 1914 a plant combining transfer facilities and hand-picking equipment (screens, picking tables and loading booms) was erected at Mt. Union by the East Broad Top Railroad & Coal Co. to handle coal originating on its lines. The Rockhill Coal & Iron Co. took advantage of these facilities and shipped the following hand-picked sizes: Run of mine, lump (over 4½ in.), furnace (through 4½ in. and over 2 in.), range (through 2 in. and over 1 in.), and stoker (through 1 in.). Such has been the past practice of the coal company. The capacity of the plant on this basis was 250 tons per hour.

Coal from the Fulton bed is one of the lowest volatile bituminous fuels in the country, possessing a high heat value. As such it is a coal enjoying a specialty market and wide distribution in its sized form as domestic fuel.

Because of the physical characteristics of the Fulton bed and the practice of shooting from the solid, a large quantity of the binder contained in the bed is broken into pieces too small for efficient cleaning underground. Twenty-six men on the picking tables in the old plant were unable to control the ash content sufficiently to meet the requirements of the market served. When uniformly free of impurities this coal is ideally suited to the ceramic industry where kilns must be drawn through a heat of predetermined maximum intensity in a given time. It is suited also to domestic use, as well as to power plants and railroads that operate within the limits of cities which have stringent ordinances directed against smoke.

The potentialities of these specialty markets made a uniform product essential. Wide fluctuations in the ash

---

Of the three structures shown in the headpiece the largest is the coal-cleaning and transfer plant of the Rockhill Coal & Iron Co. This is operated by the East Broad Top Railroad & Coal Co. in connection with its coal transfer station. The long, narrow building adjacent to the washery houses the dump pits which, together with coal-handling equipment, facilitate the transfer of coal from cars on narrow-gage railroad track to cars on standard-gage tracks. The three-rail combination tracks are easily seen. Arrangements are such that of the coal coming from the mines of the Rockhill Coal & Iron Co. in the Broad Top field, that which is under 4½ in. is conveyed into the washery for treatment. The transfer plant has been remodeled from an old structure to which a cone house has been annexed. Of course much new equipment has been installed.

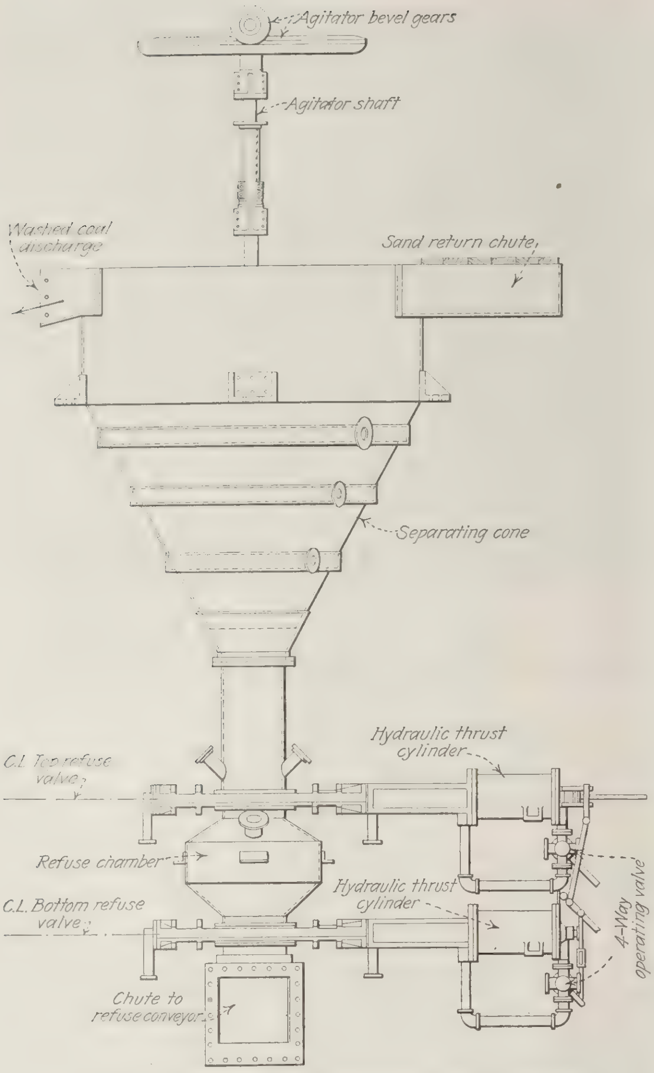


**Fig. 1.—Chance Sand Flotation Coal Cleaner**

and sulphur content of coal shipped from the mines resulted at the least provocation as, for instance, from an increase of output. Hand-picking methods were futile in any attempt to keep the ash content fixed.

Coupled with this fact, it was found necessary to increase the capacity of the Mount Union plant in order to accommodate increased tonnage produced at the mines. The results which were obtained by hand picking indicated that if a larger tonnage were to be handled and hand-picking methods continued not only would the force of pickers have to be augmented but additional picking facilities would have to be installed.

It was decided, as a result, to investigate various methods of cleaning coal with the idea of installing a suitable mechanical process which would eliminate the human element in preparation.

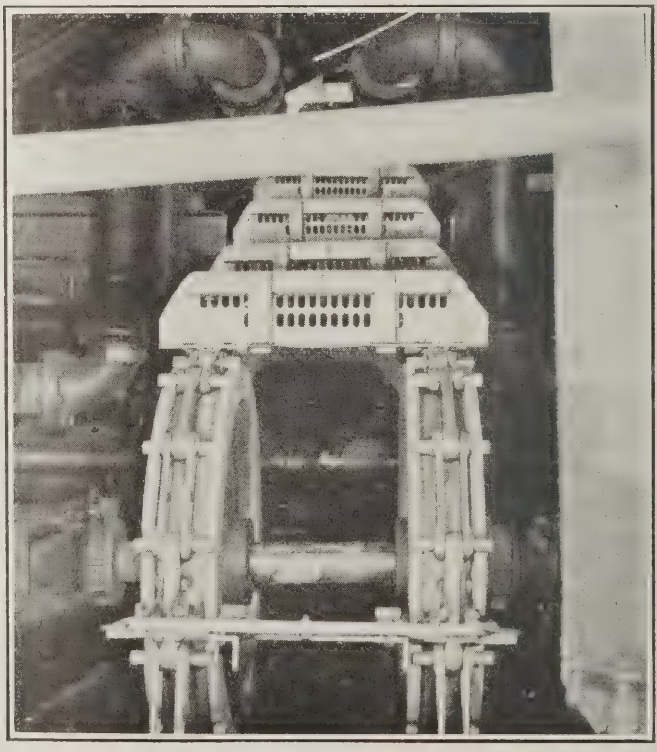
An investigation of various methods, including the sand flotation process, was carried on over a period of a year. At first the company hesitated to adopt any wet process because of the moisture which would thus be added to the coal. However, a study of shipments over a period of years disclosed the fact that an average of four days elapsed before the coal reached its destination, during which time it would likely encounter rain or snow. The mere fact that consumers had not complained of moisture derived from this source dispersed the fear of the relatively small quantity of moisture that would be added by the cleaning process.

The use of sand was not viewed with favor until after thorough tests had been completed. These showed that the sand can be completely removed from the washed coal without difficulty.

The coal to be treated was subjected to complete screen and float-and-sink tests with liquids of specific gravities ranging from 1.4 to 1.6 on all materials passing through a 1-in. square opening. It was a foregone conclusion that the coal passing through 4½-in. and over 1-in. openings would have to be cleaned, because of the concentration of impurities within this range of sizes. The results of these tests showed that the cleaning of coal smaller than ⅜ in. was unnecessary, its ash content was not high and remarkably uniform. The proportion of this small size amounts to 15 per cent of the total product.

It was decided to continue preparation of the material passing over 4½-in. openings by hand-picking methods. Its quantity, however, represents only 18 per cent of the total product. The final outcome of the investigation, therefore, was the adoption of the Chance process for the cleaning of the sizes between the 4½-in. and ⅜-in. products.

Sand flotation as here applied is "the floating of coal on a fluid mass of sand and water" through which slate and other refuse readily sinks. This flotation of the coal and sinking of the refuse is accomplished in the cone separator shown in the illustrations. The top of the separator is a cylindrical collar, in which the coal is separated from the refuse. From its bottom a cone tapers downward and conducts the refuse to a central discharge point at its extremity. This leads to a large diameter pipe known as the classifier column where the sand is separated from the refuse. Below this pipe is a trap chamber for the refuse which may be closed or opened at the top or bottom, as required, by means of two valves. Below this trap is a chute which conducts the refuse to a scraper conveyor.



**Refuse Conveyor**

This conveyor drags the refuse drawn from the cones to the refuse desanding shakers. It is driven from the main countershaft in the cone house.

FIG. 2

**Flow Sheet**

This drawing is to indicate the course of the coal from the time the sizes to be washed are screened out, until they are fed through the two units of the sand flotation cleaner, and delivered at the discharge points. The refuse and coal are both desanded thoroughly before loading so that the actual leakage of sand out of the cleaning cycle is negligible.

Within the collar, extending from a level slightly below a discharge lip to practically the bottom of the cone, is a fluid mass composed of sand and water of a specific gravity greater than that of the coal but less than that of the slate, which are separated. This fluid mass is sustained by water entering the cone through the classifier column. The flow of this water through the classifier controls the specific gravity of the fluid mass—the less water the greater the specific gravity of the mixture. On entering the cone this water loses its velocity and is spread horizontally in "sheet-like layers" which percolate gently upward through the sand, displacing that water which is above it.

A spindle shaft extends into the separator coinciding with its main axis. To it are attached horizontally projecting paddles. These revolve within the fluid mass and, together with opposing injections of water from three peripheral manifolds, serve to agitate the cone's contents. These two agitating agencies serve to counteract each other and result in a tendency toward whirlpools, eddies and boiling. The fluid mass, however, literally revolves with the arms as a solid and in so doing serves to transport the floating coal through an angle of nearly 360 deg. from the point of feed to that of discharge. Overlying the fluid mass is a layer of clear water.

Over the top of this fluid mass is introduced and drawn off a gentle flow of sand and water, in a closed circuit from and to a sand sump. The separation of slate from coal takes place on the surface of the fluid mass as the coal floats in a circular path through nearly 360 deg. At the discharge lip the coal runs out of the separator in company with the overflow of sand and water. The sand and water are sieved from the washed coal on shaking screens adjoining the separator.

The Mt. Union plant as it stands today is a remodeled installation, with the addition of a building that houses the coal washing equipment. Incidentally no changes were made in the track layout under the tipple. As now arranged, this plant has a capacity of 500 tons of coal per hour, of which 335 tons per hour is washed. A flow sheet of the equipment appears in Fig. 2.

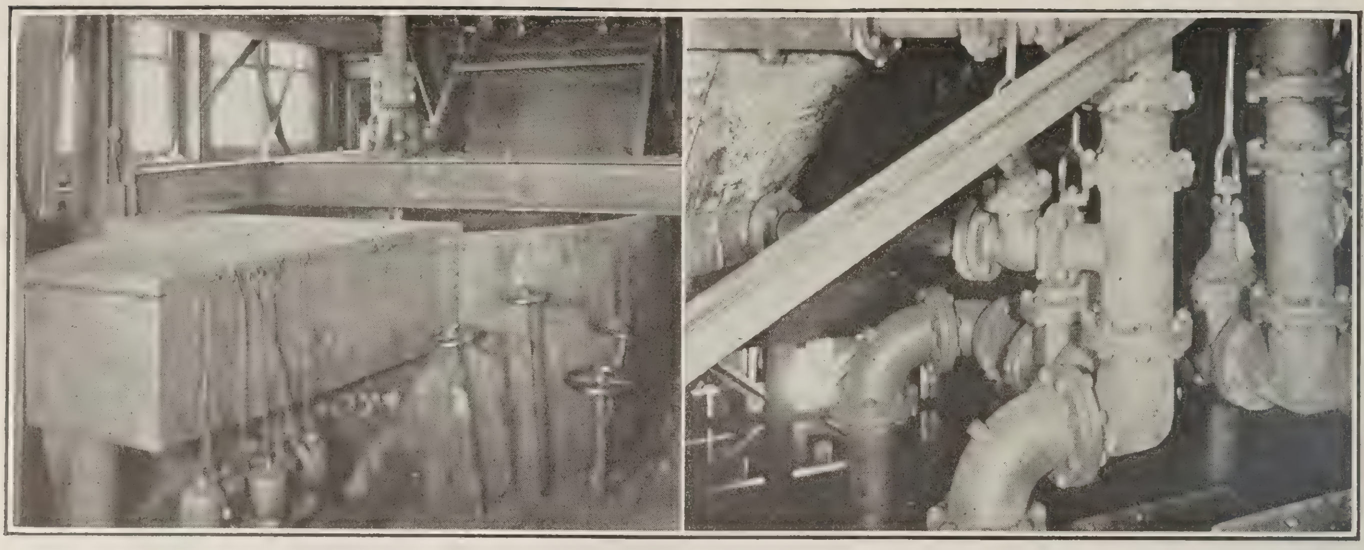
Coal is delivered to this plant from the mines 30 miles away in narrow-gage hopper cars, each of 35 net tons capacity. It is dumped into two 100-ton pits, from which it is drawn by automatic feeders discharging onto two inclined apron conveyors. These deliver the coal at a common point onto a shaking screen 6 ft. wide. This shaker is dressed with four plates 3 ft. long having 4½-in. round openings. The coal passing over these openings is discharged as large lump onto a combination picking-table and loading boom where it is picked by three men before being loaded into standard-gage railroad cars. By adding plates with 10-in. round openings to the lower end of the shaker, two sizes of lump (under and over 10 in.) can be prepared. A second or small lump picking-table and loading boom is provided for this purpose but has not been used as yet.

That coal which passes through the screen openings on the shaker is carried by a 42-in. scraper conveyor to a battery of four double-decked vibrating screens. The upper deck of each vibrator is dressed with wire screen having 1-in. openings over an effective area 4 ft. wide and 10 ft. long. The lower deck which has the same effective screen area as the upper one is dressed with wire screen with ½-in. openings. As these screens are installed on a 34-deg. slope, the effective size of their openings is about ⅞x1 in. in the upper and ⅜x½ in. in the lower deck. Each deck is composed of two 4x5-ft. screens in tandem.

Each vibrator is independently driven by a 3-hp., 1,200 r.p.m. motor through eccentrics of which there are two for each screen. These eccentrics are of small throw and are driven at high speed. Each vibrator has a capacity of 100 tons of feed per hour. Their capacity per square foot of screen area is believed to be greater than that of any other screen of the same general type yet developed.

These vibrators divide the coal into three distinct products: (1) coal over 1-in., (2) that under 1-in. but over ½-in. and (3) that under ½-in. The No. 1 product, as a combination of furnace (under 4½-in. and over 2-in.) and range (under 2-in. and over 1-in.) is washed in No. 1 cone of the cleaner. The No. 2 product is known as sized stoker and is washed in No. 2 cone. The No. 3 product in dry form is reunited with the sized stoker coal after the latter leaves the dewatering and desanding screens.

This division into three sizes is not made to facilitate a better separation of refuse from coal in the cones. No. 1 and No. 2 products are of approximately the same quantities and are equivalent to the capacity of the



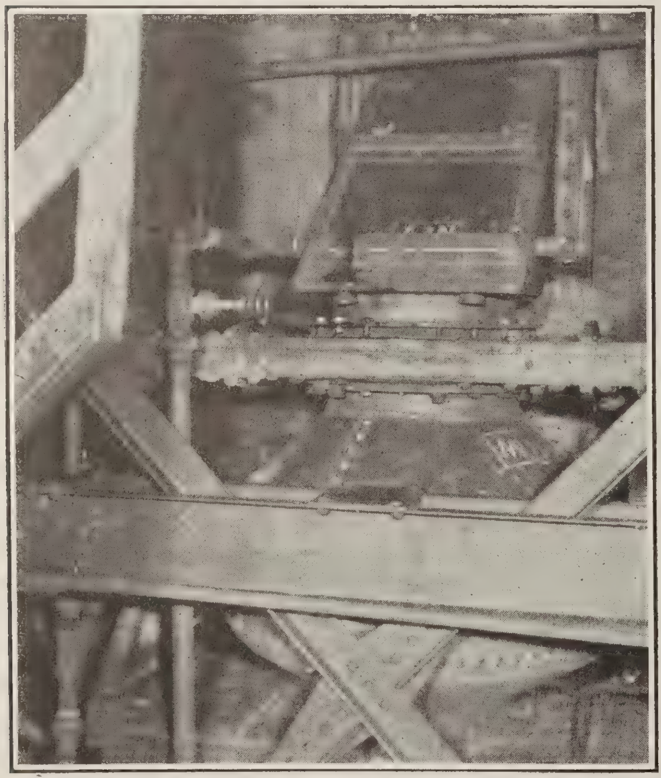
**Furnace and Range Cone Separator and Fresh Water Lines and Valves to Both Cones**

The coal is fed from the guard screen which is shown above and at the far side of the separator in the illustration on the left. Sand and water are pumped through the stand pipe in the foreground and flow gently into the separator. The refuse sinks through the fluid mass on which floats the coal. The objects hanging from the sand-and-water intake are specific gravity measuring weights. The valve stems are carried to this floor to facilitate the work of the cone operator in controlling the flow of water through the classifier column and the manifolds.

Taps from the water lines shown on the right lead to the manifolds and the classifier column. Practically all water circulated is reclaimed and reused.

separate cones. The No. 3 product, as stated above, does not require preparation. As a matter of fact, the No. 1 and No. 2 products could be cleaned in the same cone as well as separately if the capacity of the plant were less.

The No. 1 product (furnace and range), passing over the upper deck of the vibrators, is delivered onto a drag conveyor and carried to a 30-in. belt which transports in to a vibrator, of the same type as those already described but having only one deck. This is dressed with ¾-in. square-opening screens. It serves only as a guard screen for the removal of fines which in dry form are joined with the washed stoker size. The coal passing over this vibrator is fed to the No. 1 cone where the refuse is removed from it.



**Refuse Chamber and Chute**

Refuse sinks to the bottom of the separator where it is discharged at intervals of about 4 min.

On leaving this cone, the coal together with a certain quantity of sand and water flows onto the upper deck of a double-decked, balanced shaker 5 ft. wide and 4 ft. long. By this machine the fluid mixture of sand and water is sieved from the coal. The upper deck is dressed with two plates about 3 ft. long each, provided with 3/32-in. perforations. These two plates in the upper deck hang over in the clear of the lower deck and through their openings is sieved, almost all of the sand and water which accompanies the coal onto the upper deck. What little sand clings to the coal is removed by sprays of fresh water, located at intervals along the remaining length of the shaker. Adjoining the two plates of small openings on the upper deck are five plates, each about 3 ft. long, provided with 2-in. openings which separate the range from the furnace coal. The latter is then delivered over a loading boom into a railroad car.

The range coal on the lower deck passes over six plates, each about 3 ft. long, provided with 3/32-in. openings and is washed by sprays of water, removing the few particles of sand which yet adhere to it. The range coal is then delivered to the railroad car by a 30-in. belt loading boom. So much for the No. 1 coal.

The No. 2 product upon leaving the lower deck of the main battery of vibrators is discharged onto a drag conveyor which delivers it to a 30-in. belt, which carries it to a single deck vibrating screen, 4 ft. wide and 10 ft. long providéd with ½-in. square openings, which removes the fines from the sized stoker coal. The fines are reunited with the material from which it is separatd after the latter is washed. From the vibrator the sized stoker coal is fed to the No. 2 cone where its refuse is separated from it.

On leaving the No. 2 cone this coal is desanded and dewatered in the same manner as is the product from the No. 1 machine. The shaker over which this size is passed is dressed on the upper deck with two plates having 3/32-in. openings. These overhang and clear the bottom deck, and through their openings the coal is almost completely desanded. Adjoining these two plates on the upper deck are five plates perforated with $\frac{3}{16}$-in. openings under which on the lower deck are six plates with $\frac{3}{32}$-in. openings. These together with jets of fresh water serve to remove what little sand is not sieved through the two small-opening plates on the upper deck.

The product on the upper deck of this screen is blended with that on the lower deck and both, together with the dry steam sizes are fed to one compartment of a 60-in., two-compartment apron conveyor. The other compartment is used only when run-of-mine coal is made and carries blended furnace and range coal. The stoker coal is discharged from this conveyor into a small hopper and thence into a railroad car.

Run of mine is made by closing the gates over the furnace and range loading booms on the No. 1 shakers, allowing these sizes to be discharged into the 60-in., two-compartment conveyor carrying the stoker coal. All three products are thus transported to a 48-in. belt conveyor. This leads to a chute where the smaller sizes join the lump in the formation of run of mine which is loaded into a railroad car on the lump track.

The refuse sinking through the fluid mass within the cone separator is trapped in the refuse chamber, from which it is drawn off at about 4-min. intervals. The discharge of refuse from this chamber is controlled by hydraulically operated interlocking valves. The refuse is discharged into a scraper conveyor which carries it to a refuse shaker. Here it is washed to recover the sand, and discharged to a refuse car by which it is transported to and dumped upon a rock bank.

The sand and water which is sieved through the shakers is sluiced to the sand sump, which acts as a large settling tank. The settled sand is returned to the cones by means of sand pumps of the centrifugal type. The relatively clear water overflowing around the rim of the sump is collected in a small reservoir which acts as a sump for the fresh water agitation pump. This pump is a 10-in., double suction, centrifugal of the volute type, with a capacity of 2,500 g.p.m. against an average head of 60 ft. The discharge from this pump supplies fresh water to the classifier columns and manifolds of both cones, and also for the sprays over the desanding and sizing shakers.

Make-up water is drawn from a reservoir located about a quarter of a mile from the plant by a 300-gal. centrifugal pump. This machine discharges approximately 200 g.p.m. through a 5-in. line into the top of the sand sump.

Sand and water are returned to the top of the cones from this sump by two sand pumps, each of 1,050 g.p.m. capacity at 33-ft. maximum head when handling 10 per cent sand by volume. The parts of these machines which are exposed to wear are made of manganese steel.

The plant was put into operation on Oct. 1 of this year and, because of the short length of time between the start of operations and the date of this article, analyses are neither complete nor sufficiently detailed to warrant publication. However, it has been proven beyond doubt that the process as applied to the cleaning of bituminous coal produces a product of uniform quality so far as ash and sulphur content is concerned. The average of analyses received to date shows a fluctuation in ash of approximately $\frac{3}{4}$ per cent and a variation in sulphur of 0.2 per cent.

Coupled with this result analyses so far made show marked reductions in ash and sulphur content of the product, as compared to that shipped when hand picking methods were employed,—the largest reductions being of course shown in the furnace and range sizes.

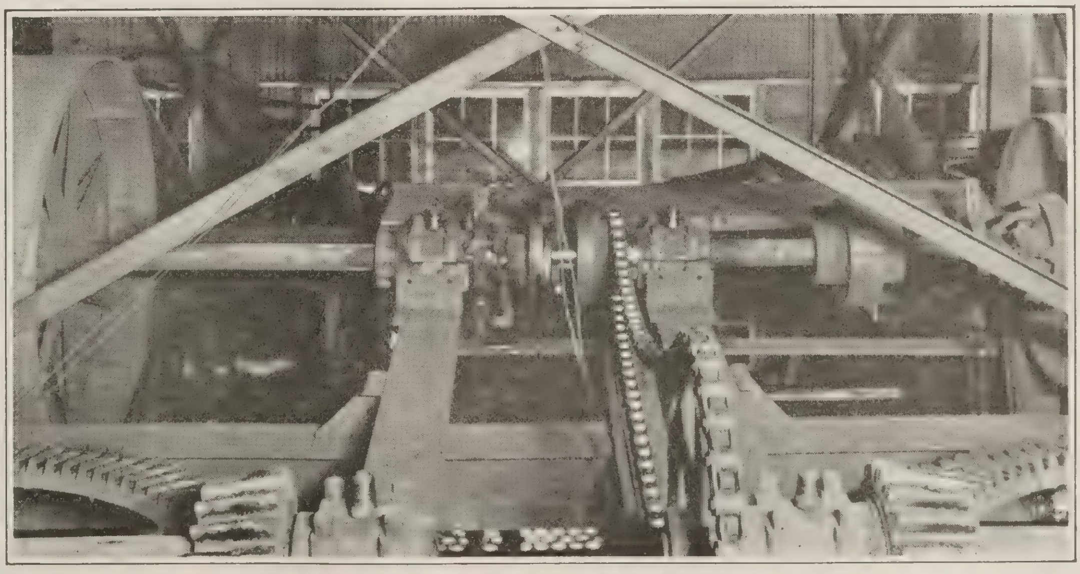
The aim underlying this installation, was naturally, the elimination of refuse from the shipped product, but this elimination is not desired at a sacrifice of good fuel. In other words, no attempt is being made to obtain a product having ash and sulphur contents equivalent to the inherent ash and sulphur of the pure coal. This would mean the elimination of fuel of relatively high value from the shipped product. The important thing which is being accomplished at this plant is the production of a coal of relatively low ash and low sulphur content, that is of uniform quality.

The best impression of the process is gained from watching the discharge of refuse from the plant. The rejected material is largely slate, mixed with bone to which adheres a little pure coal. A generous sprinkling of pyritic sulphur within the mass is readily distinguished. On the other hand, an inspection of the washed coal in the railroad cars discloses uniformly sized products which to the naked eye at least are free from mechanically included impurities. No sand was observed clinging to the washed coal.

The plant was designed and erected by the Coal Cleaning & Equipment Co. in collaboration with H. M. Chance & Co., both of Philadelphia, Pa.

**Main Drive**

It was the aim in the design of this plant to simplify the layout by locating motors at points which provided secure anchorage, and to drive combinations of units from common countershafts. This not only has simplified the drives but also has eliminated many nests of reduction gears in dangerous and inaccessible places. Also it has avoided the installing of motors and reducing gears on stilted moorings. A 75-hp. motor drives by a belt this countershaft.



# Better and Cheaper Coal Mined with Greater Safety Discussed by West Virginia Institute

LESS EXPENSIVE and more complete coal extraction, preparation that will lower impurities, shooting that will increase the quantity of large coal, flame-proof motors that will aid in eliminating gas and dust explosions and projected concrete that will keep roofs from continued scaling, formed part of a symposium on means to improve West Virginia practice in mining at the winter meeting of the West Virginia Coal Mining Institute held at Morgantown, W. Va., Nov. 24. To complete the symposium a visit was made Nov. 25 to Nemacolin, Pa., to see a mine where some of the important means suggested had been put in practice, or had been replaced by some other means tending to the same end.

R. M. Lambie, the president, occupied the chair and the meeting set down to work without the usual formalities of a welcome from the mayor and the Chamber of Commerce, the first paper being one on the "Smokeless Coals of West Virginia," by David B. Reger, of the West Virginia Geological Survey. Mr. Reger described first the semi-anthracite coals found in the Pocono series in the counties of Berkeley and Morgan, which lie in a sort of lip which projects from the northeastern portion of the state. The counties which are little known interpose themselves between Maryland and Virginia. Apparently the field which is only about 13 miles long and a mile or two wide has coal so folded and overturned and so impure as to be of little value, the impurity, however, not being part of the coal but mixed with it. The coal itself has only 6.47 per cent of ash.

Mr. Reger defined smokeless coal as that having a fuel ratio of from 5 to 2.5. Coal of this character can be found in fairly continuous, but no wholly unbroken, line from the state of Maryland in the northeast down to McDowell and Mercer counties in the south of the state and following a line about southwest. In Randolph, Pocahontas and Greenbrier counties smokeless coals certainly exist but have not yet been studied. The explored fields, consequently, divide themselves into two, one occurring in Mineral, Grant and Tucker counties in the northwest and the other in Fayette, Raleigh, Wyoming, McDowell, Sumner and Mercer counties in the South. The first field has a little over two billion tons available and the lower field in excess of eleven billion tons. The fields have been barely scratched, despite the extensive operations that have been carried on for years.

Frank Haas, consulting engineer, Consolidation Coal Co., remarked that his investigations established the fact that not all the coal in Fayette County, despite the common belief, was smokeless or semi-bituminous. Mr. Reger agreed with that statement provided it was assumed that the true dividing line could be set empirically at a fuel ratio of 2½. Still he asserted that the greater part of Fayette County could lay claim to having smokeless coals in accord with that definition. He agreed with Mr. Haas that smokelessness accorded not so much with the geological horizon as with the geographical location, though along the edge of the smokeless field certain seams were less smokeless than their geographical location would lead one to suppose.

Thomas Fraser, who is assistant professor of the mining engineering department of West Virginia University, then read a paper on the "Preparation of Commercial Coals" showing the sizes adopted for anthracite and for the southern Illinois coals, the operators in the latter district having been compelled to adopt a careful classification of coal into sizes in order to meet

---

The headpiece shows some of the participants in the West Virginia Coal Mining Institute's session grouped on the steps of the Post Office at Morgantown, W. Va.

the competition of hard coal. He said that some such sizing would have to be provided for West Virginia coals if the coal of that state was to be put into successful competition with the product of the anthracite-producing districts. He showed by tables how coal of different sizes in the same mine had different ash and sulphur percentages and exhibited different degrees of beneficiation as a result of cleaning by washing and pneumatic-table preparation.

Josiah Keeley, general manager, Cabin Creek Consolidated Coal & Coke Co., Kayford, W. Va., questioned why it was that the seam sample showed an analysis always better than the purchasers found when the coal was received. Mr. Haas said that the personal equation had something to do with it. The man who sampled the coal in the mine, was always disposed to believe that the miner would reject certain obvious layers of the bone and slate. When the coal was mined, however, much of this impurity was loaded; in fact, it could not be wholly eliminated no matter what care was taken.

J. J. Forbes, of the U. S. Bureau of Mines, declared that in taking a face sample a $\frac{3}{8}$-in. binder would be rejected in the hope that the miner would throw it in the gob. That is not what happens. The miner almost invariably, when he gets it on his shovel, deposits it in the car. In France, a central bureau makes tests of the coal at the tipple, and the coal of the mine is accepted or rejected on the railroad tracks at the mine before the coal has been transported to the market.

Frank Haas then read a paper on the "Flameproof Motor as a Safety Measure." He said the first flameproof motor constructed in this country was manufactured in 1903, but such motors had been used in Europe at an earlier date. He urged on the members that it was impossible to keep a mine which generated gas in quantity entirely free from the hazard of an excess gas percentage. A stopping might be broken down by a fall of rock or a big area in a panel where the pillars were beginning to be drawn might cave a little, causing the gas to collect above the fall and to be precipitated violently into the working area when the first major fall occurred. Therein lay the need for flameproof motors.

R. L. Kingsland, chief of the power and mechanical division, Consolidation Coal Co., said that no more power was being used now per ton of coal mined with storage-battery power than when the current was conducted by wires from the power house to the face. Furthermore the demand was now far better distributed. True, there were power losses of 20 to 25 per cent in the operation of the battery, but there were losses greater still in the feed lines of a wire-equipped mine. It was not uncommon to have 175 volts at the generator and only 100 volts at the undercutter or locomotive. Furthermore, with a storage battery there was a constant voltage. Mr. Haas declared that it was not necessary to have twice as many locomotives with storage-battery operation as with other forms of mechanical haulage. The locomotives and also the cutting machines should have battery capacities to supply them the full day. The company's locomotives haul 1,000 tons in 8-hr., but the batteries are changed after a 4-hr. run.

B. C. Collier read a paper on the advantages of projected concrete, emphasizing the necessity for repairing breaks promptly and of using a sufficient thickness of the concrete to assure permanence. Less than that might do good for a while, but later it would be found that the concrete had cracked and would begin to fall. He gave many instances where the gunite had served to prevent falls, an dto act as a protection in case of mine fires.

Mr. Stockdale, general manager, Bottom Creek Coal & Coke Co., said that a long sidetrack 35 ft. wide at the Bottom Creek mine had been covered with projected concrete eighteen months ago. Though the roof was bad and before being coated looked quite unsafe it has stayed up without a break despite the fact that it was so long that each of the tracks would hold 75 cars.

"Recent Developments in Shooting Coal" was then presented by J. E. Tiffany, explosives engineer of the U. S. Bureau of Mines, Pittsburgh, Pa. He said that improved results had been obtained by using $1\frac{1}{4}$-in. instead of $1\frac{3}{4}$-in. cartridges. However, when attempts are made to use cartridges of smaller diameter, deterioration sets in and there are delays in detonation. The U. S. Bureau of Mines, he said, was not prepared to say anything for or against the use of rock dust as stemming.

J. J. Rutledge, chief engineer, Bureau of Mines, State of Maryland, Baltimore, Md., said that he had obtained better coal by the use of rock-dust stemming. He had hoped to rock dust the face with the stemming but he had not obtained that result.

At the request of the chairman, Mr. Forbes described the work of the safety instruction department of the U. S. Bureau of Mines. Mr. Rutledge then gave a description of new methods of mining in the mines of northern Illinois, in Oklahoma, at Paris, Ark., and in the Helena-Straven mine, of Alabama. Mr. Rutledge expressed himself greatly interested in the uniformity with which the breaks in the roof occurred. They overhung the goaf at an angle of about 60 deg. to the horizontal. T. F. Downing, of the Edward V. D'Invilliers Engineering Co., said that the difficulty with longwall at one place had been that the draw rock, which was 4 ft. thick and overlaid by sandstone, would break back of the coal face, leaving a most treacherous condition to be met when the mining work progressed.

In the election which followed, practically all the last year's officers were re-elected by acclamation. The offi-

**Designed to Hoist 1,500 Tons an Hour**

Today we figure in hourly capacity rather than in daily output and yet our figures are as large or larger than they used to be in earlier days. This Nemacolin headframe handles at present only 4,600 tons daily but 15-ton skips with cylindro-conical drums could easily raise 12,000 tons daily when orders come from headquarters and more men are employed.

cers for the ensuing years are: R. M. Lambie, president; Thomas J. Downing, Jr., Philadelphia, Pa.; George Wolfe, Beckley, W. Va.; C. C. Morfit, Welch, W. Va.; E. S. Wade, Power, W. Va., and R. L. Kingsland, Fairmont, W. Va., vice-presidents; Frank Haas, Fairmont, W. Va.; W. E. Fohl, Pittsburgh, Pa.; R. F. Carson, Huntington, W. Va., and W. E. E. Koepler, Bluefield, W. Va., members of the Executive Board; R. E. Sherwood, Charleston, W. Va., secretary-treasurer.

The resolutions included one urging a continuance without restriction of the safety work of U. S. Bureau of Mines.

### Outlines Progress of Rock Dusting

At the banquet, which was attended by about 200, addresses were made by C. W. Riggs, I. C. White, E. Steidle, R. D. Hall, R. M. Lambie, D. C. Kennedy, C. R. Jones and J. T. Ryan. Mr. Steidle's address was on the "Present Status of Rock Dusting in the United States" and described the rapid progress in rock dusting in the various coal-producing states of the Union saying:

"Those who have followed the rapid progress in the art of rock-dusting will agree that opinion crystallized during 1924 and 1925 in support of this remedy for coal-dust explosions. Up to 1924 only one company in America practiced rock-dusting on a large scale. At present no less than 211 mines are rock-dusted, or approximately 4 per cent of the total number of bituminous coal mines in the United States, or in other words 11 per cent of the total annual production. Of these mines 63 are in Pennsylvania, 20 in West Virginia (about 2 per cent of the total number of mines), 8 in Alabama, 3 in Colorado, 21 in Illinois, 5 in Indiana, 2 in Kentucky, 13 in New Mexico, 3 in Ohio, 2 in Oklahoma, 21 in Utah and 49 in Wyoming.

"A total of about 1,000 miles of entry have been dusted. Pennsylvania leads with about 400 miles, and West Virginia has about 100 miles of dusted entries. In each case there is a sense of security, which not only the operator feels, but the miner also. The majority of the mines rock-dusted in West Virginia are in the Fairmont district. Several mines are rock-dusted in the Logan and Pocahontas fields, whereas none, according to recent reports, have been rock-dusted in the New River field."

R. D. Hall spoke on the importance of sedulously cultivating good public relations. There were, he said, perhaps only about 150,000 persons who had investments in coal, and with their families there were perhaps only 500,000 persons. These were faced by 105,000,000 consumers. It was not well to run the business without meditating on what those 105,000,000 were thinking and without so handling our business affairs that this large mass of people would be in accord with us. This was an important matter, he added, for citizens of a democracy voted as they thought. Not so much by propaganda as by a system of operation calculated to earn public approval could fair legislative action be attained.

From R. M. Lambie came a constructive talk relative to the progress of mine-accident prevention in West Virginia. He said in effect:

A train of 50-ton cars stretching from New York City to Omaha, Neb., represents West Virginia's coal production in October, and a train of 50-ton cars reaching from Charleston to Kenova the state's daily coal output last month. In 1914 the state produced 73,999,999 net tons in the fiscal year compared to 110,000,000 net tons in 1925.

From 1914 to 1919, inclusive, the mine accidents in the state totaled 2,571. The tonnage mined in this span of years was 499,786,380 net tons, an average of 194,394 tons per fatality. From 1920 to 1925, according to the chief, there were 2,349 fatalities or 222 less than the preceding six years, and during that period 570,239,193 tons were produced, making an average production of 242,758 tons per fatality. A train 24 miles long carrying coal was produced for each fatality from 1914 to 1919, inclusive. A train 30 miles in length represented each fatality from 1920 to 1925, inclusive, which represented an increase of six miles in length compared to the previous five-year period.

The ratio of fatal accidents per 1,000 men employed inside of the mines for the period from 1914 to 1919, inclusive, was 5.83. From 1920 to 1925, inclusive, this ratio was reduced to 3.82 per 1,000, or two lives saved on every 1,000 employed.

In tracing the progress of the state's coal mining activities Mr. Lambie said that in 1863, West Virginia produced enough coal to fill a train of cars that would reach 55 miles, but during last year the train that would hold the coal produced would be 15,000 miles long.

In describing the new safety plan adopted in the state, Mr. Lambie said that by an appropriation passed at the last session of the legislature, five safety instructors are to be placed in various sections of the state, whose duty it will be to instruct the coal miners in the five different regions in safety work. Mr. Lambie said that West Virginia was the first state in the Union to inaugurate this first big forward step in safety work and added that the U. S. Bureau of Mines had assigned William Forbes, of Huntington, its division engineer, to assist in the work.

### Visits Nemacolin Operation

The institute on the second day of the meeting, Nov. 25, visited Nemacolin, taking the train to Huron and crossing by the rope ferry. The mine at Nemacolin is operated by the Buckeye Coal Co., a subsidiary of the Youngstown Sheet & Tube Co. It is planned for a tonnage as large as that attained in any mine in the country though just at present the output is only 4,600 tons daily. It can, however, hoist with its cylindro-conical drums, when the workings are brought to their ultimate production, 12,000 tons in an 8-hr. day or even more. The coal is loaded into 15-ton skips by rotary dumps. The man hoist is an electrically operated elevator controlled either from the elevator itself or the main hoist room. A rope haul operated by remote control from the tipple moves the railroad cars past the loading point.

The main shaft bottom is concrete-lined, 25 ft. wide, 17 ft. high and 1,400 ft. long. It contains three tracks for empties, one for loads and one for shunting. The car haul will handle a 100-car trip, the 100 cars passing through the rotary dumps without uncoupling.

The visitors in company with C. M. Lingle, general manager, saw the town, one of the well-appointed houses, the school, the motion-picture house, the tipple, the shaft, the big shaft bottom and the skip-filling arrangements. A bountiful lunch was served by the visitors in the passage which crosses the side track where are the dispatcher's room and the foreman's office and shower.

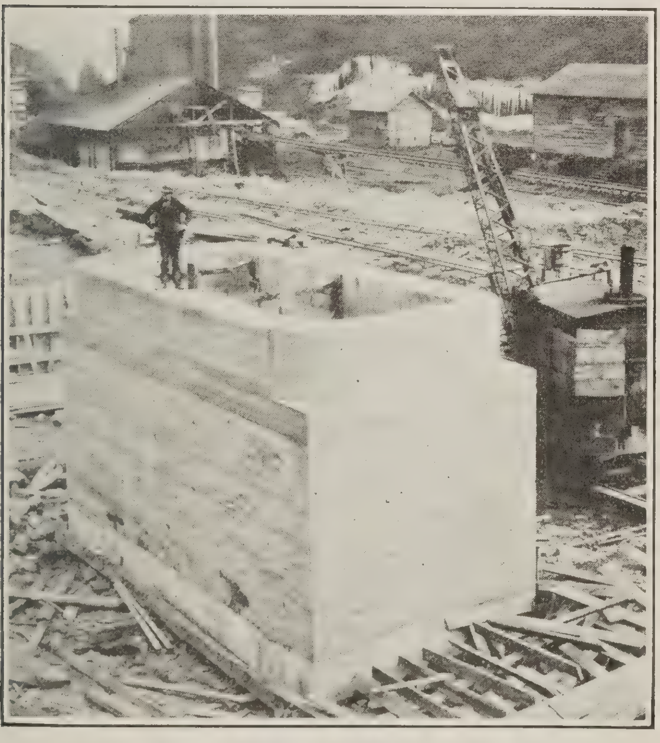
# Why Do So Many Concrete Shaft Linings Fail?

### Experts Before Engineers' Society of Western Pennsylvania Blame It on Water Percolating Through Porous Walls and Then Freezing There

THE DESIGN AND METHODS of constructing concrete linings of coal-mine shafts in this country must be changed—at least under certain conditions. The degree to which those alterations must be made depends upon the quantity of water outside the shaft and the range of temperatures below the freezing point within. This is the conclusion arrived at by the mining section of the Engineers Society of Western Pennsylvania at a bi-monthly meeting, in Pittsburgh, on Nov. 24, at which N. G. Alford, vice-president of Howard N. Eavenson & Associates, mining engineers, read a paper on "Failures of Concrete Shaft Linings at Pennsylvania Bituminous Coal Mines," covering the failure of 30 concrete shafts in a survey of 106 such openings which will appear in a later issue.

This meeting was well attended and the discussion lively, being participated in by men representing the coal, the railroad and the construction industries and also the Portland Cement Association.

In one of the typical shaft lining failures mentioned in Mr. Alford's paper, disintegration of the concrete was complete in a 4-in. curtain wall, leaving nothing but the reinforcing. H. M. Ernst, general superintendent of the Pittsburgh Terminal Coal Corporation, pointed to this fact as proof that hydrostatic pressure probably plays only a minor rôle, if any, in the failure of concrete linings. Mr. Alford thought the failure might have been due to the thinness of the curtain wall. C. H. Dorsey knows of a curtain wall erected in 1917 which has since failed though it was 12 in. thick. He believes this failure was due to the wide variation of temperatures on the two surfaces of the curtain wall which separates a downcast from an upcast. He was backed up in this statement by Mr. Hopkins who pointed to the setting up of severe stresses in the concrete by such variations.



**This Shaft Sunk on Edge of Sunny South**

Shaft sinking at No. 261 or Caretta mine of the Consolidation Coal Co. H. N. Eavenson declares that failures have been few in the southern West Virginia mines because the frost to which they are exposed is less severe than in more northern climes.

F. R. McMillan, of the Portland Cement Association, told the mining men not to be discouraged by the fact that 30 out of 106 shaft linings in Mr. Alford's survey have been reported as distinct failures. That record is little worse than that of other structures exposed to water, as reported by a committee of six which has been engaged during the past fifteen months in studying the causes of disintegration of concrete in various installations. He sees the possibility of some shaft linings being subjected to hydrostatic pressure of several hundred feet head.

He claims that practically 90 per cent of disintegration is due to the effect of frost on moisture in porous concrete, which is caused by improper proportioning of the mix and improper handling. Voids must be filled with an impermeable cement paste, which is possible only when a low water ratio is used and the paste is thoroughly manipulated. Coarse aggregate when used in large quantities, tends to segregate and produce a weak concrete.

Carl Weber, of the Weber Engineering Corporation, New York City, blames most failures upon cost-shaving, which he thinks in responsible for the construction of linings of less thickness and strength than are actually required. He has spent four years in the study of concrete linings in European countries. There, failures are almost unknown and there, also, he has seen one concrete shaft which, though forty years old, shows no signs of weakening. The shafts are of circular section and the linings are built thick. He would like to see this country follow this practice, and he doesn't see why we stick to the rectangular section which is the weakest of all the sections in use. Drawn out by a question by Mr. Hopkins, Mr. Alford stated that seven or eight of the thirty failures in his survey were in elliptical shafts.

Howard N. Eavenson believes that freezing of water within the shaft must cause most of the trouble because few failures of shafts at southern West Virginia mines have been noted whereas Somerset County, Pennsylvania, where the winters are severe, is believed to have had more failures than the western part of Pennsylvania. Protection against water is imperative. He doubts whether concrete, by and large, will last as long as wood in shaft linings judging by present indications. He feels that concrete will not do and looks to brick and wood as alternatives.

Mr. Watson believes in monolithic construction where possible, and in extending the present limits of sections where concrete structures must be built in stages. He has cast a 25-ft. high monolithic pier, embodying 175 cu.yd. of concrete, in 10 hr. He inquired as to the height of sections poured as monoliths in the construction of shaft linings and was told that 5-ft. sections are poured in general practice. He thinks the section should be increased to as much as 25 ft. When told that the forms would not stand the pressure created by sections of that height, he countered with the suggestion that the forms be made strong enough.

W. A. Weldin, consulting engineer, Pittsburgh, Pa., noted that nearly all of the concrete failures reported by Mr. Alford were in downcasts. For every downcast there is likely to be an upcast the lining of which has not been reported as having failed. For this reason freezing must be looked upon as the all-important agent of destruction and hydrostatic pressure and bending movements should be regarded with less seriousness. The fact that the linings of shafts sunk in the earlier days, when the use of water rings and bleeder pipes was universal practice, have failed to a lesser extent than those of a later period is proof that shaft linings must be completely drained. Road paving in former years met with the same relative failure until rich mixtures were employed.

### Reline Timber Shaft with Concrete

The H. C. Frick Coke Co. was represented by A. E. Duckwall. His company has thirty-seven concrete-lined shafts of which nineteen are downcasts and eighteen upcasts. The latter are more or less wet but none has failed. Of the nineteen downcasts, however, eight have failed. Six of these were constructed before 1921 and two after. He believes in relining timbered shafts with concrete though the cost of the latter is about 15 per cent more. Timber lasts about ten years in the coke region; one concrete shaft has been in since 1908. His company uses "fluxite," a compound which makes the mixture more plastic with the use of less water.

C. H. Dorsey, of the R. G. Johnson Co., shaft and slope contractors, would substitute brick for concrete in the lining of shafts at a 50 to 75 per cent greater cost. Water would tend to seep through the joints between the bricks, to be sure, but proper drainage would minimize the water trouble and the bricks (vitrified) would not spawl. Carl Weber does not favor the use of brick, partly because of the difficulty of getting a good setting but chiefly because frost might penetrate to a depth equivalent to the width of the face bricks.

F. A. McDonald, general superintendent of the National Mining Co., used brick in the relining of one of his failed shafts because only by this means could the job be completed with continued operation of the mine. In putting in the brick lining particular attention was paid to drainage although no great quantity of water was encountered. A comparatively small flow of water, however, is ultimately as serious as a large influx. He has made use of boreholes, located 4 or 5 ft. from the lining with rather satisfactory results, as a means of back-draining. He leans toward the use of concrete in preference to brick.

The Hillman Coal & Coke Co. has four concrete-lined shafts, sunk by contract, in which no failures have been noted. M. E. Haworth, chief engineer of this company, stated that a possibility exists that stresses may be developed in a shaft lining greater than those which concrete will stand.

Mr. Hopkins called attention to the possibility—which may be unlikely but which will bear investigation—of concrete in shaft linings failing by crushing due to the absence of expansion joints.

Some pointed remarks were made regarding the mixtures of concrete used in the linings which were reported in Mr. Alford's survey as having failed. These mixes varied from 1-3-5 to 1-2-4. A. C. Irwin, of the Portland Cement Association, claims that a 1-2-5 mix is not concrete. He cautioned against the use of a high water ratio and decided that the proportioning and handling of concrete in the lining of shafts must be changed since past practices have not produced an impervious concrete. E. T. Gott, Dravo Contracting Co., said that a 1-2-3 mix is coming in place of the 1-2-5 mix.

Mr. Gott mentioned the use of back-lining to stop the inflow of water into a shaft. His company sunk a shaft to a salt deposit near Detroit. The strata made several thousand gallons of water an hour during the sinking operations. By using a steel-plate jacket on the outside of the lining it was possible to cut down this inflow through the lining to 7 gal. per hour.

Mr. Weber says it is "all right to recommend" rich mixtures but the plan is of no avail without rigid inspection. This is difficult to obtain. Integral waterproofing compounds should be used. Percolation, in any case ,is hard to stop.

Someone asked whether any way has been devised to mend a spawled lining without pouring a new face—an expensive procedure that often gets doubtful results. Mr. Weber answered that the cement projecting machine offers the only known solution of this problem.

Mr. McDonald wondered whether slope linings are subjected to the same action as shaft linings. Mr. Alford remarked that two concrete slopes included in his survey are giving satisfactory results. Mr. Weber suggested the use of clay for grouting in some cases. He told of having applied two years ago a mantle of clay over a concrete slope lining at the Langeloth mine of the Langeloth Coal Co., Burgettstown, Pa., which thus far has sealed off water from the concrete. Apparently slopes can be drained easily.

### Use Grouting to Aid Sinking

In his paper Mr. Alford stated that his survey includes no reports of successful grouting operations. Grouting in one or two cases under Mr. Eavenson's observation has done no more than to chase water from one point of contact with the shaft lining to another. Grout injected through the lining of one shaft near Welch, W. Va., traveled 3,000 ft. and plugged water wells. At another shaft 1,600 sacks of cement were used in a grouting operation which did not entirely stop the flow. Several other men presented views which substantiated the conclusions that grouting should be used only as an aid to sinking.

Mr. Weber parried the condemnation of grouting which had been made by other speakers. Watery grout is not grout. It should be a plastic material applied under heavy pressure. He knows of one European circular concrete shaft 2,700 ft. deep which has been so successfully grouted as to stop all flow from strata bearing much water. The long Swiss tunnels have been made waterproof by grouting.

Mr. Weber drills grout holes at such an angle as to pierce a water-bearing stratum at a point some distance outside of the periphery of the shaft. He extends the grout as much as 40 ft. radially outside of the shaft and uses pressures up to 400 lb. In grouting lined shafts he works from the bottom up. "Grouting should not be a gamble" is his conviction.

# Coal Mining Institute of America Plans Important Meeting

UNDERGROUND COAL LOADING, mine timbering and new systems of coal mining are the principal subjects in the program arranged for the thirty-ninth annual meeting of the Coal Mining Institute of America at Pittsburgh, Pa., Dec. 9, 10 and 11. This meeting of mining engineers and others directly interested in the technical problems of coal production is expected to attract its usual large attendance of men from all over western and central Pennsylvania, parts of West Virginia and nearby coal regions. A great many questions that vex those engaged in actual operation of mines will be given full treatment at question box sessions. This program is topped off by a banquet at which Scott Turner, the new director of the Bureau of Mines, will speak.

The program in detail for the two-day meeting and the trip to the experimental mine follows:

## WEDNESDAY, DEC. 9

### Morning Session, 9 a.m.

Reports of the executive board.
Secretary-treasurer's annual report.
(Including list of deceased members for 1925)
Election of new members.
Election of six new tellers (for 1926).
Report by president on mail ballot.
Election for new officers for 1926.
Address by President Nicholas Evans.
Appointment of resolutions committee and auditing committee by the president.

### GENERAL DISCUSSION ON COAL LOADING MACHINERY

*Paper No. 1:* "Coal Loading Machinery, Its Actual Accomplishments to Date," by Walter M. Dake, Franklin, Pa., consulting engineer of the Joy Machine Co. (Accompanied by lantern slides.)

*Paper No. 2:* Same subject as above by Charles C. Whaley, Myers-Whaley Co., Knoxville, Tenn.

### Afternoon session, 1:30 p.m.

Motion Picture: "The Making of Wire Rope," showing the complete process, by John A. Roebling's Sons Co., Newark, N. J. (Through the courtesy of Frick & Lindsay Co.)

### QUESTION BOX

Leader—Richard Maize, Uniontown, Pa.

*Question No. 1:* "What new work has been done in recent years to prevent or reduce mine accidents?" From Pittsburgh, Pa.

*Question No. 2:* "Do prize competitions in first aid work, as now conducted, defeat the purpose intended, by laying too much stress on the development of crack teams, rather than general training for the mass of employees?" From Grindstone, Pa.

*Question No. 3:* "With coal lands at the maximum price per acre (in the coke region) is it economical to leave a water barrier of 100 ft. of coal adjacent to a worked-out mine which lies at a higher elevation?" From Pittsburgh, Pa.

*Papers No. 3 and 4:* "Coal Loading Machinery, Its Actual Accomplishments to Date," by E. H. Johnson, Columbus, Ohio, consulting engineer for the Coloder Co., and John M. Christline, Ford City, Pa., consulting engineer for the McKinlay Mining & Loading Machine Co. of Point Pleasant, W. Va.

### ANNUAL BANQUET
at 6.30 p.m.

At McCreery's store (ninth floor), Corner Sixth Ave. and Wood St. Toastmaster—President Nicholas Evans.

The speakers will be Jesse K. Johnston, Bolivar, Pa.; Director Scott Turner, U. S. Bureau of Mines, Washington, D. C.; Col. C. H. Birdseye, U S. Geological Survey, Washington, D. C.

## THURSDAY, DEC. 10

### Morning Session, 9 a.m.

### General Discussion on New Systems and Phases of Coal Mining Practice

*Paper No. 5:* "Recovery of the Big Vein Pillars in the Georges Creek Region," by Dr. J. J. Rutledge, chief mining engineer, Maryland Bureau of Mines, Baltimore, Md.

*Paper No. 6:* "Modern Practice in Underground Substations," by C. H. Matthews, mining engineer of the Westinghouse Electric and Mfg. Co., East Pittsburgh, Pa.

### QUESTION BOX

Leader, Wm. L. Affelder, Pittsburgh, Pa.

*Question No. 4:* "Is the arcing of electricity between steel rails and steel ties likely to cause a mine fire?" From Pittsburgh, Pa.

*Question No. 5:* "What items should be entered on a coal company's cost sheet? What constitutes what is known as strictly operating cost?" From Huntington, W. Va.

*Question No. 6:* "Discuss ventilation in single entry work. What is the best method especially where new methods of mining are being tried out?" From Baltimore, Md.

### AFTERNOON SESSION, 1 p.m.

### General Discussion on Mine Timbers

*Paper No. 7:* "Our Mine Timber Supply in Pennsylvania, Also in Other Coal Producing States," by Prof. H. S. Newins, department of wood utilization, State College, Pa.

*Paper No. 8:* "What Some Coal Companies Are Doing to Replenish the Mine Timber Supply," by Newell G. Alford, consulting engineer, Pittsburgh, Pa.

### QUESTION BOX

Leader, Thomas G. Fear, Indianola, Pa.

*Question No. 7:* "What is the best practice for the blasting of coal for mechanical loaders? Do they have any decided effect on lump coal?" From Uniontown, Pa.

*Question No. 8:* "Is scientific management applicable to the coal mining industry and is there anything the coal mining industry should learn from manufacturers?" From Thomas, W. Va.

*Question No. 9:* "Is it safe practice to use open lights in so-called non-gaseous coal mines?" From Pittsburgh, Pa.

Treatise by J. E. Tiffany, U. S. Bureau of Mines.

## FRIDAY, DEC. 11

Inspection trip to United States Bureau of Mines Experimental Mine, Bruceton, Pa., in charge of Managing Directors J. W. Paul and A. C. Fieldner.

The program for the visit at Bruceton will include the following:

*Experimental mine*

1. Inflammation of coal dust by open flame and by electric arc.
2. Explosion of coal dust ignited by natural gas, and stopped by rock dust.
3. Demonstration of rock dust barriers.
4. Demonstration of coal dust explosion in small portable field gallery.
5. Gas ignition in 12-in. steel tube showing slow propagation when lighted at open end.

*Explosives section*

1. Permissible explosive shot in large gallery in presence of coal dust.
2. Black powder shot in gallery with coal dust.
3. Ignition of keg of powder by electric current.

*Safety service*

1. Rescue crew with three types of breathing apparatus enter mine after explosion, followed by men with all-service gas mask and safety lamps.
2. Rescue crew obtains sample of air for analysis by gas chemist.
3. Gas mask man carries CO detector and tests air and reports. Give explanation of the CO detector.
4. Show workings of Burrell gas detector and test sample.

*Exhibits*

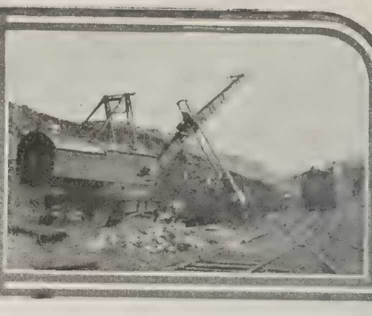
Breathing apparatus, CO detector, Burrell gas tester, Orsat apparatus.

*Flame Lamps*—Wolf and Koehler.

*Electric Lamps*—Edison, Wheat, Concordia, Eveready Flash lamp.

*Shot-firing Equipment*—Davis, duPont, MSA, Eveready.

# News Of the Industry



## Operators Reject Pinchot Plan To Terminate Anthracite Strike; Lewis Is Willing to Negotiate

Insisting that the bases suggested offered no ground for a permanent settlement, the anthracite operators, at a meeting in Philadelphia on Monday of this week, flatly rejected a program for a renewal of negotiations to end the hard-coal suspension proposed by Governor Pinchot of Pennsylvania last Saturday. The United Mine Workers had already rejected one plank in the Governor's platform which called for an immediate resumption of mining, but had agreed to again meet with the operators and discuss the formulation of a new wage contract along the lines laid down by Mr. Pinchot.

The operators in their rejection denounced the Pinchot program as a policy of expediency to which they could not subscribe. They also outlined the terms upon which they were ready to resume negotiations. These terms, submitted to the miners a fortnight ago through an intermediary, rumored to have been W. A. Glasgow, counsel for the United Mine Workers, called for an immediate resumption of mining, the submission of any points upon which agreement could not be reached within 30 days after negotiations had been started to an arbitration board, and a five-year contract, subject to annual revision — if necessary — through direct negotiation and arbitration.

The Pinchot proposals came as the climax of a week of secret conferences and rumors. The operators started with a meeting at Philadelphia on Nov. 23, but no change from the position outlined in the preceding issue of *Coal Age* was announced. The following day a fillip of mystery was added to the proceedings when Mr. Lewis and Alvan Markle, chairman of the joint scale conference at Atlantic City last summer, conferred for several hours at the Union League Club in Philadelphia. Neither would discuss the subject of the conference, although Mr. Markle denied that it had any significance in so far as the present suspension was concerned. Late that same evening, however, Mr. Lewis wired District Presidents Golden, Cappellini and Mattey to meet with him and Vice-President Murray and Secretary Kennedy in Philadelphia the following day.

On Wednesday the Governor, who had twice summoned Mr. Lewis and Major Inglis to private conferences, again called in the leaders of the two sides. Once more the veil of silence descended, but it was rent two days later when publicity was given to the fact that the Governor had asked the scale committees to meet with him at Harrisburg on Saturday afternoon. This invitation the operators declined on the ground that it was impossible to assemble their committee on such short notice. Their position was made known in a telegram from Major Inglis to Governor Pinchot, reading as follows:

> In reply to your telegram, received late yesterday [Nov. 27], as I intimated to you over the telephone, I find it impossible to get the committee together for a conference at Harrisburg today. If you so desire, I will endeavor to arrange a meeting between you and our committee after Monday next to consider any proposition you may have to make. In my opinion, such a meeting is essential in order that we may know what you have in mind before entering into any joint conference with you and the miners' representatives. I think it advisable that any plan you have in mind be held confidential until both sides have had an opportunity separately to consider it.

### Must Make Concessions

"Neither miners nor operators," said the Governor, "can expect, nor ought to expect, to see this strike settled on their own terms. Both must make concessions. If either side attempts to hold out against a reasonable settlement for mere pride of opinion, anxiety to save its face, or the determination to insist on some point too small to be weighed against the enormous losses of the public, it will justly be held responsible for those losses, and its condemnation will be as great as its offense.

The Governor declared that he was ready to propose a specific plan which he believed offered a basis for settlement with justice to all parties. The provisions of this plan follow:

> (1) The prices of anthracite coal shall not, by reason of the present suspension, or of this agreement or any part of it, be increased by the operators beyond those scheduled for the year 1925.
>
> (2) This agreement shall be for not less than five years.
>
> (3) A board of investigation and award shall be established under this agreement, and shall continue during the life thereof. It shall consist of two men chosen by the miners, two men chosen by the operators, and three others selected by the four thus chosen. All necessary expenses of the board shall be borne equally by the miners and operators.
>
> (4) The Board of Investigation and Award shall investigate and determine whether or not, all factors of cost being duly considered, the operators can reasonably pay an increase of wages without increasing the price of coal. If the board shall find an increase of wages without any increase of price is justified, such increase shall be paid in such amounts and to such classes of employees as the board in its award shall determine. If it shall not so find, no increase of wages shall be awarded.
>
> (5) The Board of Investigation and Award shall meet and organize within thirty days and make and publish its award within six calendar months after it shall organize for business. Any increase of wages so awarded shall be in effect and date back to the day when the present suspension ends.
>
> (6) The original records of both miners and operators shall be open to the Board of Investigation and Award for the purpose of enabling it to reach its decision, but the records shall not be made public in such manner as to enable the facts concerning any individual company or any local union to be separately known.
>
> (7) When its award as to wages has been made, the Board of Investigation and Award shall forthwith proceed to investigate, determine and publicly recommend the most practicable and available method for avoiding suspensions of work in the anthracite mines and for assuring to the public an uninterrupted supply of anthracite coal. It shall also investigate, ascertain and recommend methods for increasing the efficiency and reducing the cost of operation of the mines.
>
> (8) Full recognition of the union (the check-off) shall not be granted by the operators, but any operator shall honor the voluntary individual written request of any miner to assign the amount of his present union dues, not exceeding $14 per year, and including neither fines nor assessments, as

### *Commerce Commission Takes New Action on Coke Rates*

The Interstate Commerce Commission, which several days ago canceled its permit to Southern lines to file tariffs establishing new rates on byproduct coke from Alabama to southern Michigan, has again reversed itself. A permit was issued Nov. 25 allowing the publication of such rates on five days' notice. The new permit, however, requires that the rates published under it shall expire Feb. 28 and makes the rate bases 75c. and $1 per ton over Chattanooga, instead of 50 and 75c., as originally proposed.

Proponents of the new schedules declared they were actuated by a desire to relieve fuel shortages arising out of the anthracite strike. Opponents retorted that the Birmingham people wanted to get rid of an accumulation of coke thrown back upon them as the result of the loss of steel business.

The Commission also has refused to suspend tariffs reducing rates from Clairton and other western Pennsylvania byproduct ovens to stations in Pennsylvania, Ohio, Indiana, Michigan, New York and Ontario. Beehive interests had protested the publication of these rates.

assignment for house rent, coal, powder and other mining supplies, and delinquent taxes, as now practiced. (Such dues are already so assigned in certain anthracite mines.)

(9) The adjustment of working conditions, as specified in the demands of the miners, and any other matters not here specifically mentioned, shall be referred back to the representatives of the miners and operators for settlement.

(10) The Board of Conciliation, established under the Roosevelt settlement of 1903, shall proceed at once to equalize wages as agreed upon in the strike settlement of 1923. Wages shall not be reduced during the life of this agreement below those provided in the last agreement unless as the result of such equalization.

(11) The present suspension shall end and the mining of anthracite coal shall be resumed at once.

The miners, after a meeting Sunday, outlined their position in the following letter from Mr. Lewis to the Governor:

Conscious of the imperative public need which prompted your proposals to the anthracite operators and miners for adjustment of the present controversy, the mine workers' representatives have given to the subject the most profound consideration. It is obvious that the interests of peace in the anthracite industry require consideration by both sides in a spirit of compromise and mutual concession. The mine workers regard your proposals for a settlement as being representative of the public viewpoint, and have every sincere desire now, as before, to terminate a distressing situation which menaces public health and well being.

I am, therefore, authorized by the Tri-District Scale Committee of Districts 1, 7 and 9, United Mine Workers of America, to advise you that on behalf of our membership we accept the proposals made by you as a basis of settlement. We stand ready at any time to meet in joint conference with the representatives of the anthracite operators to negotiate an agreement which shall encompass the points set forth by you.

We further advise that promptly following such agreement upon the part of the anthracite operators we will arrange for a resumption of mining at the anthracite collieries at the earliest possible date.

### Pinchot Praises Miners

Commenting on this letter, Governor Pinchot, who was in Pittsburgh at the time the miners' reply was handed to his secretary, praised the labor leaders warmly and declared that "the willingness of the miners to go without an increase of pay unless it can be granted without raising the price of coal to the anthracite using people of America sets a new high mark in wage disputes in the United States."

Formal notice of the rejection of his proposals was conveyed to the Governor in a letter signed by Major Inglis as chairman of the operators' negotiating committee. This letter read as follows:

Acknowledging your letter of Nov. 28, enclosing copy of the proposition which you laid before the meeting last Saturday afternoon and which you refer to the anthracite operators' committee for consideration:

As a first step, we have asked ourselves: Are the proposals you have submitted practicable? Will they end the present industrial strife in a way that will enable us for a long period of time to operate our mines, give employment to labor, hold prices at a reasonable level and give assurance of reasonable return on the investment? These questions are vital to the life of the industry, and the answer to them necessarily determines our answer to you.

You propose that prices shall not be increased and wages shall not be decreased for a period of five years, regardless of changed conditions. You suggest a board of investigation and award which, however, has power to do but one thing—increase wages. This is not arbitration and cannot be accepted as a substitute for real arbitration, in which proved facts would control.

You ask us to repeat the Jacksonville mistake of endeavoring to maintain high prices to pay high wages through the simple formula of writing these terms into a contract. An arrangement involving agreement on prices is clearly illegal. Furthermore, no producer of any commodity could in good faith bind himself to such a proposal. Prices are controlled by the law of supply and demand and cannot be maintained at artificial levels by arbitrary agreement.

You further propose that the board is to pass on the profits of the industry, and that irrespective of whether wages are just and fair, if profits permit, wages shall be increased. Without comment on the unsound theory that profits should fix wages (a theory that would operate against the employee as often as against the employer), it seems to us that it would have been more logical to suggest that if profits are excessive and labor well paid, prices should be reduced.

The check-off, condemned in principle by the Roosevelt commission in 1903 and refused by the Wilson commission in 1920, you now suggest that we accept by another name. By any name it is repugnant to reason and justice and a barrier rather than an aid to sound industrial relations. In theory only would assignments be "voluntary." In practice the system would result in coercion and intimidation. The check-off would not eliminate strikes, for the real effect would be to substitute the strike to force voluntary assignments for the "button strike" heretofore employed to force union membership. The confirmation of this lies in the finding of a federal court within the past few weeks that "the check-off system and its provisions are to prevent all non-union men from working in union mines and compel all workmen to become members of said organization, so that said organization shall have an absolute monopoly of all labor engaged in such industry."

Only on the ground of misunderstanding our seriousness of purpose and our desire to reach conclusions of lasting benefit can we account for proposals that so completely fail to meet the necessities of the situation. We note that your plan is satisfactory to Mr. Lewis and his associates. This is not surprising. Naturally, he agrees to the check-off and to continuation of high wages which can be further increased but not decreased by "arbifration."

Your telegram emphasizes the fact that you found it necessary to go ahead with a public meeting because of the extent to which the matters in controversy were charged with public interest. It is for that very reason, and because of the unwarranted increase imposed on the industry through your mediation two years ago, that the operators are now proceeding with the caution that the seriouness of the situation demands. We are not unmindful of the public interest, for that interest and the future welfare of the industry are so closely allied that disassociation is impossible. In striving for a settlement that shall provide for extended peace and for effective machinery to adjust wages, should economic conditions require, we are fighting for the rights of the public as well as those of the industry.

Two weeks ago, through an intermediary who came to us, we offered Mr. Lewis the following proposal:

(1) An immediate return to work at wages paid prior to the suspension.

(2) A resumption of negotiations to consider any modifications of the expired contract that might be urged by either party.

(3) A new contract for not less than five years to be formulated and signed. Any matters in dispute and not disposed of within thirty days after the resumption of negotiations to be referred to a board for settlement.

(4) The board to be composed of two operators, two mine workers and three persons, in every sense impartial, to be appointed by the Chief Justice of the U. S. Supreme Court, the Chief Justice of the Pennsylvania Supreme Court, and the presiding Judge of the U. S. Circuit Court of Appeals for the Third Circuit.

(5) Either party to have the right, once in twelve months—but not oftener—to ask for a conference to reconsider any of the terms of the contract. Matters still in controversy thirty days after the convening of any conference, to be referred to the board for settlement.

Here was a proposition for immediate resumption of work, under the terms of the expired contract, while the parties made one more attempt to reconcile their differences, and with provision for settling any disputes that could not be settled by negotiations. It made no restrictions, but left open to determination, based on the facts, all matters in controversy. Mr. Lewis summarily rejected it.

It is only on some basis that recognizes facts as the controlling influence that this controversy can be satisfactorily settled. The substitution of expediency is a policy to which we cannot subscribe. It is impossible for us to find in your proposals the basis of a sound and lasting settlement, and for the same reason they cannot be considered as a basis for conference and negotiation.

## *Broadens Scope of Emergency Rates To Eastern States*

About the time the anthracite operators were making known their rejection of Governor Pinchot's plan to end the strike the Interstate Commerce Commission at Washington announced further supplemental orders extending the scope of its decision opening up the New England and Middle Atlantic states to all-rail movement of coal from the Southern fields. The new rates, which are to become effective not later than Dec. 31, 1925, and expire April 30, 1926, are limited to prepared sizes (lump, egg and nut) and apply as follows:

(1) From all mines in the New River, Tug River, Pocahontas and Clinch Valley District No. 1 fields to all points in New Jersey and the New England states, other than destinations covered by original orders, rates $1.10 above the Clearfield basis.

(2) Clinch Valley District No. 2 to Baltimore & Ohio, Pennsylvania and Long Island R.R. stations and to destinations covered under paragraph (1) the same basis as applicable from Pocahontas and Tug River.

(3) From all mines in the Kanawha, Coal River, Logan, Kenova and Thacker districts to all points on B. & O., P. R. R. and Long Island railroads covered by original order of July 22, 1925, and to all points in New Jersey and the New England states, rates not more than 25c. per ton above the New River-Pocahontas basis.

(4) From all mines on the Big Sandy division of the Chesapeake & Ohio Ry. in Kentucky to destinations described in preceding paragraph, rates not more than 40c. above the New River-Pocahontas basis.

(5) Semi-anthracite from McCoy and Merrimac, Va., on Virginian Ry., and Pulaski to Vicker, Va., inclusive, on Norfolk & Western Ry., rates not exceeding rates on Pocahontas coal to destinations embraced in paragraph (2).

The Commission, however, declined to extend the application of these rates to the movement of mine-run all-rail.

## Coal-Mine Accidents Kill 141 in October; Rate Still Declining

Accidents in the coal-mining industry of the United States in October, 1925, caused a loss of 141 lives among the employees, according to information furnished by state mine inspectors to the United States Bureau of Mines. One man was killed by fall of rock in an anthracite mine; all of the other fatalities occurred at mines producing bituminous coal. The October fatality rate for bituminous mines was 2.63 per million tons as compared with 3.03 for September and 2.89 for October last year. The output of bituminous coal in October was 53,203,000 tons.

During the first ten months of the current year, the production of bituminous coal was 419,371,000 tons while the anthracite output was 61,741,000 tons, including about 120,000 tons obtained from dredges. The 10-month fatality rate per million tons for bituminous mines was 3.26 as compared with 4.12 for the same period last year; the anthracite rate was 6.30 for the present year as against 5.46.

Current records covering "major" disasters, that is, disasters in which 5 or more lives were lost, show 10 separate accidents with an aggregate loss of 198 lives in 1925 as compared with last year's 10-month record of 9 separate accidents with a total loss of 452 lives. The per-million-ton death rate for both anthracite and bituminous mines based exclusively on these major disasters was 0.41 this year as compared with 0.96 during the first ten months of 1924.

An examination of the causes of the fatalities reported thus far in 1925 and a comparison of the record with that for January to October, 1924, shows slight reductions in the per-million-ton fatality rates for falls of roof, haulage and electricity and a much more notable decline for explosions of gas or coal dust. The rate for accidents from explosives remained unchanged. The comparative rates were as follows:

| | Jan.-Oct., 1924 | Jan.-Oct., 1925 |
|---|---|---|
| All causes | 4.328 | 3.649 |
| Falls of roof and coal | 1.830 | 1.779 |
| Haulage | .618 | .590 |
| Gas or dust explosions | 1.097 | .557 |
| Explosives | .174 | .170 |
| Electricity | .147 | .137 |

### *Serve Dinner to Twelve In Firebox*

What is said to be the largest powdered coal burner in the world was completed recently at the Post Street heating plant of the Puget Sound Power & Light Co., Seattle. The firebox is 18 ft. long, 12 ft. wide and 16 to 20½ ft. high. Upon completion of the installation, Chas C. Moore & Co., contractors, gave a banquet in the spacious firebox to officials of the power company. Covers were set for twelve persons and there was room for as many more.

## British Producers Study American Methods

In order to study at first-hand American mining methods and equipment, in the hope of being able to adapt some of them to the solution of their own problems, a group of British coal producers are now touring this country. The party includes C. C. Reid, general manager, Fife Coal Co., Scotland; William Telfer, general manager, Coltness Iron Co., Scotland; S. Walton Brown, general manager, Seghill Colliery Co., Northumberland, England; M. J. Foggo, manager, Cannock Chase Colliery Co., Staffordshire; C. Howson, agent, Dorman, Long & Co., Durham; A. Robinson, manager, Simon Carves Co., Manchester; Mr. Grant, of the Evans & Reed Coal Co., Ltd., London; John S. Morris, chairman, D. L. Flack & Son, Ltd., London; Hugh Wood, managing director, Hugh Wood & Co., Ltd., Newcastle-on-Tyne, and C. Rogerson, Blantyre Engineering Co., Blantyre, Scotland.

For the purpose of observing the latest developments in American coal-mining machinery the Britishers will visit the producing fields of Pennsylvania, West Virginia and Ohio. They will be guests of the Bureau of Mines at the Pittsburgh Experiment Station, where a chemist of the British Mines Department is now engaged in research work under a co-operative agreement between the British and American mines departments, and also will inspect the low-temperature carbonization plant of the Ford organization at Detroit.

## Coal-Mine Fatalities During October, 1925, by Causes and States

(Compiled by Bureau of Mines and Published by *Coal Age*)

[1] Only one fatality, owing to strike in anthracite mines.

# Lewis Letter Mystifies Washington; Attempt to Force President's Hand Is Likely to Prove a Boomerang

**By Paul Wooton**
Washington Correspondent of *Coal Age*

John L. Lewis' letter to the President caused a decided stir in Washington. No one seems to be able to fathom just what the move means. Mr. Lewis evidently concluded that the time was ripe to play a card, but apparently no one is able to figure out just what trick he expects to take. The letter itself has done nothing to unravel the complicated plot of the coal drama; on the contrary, it has added new suspense to the story.

In this situation full of uncertainties the greatest uncertainty is Mr. Lewis' mind. Seldom has a labor leader kept his own counsel so completely during a strike. To predict the outcome of his threat requires a knowledge of his plans, but no inkling of his strategy has leaked out. If he really means to call a soft-coal strike it is obvious that the best time would be later in the winter when the demand for anthracite will have reached its maximum.

Thus far the real pinch of the anthracite strike has not been felt. The first month of idleness was no more than enough to take up the usual thirty days' slack time in the working year. The second month was no more than enough to liquidate the heavy stocks built up in anticipation of the strike. The third month of idleness was enough to force some use of substitutes, but the real deficit does not begin to accrue until the beginning of the fourth month. December hardly is the time to play the trump card. Just why Mr. Lewis is fingering that card and threatening to play it at this time is not understood. It hardly can be with the thought of forcing the administration to try to pull his chestnuts out of the fire before Congress meets. The actual effect on the administration seems to be just the reverse. The Lewis letter is calculated to make the President more determined than ever not to intervene.

### Lewis May Cut Himself

The thought is advanced that the letter may have been intended to influence the President's reference to coal in his message to Congress. If that was the object it is more likely to sharpen rather than blunt the expected recommendation that added powers be given the executive to handle emergencies in coal—the very thing to which the United Mine Workers object most strenuously.

Most of those who are following developments closely express the opinion that it is idle to speculate on the mental processes of the mine workers' president. It is apparent that he has added one more name to the illustrious list of those he has flouted. It is curious how one after another of public men with whom he has had to deal have had to abandon friendly co-operation for out-and-out opposition. These men found that the United Mine Workers cooperate only when it is to their advantage.

The feeling is that the administration went far enough on behalf of the miners when it counselled the union employers against undertaking another fight with the union at the time the Jacksonville agreement was under discussion.

As this is written no intimation has been given out as to the nature of the reply which the President will make to the Lewis letter. It seems certain, however, that the President will reiterate that the enforcement of labor agreements is not a responsibility that he properly can assume. None will be surprised if he calls attention to the fact that the courts are the public agency to which parties to private contracts may appeal in cases of dispute. He is expected to add that if different relationships between the coal industry and the executive branch of government are desired an act of Congress must be enacted.

---

## St. Louis Coal & Iron Co. Is Reorganized

The Midland Coke & Iron Corporation, St. Louis, Mo., a reorganization of the St. Louis Coal & Iron Co., has taken charge of operations, James Duncan having officially relinquished his post as receiver of the old company's affairs.

The new corporation, recently organized under a Delaware charter, has acquired the blast furnaces, coke ovens and byproduct plants at Granite City for $3,000,000. The equipment originally cost the St. Louis Coal & Iron Co., $40,000,000. The property was sold at auction Oct. 20 and was bid in by C. H. Hand, of New York, representing bondholders. To this equipment the corporation is planning to add $3,000,000 in construction of a new blast furnace and power plant.

The officers of the new corporation are W. G. Maguire, of Chicago, president; M. D. Curran, St. Louis, vice-president; A. J. Mann, Chicago, treasurer; P. B. Nelson, Chicago, secretary, and L. A. Whitaker, St. Louis, assistant treasurer. Maguire and Mann held the same positions with the St. Louis Coal & Iron Co.

L. A. Busby, of Chicago, is chairman of the board, the other directors being John Henry Hammond, of Brown Brothers, New York; Alfred J. Kieckhefer, president of the National Enameling & Stamping Co.; C. D. Marshall, president of the Ritter Conley Co.; Breckinbridge Jones, chairman of the board of the Mississippi Valley Trust Co.; Clement Studebaker, president the Illinois Light & Power Co.; F. J. Lewis, James Duncan, George W. Buckingham and W. G. Maguire.

## Output Mounts Steadily At Non-Union Operations In Upper West Virginia

There is a steady increase in the non-union coal loading in northern West Virginia and there is little doubt that the United Mine Workers have lost their fight in that field. The largest daily non-union coal production in the region since the strike began April 1 was reached Nov. 25, when 1,960 carloads was produced. This big total was partly due to heavy output on the Monongah Division, B. & O., which was 1,052 cars, and on the Monongahela Ry., which reached a total of 447 cars.

The union mines loaded 886 cars of coal in the first three days of last week compared to 833 cars in the corresponding period of the preceding week. The union tonnage is confined almost entirely to Scott's Run, where the mines have been loading from 250 to 260 cars a day. At present this is the only remaining union stronghold in the 12½ counties of northern West Virginia. Some of the mines that worked on a union basis in the heart of the Fairmont field, especially on the Monongah Division, B. & O., it is rumored, probably will start to work on a non-union basis at a later date.

While there is no great shortage of labor in the region there is a decided tightening up at some of the plants. In fact some of the mines report that many loaders have left the field.

Officials of the Consolidation Coal Co. report that steady progress is being made at the Monongah, O'Donnell and Wyatt mines, which were reopened recently.

Van Bittner, special representative of the United Mine Workers in northern West Virginia, took another fall out of the non-union operators at a mass meeting attended by 4,000 persons in Carmichael Auditorium, in Clarksburg, early last week.

### "Not Really on Strike"

"The coal miners who were formerly employed by the Consolidation Coal Co., the Hutchinson Coal Co., the Clark Coal & Coke Co., the Bethlehem Mines Corporation and many other companies which abrogated their wage agreement are really not on strike," said Bittner, "but they are locked out, and with their wives and children are forced to undergo all the hardships of an industrial battle.

"If the United Mine Workers did nothing else but improve the conditions of safety in the mines of West Virginia, as they have in the mines of the Central Competitive Field, they have more than justified their existence. In the Central Competitive Field, the average number of men killed for the past 10 years per million tons of coal produced is 2.96, while in West Virginia, which has been principally non-union, the number of men killed per million tons of coal mined has been 4.87. In all the history of West Virginia mining, 1,546 coal miners have been killed by mine explosions in non-union mines (these include Monongah and Barrackville), while 41 men have been killed in mine explosions in union mines."

# Court Annuls I. C. C. Decree Prorating Private Coal Cars When Rolling Stock Is Scarce

The U. S. District Court at Philadelphia held on Nov. 25 that the order of the Interstate Commerce Commission providing for a pro rata distribution of privately owned coal cars among bituminous mines in times of railroad car shortage was "unjust and unreasonable and an unlawfully arbitrary exercise of power." The decision annulling the Commerce Commission order came as the result of suits brought by railroads, steel, iron, coal, coke and public service companies numbering nearly one hundred, asking that the order of the commission be set aside. The suits were heard by Judges Victor B. M. Woolley, of Delaware; J. Whitaker Thompson, of Philadelphia, and W. H. S. Thomson, of Pittsburgh.

The order was issued in September, 1924, and though dates when it was to go into effect were announced from time to time and later deferred it never actually became operative, as it was to apply only when there were shortages of railroad coal cars.

The commission based its order on the legal conclusion that the "assigned car rule," as practiced by the railroads, was an unjust and unreasonable regulation and practice.

### Attempts Regulation of Industry

The complainants contended that the order was beyond the scope of the commission's authority and the result of an erroneous conception of its powers. It was also contended that the order, in substance and intent, was an attempt to regulate the mining industry through distributing coal production ratably among all mines desiring to operate and that it deprived the plaintiffs of the value of their cars and of their right to have them used and operated in time of coal car shortage without compensation.

The opinion of the court, written by Judge Thompson, set forth that the right to the use of private cars was clearly recognized by the law, and that this "valuable legal right in the ownership of private cars, in which sums of money amounting to millions of dollars have been invested, furnishes the only means by which car owners can procure an adequate fuel supply in periods of recurrent car shortage."

### Decide Order is Unjust

"We conclude that the order of the commission is unjust and unreasonable and an unlawfully arbitrary exercise of power," says the decision; "that it undertakes by indirection to regulate the soft-coal industry in matters which do not constitute transportation service relating to commerce and are not within the regulatory power of the commission; that it assumes without authority of law to restrict the lawful right of the railroads to obtain by purchase or ownership of mines the supplies necessary to their operation in the service of the public; that the use of the railway fuel cars and private cars under the assigned car rule is not *per se* preferential; that there are not sufficient facts set out in the commission's report upon which to base findings of such discriminatory and preferential practices as to justify in this case; that it is confiscatory in violation of the Fifth Amendment of the Constitution in depriving the railroads of the use of their mines and the private car owners of the use of their mines and cars; that the order is, therefore, beyond the authority of the commission, without warrant of law, and null and void."

Under the prevailing system, which the court's order sustained, mines which own their coal cars are entitled to receive all of these and, in addition, an equal share of such railroad-owned cars as may be available on the system which serves them. If they are engaged in producing railroad fuel, they also are entitled to receive as many cars as the railroad requires.

The commission's legal representatives are expected to take an appeal from the decision and the question may finally be passed upon by the Supreme Court.

## *Industrial Coal Stocks Sufficient for 39 Days*

Coal stocks in the hands of industrial consumers on Nov. 1 totaled 67,837,000 tons, or sufficient to last thirty-nine days at the October rate of daily consumption, according to an estimate by the National Association of Purchasing Agents. On Oct. 1 the estimated stocks were enough to last fifty days.

Coal consumption in October is estimated at 53,737,000 net tons, industrial activity having reached a new high level in registering an increase of 26 per cent over September. Bituminous-coal output in October was 53,528,000 tons, compared with 46,661,000 tons in September. Only 78,000 tons of anthracite was made available for consumption in October, however, as against 8,845,000 tons in August.

## Navy Coal Bids Sought

Bids for supplying 80,000 gross tons of semi-bituminous coal from mines on the navy acceptable list for delivery at Hampton Roads will be opened Dec. 9 by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C. The coal is for use of naval vessels, delivery to be made between Dec. 9, 1925, and June 30, 1926, in quantities as required. Proposals on less than the entire quantity required will be considered.

---

A practical reorganization of the executive departments of the federal government would make possible an annual reduction of $250,000,000 in expenditures, Representative Wood, of Indiana, an influential member of the House of Representatives, believes. He thinks there is small prospect for Congress to agree on legislation specifying the exact form reorganization should take, but he feels there will be no great amount of objection to allowing the President more freedom of action in the grouping of executive agencies so as to obtain maximum efficiency.

# Bituminous Coal Loaded Into Vessels at Lake Erie Ports During Season to End of October

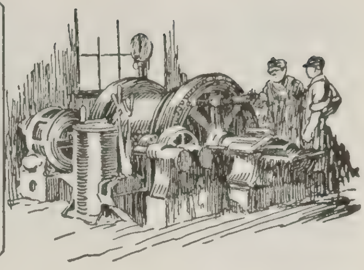
# Practical Pointers For Electrical And Mechanical Men



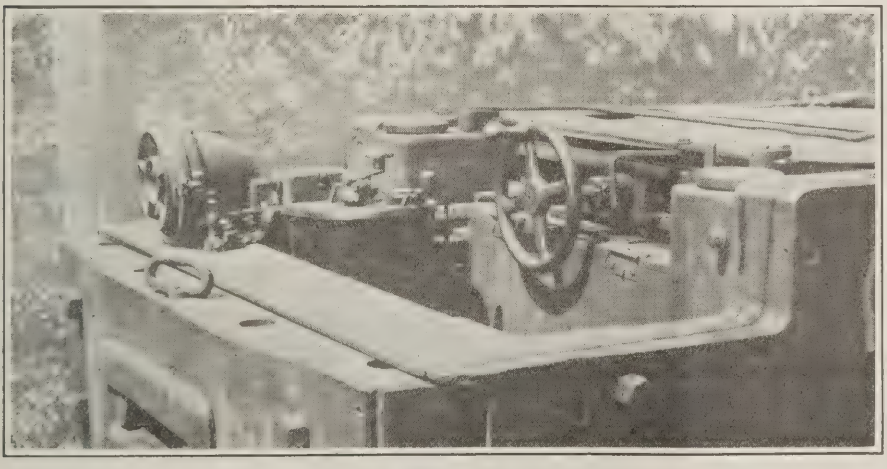
## Old Mine Locomotives Are Fitted With Contactor Control

Lower peak loads and reduced maintenance are the principal advantages afforded by the application of magnetic contactor control to mine locomotives. These advantages apply in the greatest measure to heavy locomotives such as used on the main hauls. Many companies are now removing the old type controllers from the 10- to 20-ton locomotives and installing contactors.

The accompanying illustration shows a 15-ton locomotive at a Kentucky mine on which magnetic contactor control has been installed. On this equipment the reverse cylinder is manually operated and is combined in a common inclosure with the master controller.

On an old locomotive it may be a difficult matter to find suitable space for the contactors. In this instance, the contactors, or magnetic switches, are mounted just below the brake wheel and are protected by a box made of ½-in. fibre. The material was used because, due to lack of clearance, an insulating lining is necessary. The box can be opened for inspection of the contactors by removing the side next to the brake wheel. This section is unfastened by pulling the pins out of the hinges.

The contactors of the control on this locomotive are not governed by the action of current-limiting relays, but directly by the hand-operated master controller. Fuses are eliminated on the locomotive. Protection against high demands and overloads is provided by an overload relay which is reset only by turning the controller handle back to the first point.



**Contactors are Mounted in a Fibre Box Under the Brake Wheel**

The original controller of this 15-ton locomotive has been replaced by a master controller and magnetic switches. The reverse cylinder is hand operated, and is in the same inclosing case as the master cylinder. Line fuses are replaced by an overload relay which is reset only by bringing the operating handle back to first point.

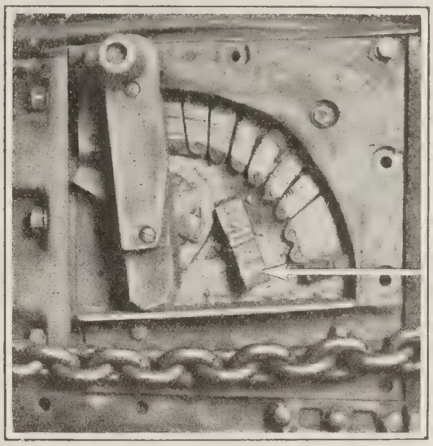
---

## Adding a Finger Relieves Controller Trouble

Burning of the power stud has been a source of trouble with the open-type mining machine controllers used by the Island Creek Coal Co., of Holden, W. Va. L. D. Thompson, chief electrician of direct-current equipment, believes that he has "clamped the lid" on this particular "bug."

He has tried out and is now equipping all such controllers with an auxiliary contact which shunts the current around the power-stud contact when the controller handle is in the running position. A locomotive controller finger is mounted on the face plate near the last or running segment. This finger makes contact with the strap, on the under side of the handle, to which the controller brush is connected. On the back of the face plate a solid connection is made between the power stud and the contact finger.

This arrangement does not entirely relieve the power stud of carrying current. It must still handle the starting current, which, however, due to its short duration does not cause serious heating or burning. The operating current, which caused the trouble, is afforded a parallel path around the power-stud contact.



**Mining Machine Controller Is Greatly Improved**

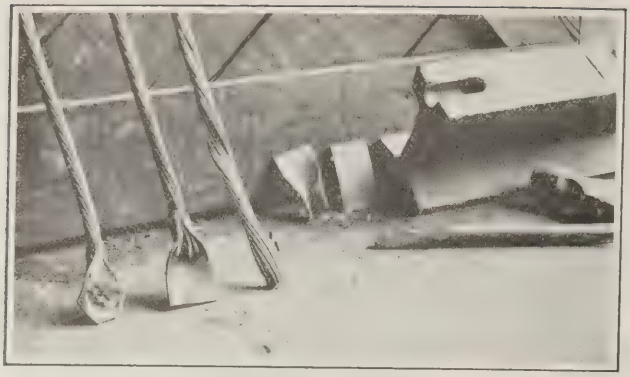
At the Island Creek mines trouble was caused by the burning of power-stud contacts on controllers. An extra finger, indicated on the illustration by an arrow, was added to the face plate, to provide a parallel path for the running current and all difficulty was removed.

---

## A Way to Make Bonds At the Mines

During the war we adopted the arc-weld type of rail bond for our mine tracks, but found that we were constantly being delayed in getting the bonds by slow shipment.

After some experimentation we developed our own bond, made from 19-strand 00 copper cable with a steel terminal oxyacetylene welded to the strand. The illustration shows the several steps in the process



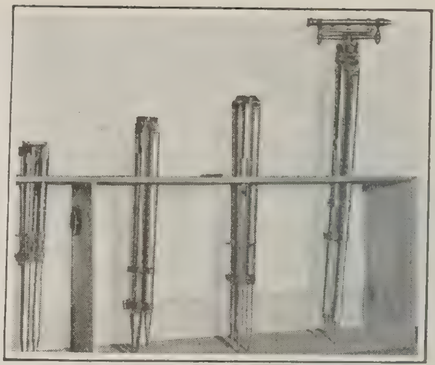
**Home-Made Bonds**

When shipments of material were slow and uncertain this method of making rail bonds was devised. Pieces of iron are bent into shape and then welded to the copper cable by means of an oxyacetylene torch.

of making the bond, together with a somewhat primitive method of forming the terminal. This has since been abandoned for a hand-power press which shapes them more nearly to the finished size.

As we doubted the conductivity of these bonds at first, as compared with the factory product, we made several hundred tests of them with a bond tester. We found that they had the same average conductivity as other bonds. Naturally, a saving in cost has resulted from this work.

R. R. Schellenger,
Electrical Engineer.
Elkhorn Coal Corporation,
Wayland, Ky.



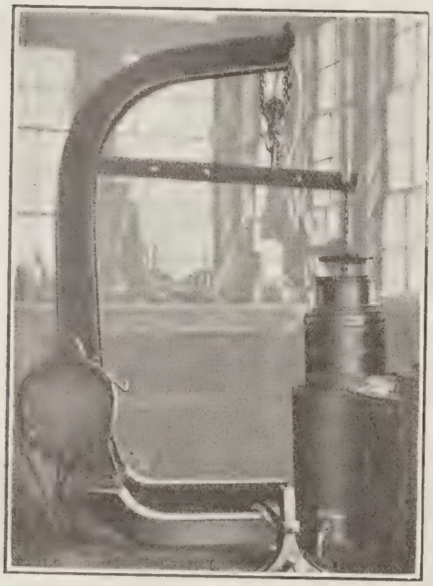
**Rack Safeguards Instruments**

This instrument rack in the engineering department vault of the Fordson Coal Co., at Stone, Ky. is made up of ordinary 1-in. pine lumber 16 in. wide. In the top board, which is 30 in. above the floor, holes are provided for six tripods. These holes are 6 in. in diameter and are spaced on 18-in. centers. C. R. Bourland, chief engineer, believes there is sometimes less risk to an instrument left on its tripod in a suitable rack than to one removed from the tripod at the end of each shift and placed in its case or box, as is the common practice.

---

## Special Jobs Are Handled By Boom on Crane

Use of a portable floor crane for certain jobs of shop work is impractical because the bed of the machine extends several inches beyond the center line of the lift. The usefulness of such a crane for certain jobs, can be much increased by adding a boom such as that shown in the accompanying illustration. This photograph was taken in the central repair shop of the Fordson Coal Co. at Stone, Ky.



**Holds Armature Out Over Tank**

For special jobs where it is necessary to reach beyond the bed of a floor crane, a boom can be attached, but too much weight on the end of the boom will tip the crane. Use of such a device therefore, must be accompanied by the exercise of reasonable discretion.

In this case a 2-ton portable floor crane is being used to dip an armature. The boom is a $\frac{3}{4}$x4-in. bar having a 14-in. extension beyond the hook of the crane. This extra distance brings the armature above the center of the tank when the front wheels of the crane bed are against its sides.

Like a floor crane itself, the boom is not a foolproof device. With it, only a certain fraction of the rated capacity of the crane can be lifted. The weight which can be handled without tipping the crane depends on the length of the extension beyond the hook.

---

## Grouping of Supply Records Simplifies Work

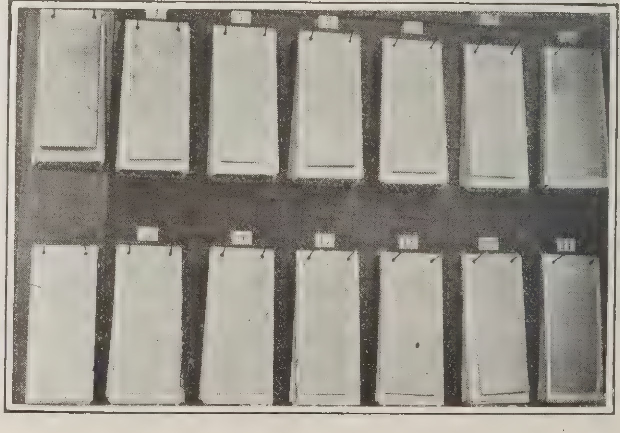
It is only in unusual cases that a chief electrician in charge of maintenance of coal mining equipment has a clerk to take care of his files and records. Therefore, either because of lack of time or lack of experience in clerical work, he does not use "system" to any great extent. There are, however, ways of systematizing the work without involving burdensome clerical work.

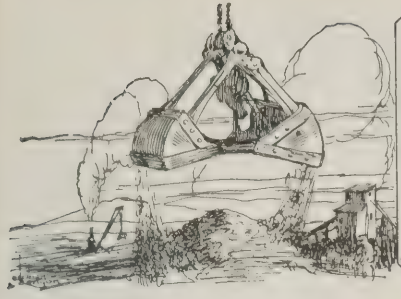
An example is the method which a chief electrician at a coal mining company's operation in West Virginia uses to keep record of repair material taken from the warehouse to the mines. Mounted on the wall near his desk in the electric shop he has a board on which copies of material orders are filed. A pair of finishing nails, a card bearing the mine number, and a heavy piece of cardboard, make up the file for each mine.

When orders are written repair parts for one mine only are listed on a single sheet. The carbon copies are then filed on the board in their proper places. The heavy pieces of cardboard placed on top of each file keep the sheets from blowing off. The orders, being filed consecutively as regards dates, it is quite easy for the chief electrician to "check up" on the quantity and character of material used at a certain mine during any period.

**Easy Filing System**

Carbon copies of all orders for repair-part material are properly grouped here so that it is a simple matter to learn how much and what kind of material each mine is using.





# Production And the Market

## General Softness Descends on Coal Market: Rumors Give Place to Action

Acceptance by John L. Lewis, United Mine Workers president, of Governor Pinchot's proposal to end the hard-coal strike and the operators' flat refusal to consider the Governor's plan were easily the outstanding events of the last week. President Coolidge has not as yet replied to the Lewis letter of Nov. 22 asking federal intervention in the soft-coal situation and reiterating his more or less thinly veiled threat of a general strike, but as Congress will convene next week Mr. Coolidge's message may embody the answer, to say nothing of the probable action of the legislative body itself.

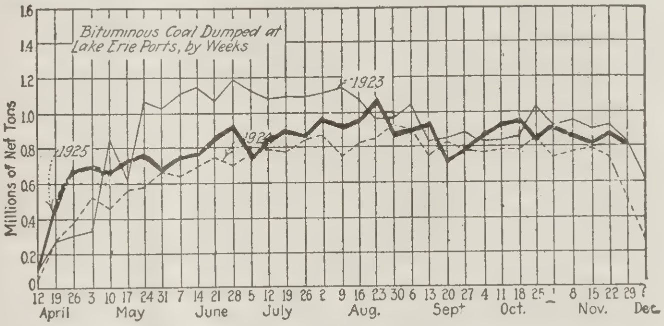
Soft-coal production continues at almost record-breaking levels, and the market is absorbing the tonnage remarkably well, though prices, it is true, show a softening tendency under the influence of unseasonably mild weather and the virtual end of lake shipping, which always is an unsettling influence. Consumers in general are buying only for current needs and as a result some inducement sometimes is necessary to avoid demurrage charges, but even so "no bills" are in evidence.

Scarcely a field or division of the trade escaped the continued reaction, West Virginia smokeless, Kentucky, Indiana, Illinois, southern and eastern Ohio, and central Pennsylvania coals of all sizes and qualities partaking in the decline. Business is fairly steady in the New York and Philadelphia markets, but in New England weak spots have appeared in the steam trade due to an absence of spot industrial demand. Liberal shipments off the Northwestern docks at Duluth and Superior are reported. The activity at Birmingham is keeping producers on the jump to keep up with requirements.

Transportation difficulties have been pretty well cleared up on the Louisville & Nashville R.R. Movement of coal through the Cincinnati gateway last week totaled 14,318 carloads, which was 119 less than the previous week but 419 more than in the corresponding week of last year.

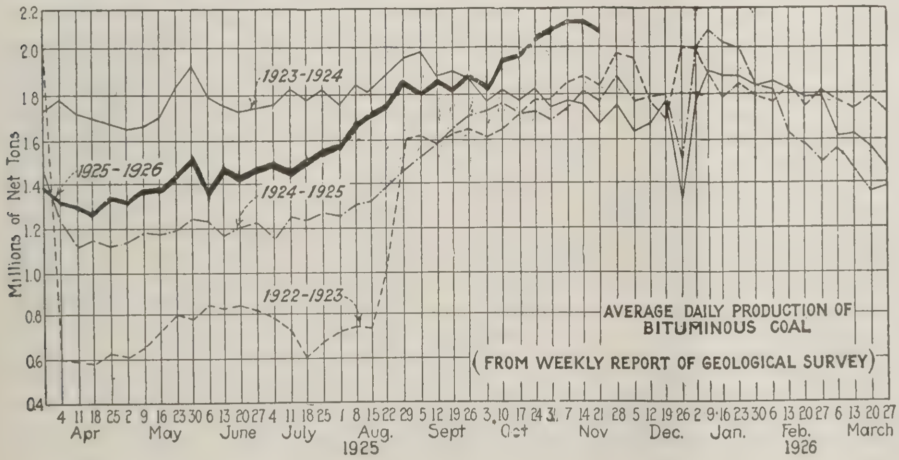
The inactive but expectant attitude of anthracite consumers has served to put a further crimp in the demand for coke, so that prices continued to show a declining tendency and output also has fallen off.

Output of bituminous coal in the week ended Nov. 21 is estimated by the Bureau of Mines at 12,624,000 net tons, compared with 12,167,000 tons in the previous week. Anthracite production in the week ended Nov. 21 was 46,000 tons, against 32,000 tons the week before.



*Coal Age* Index of spot prices of bituminous coal on Nov. 30 stood at 187, the corresponding price being $2.26, compared with 192 and $2.32 on Nov. 23.

Dumpings of coal at Lake Erie ports during the week ended Nov. 29, according to the Ore & Coal Exchange, were: Cargo, 769,446 net tons; steamship fuel, 35,978 tons—a total of 805,424 net tons, compared with 862,130 tons in the preceding week. Hampton Roads dumpings in the week ended Nov. 26 totaled 483,234 net tons, against 332,720 tons in the previous week.



### Estimates of Production

(Net Tons)

| BITUMINOUS | 1924 | 1925 |
|---|---|---|
| Nov. 7 | 9,695,000 | 12,171,000 |
| Nov. 14 | 10,466,000 | 12,167,000 |
| Nov. 21 (*b*) | 10,910,000 | 12,624,000 |
| Daily average | 1,818,000 | 2,104,000 |
| Cal. yr. to date | (*c*) 423,265,000 | 456,339,000 |
| Daily av. to date | 1,544,000 | 1,659,000 |
| ANTHRACITE | | |
| Nov. 7 | 1,592,000 | 28,000 |
| Nov. 14 | 1,674,000 | 32,000 |
| Nov. 21 | 1,827,000 | 46,000 |
| Cal. yr. to date | (*c*) 80,747,000 | 61,847,000 |
| COKE | | |
| Nov. 14 (*a*) | 150,000 | 295,000 |
| Nov. 21 (*b*) | 158,000 | 283,000 |
| Cal. yr. to date | (*c*) 8,531,000 | 9,064,000 |

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Midwest Buys Only for Current Needs

In the Chicago and Middle Western market the general public continues to buy only for current needs, thus forcing most retailers to pursue the same tactics. This situation also prevails in the steam market, where there is but little activity. Nobody pays much attention to the anthracite shortage, as those who have used up their current supply of hard coal and find they cannot procure any more have turned to coke and smokeless coals with satisfaction.

The domestic market is not so good this week; the weather has been fairly warm and the call for coal has been unusually soft. Franklin County operators, who raised the price of 6-in. lump to $3.50 Nov. 18, have booked but little business on this new basis. It is only fair to say, however, that they gave their trade plenty of advance notice and consequently those retailers who were in the market bought at $3.25 and so are taken care of for the time being.

Prices on smokeless domestic coals have fallen off sharply, as some good prepared smokeless lump has been offered as low as $4.25 in the Chicago market. Egg continues to command a better price than lump, no doubt on account of the demand for egg from the East. West Virginia high-volatile coals also suffered a little decline, principally because the market in the East has not come up to expectations. The result is that plenty of good high volatile from West Virginia can be bought at this writing at $2.75@$3.25 for block and $2.40@$2.75 for egg.

West Kentucky domestic coals are moving in increased volume into Iowa, where the demand seems to have settled down for a cheap coal of reasonably satisfactory quality.

The steam market was just a little better this week, principally on account of the falling off in the demand for domestic sizes. Purchasing agents are buying only for current needs and are not in the least bit disturbed over rumors of strikes and walkouts.

In southern Illinois the demand for domestic is easing up, although lump is moving fairly well; egg and nut are somewhat hard to move, however, and some mines have even a few lump "no bills." Steam at the shaft mines also is slow and these mines are just about getting by with from three to five days a week. Movement of railroad tonnage from these mines in the last week has been fairly good, but there has been a slight car shortage at some points. Strip mines are getting full working time and an apparently ready market, although prices are uncertain. One thing that seems to be hurting shaft-mine steam sizes is the fact that the strip mines can crush better coal and undersell the shaft mines.

In the Duquoin and Jackson County field somewhat similar conditions exist both as to shaft mines and strip mines and working time is about four days a week. There has been no change in prices in southern Illinois with the excep-

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Nov. 30 | Nov. 23 | Nov. 16 | Dec. 1 |
| Index | 187 | 192 | 190 | 171 |
| Weighted average price | $2.26 | $2.32 | $2.30 | $2.07 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and, second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

tion that egg went to $3.50 and 2x3-in. nut to $3.25 on the circular of some of the shippers, but someone must not be holding to the circular as much coal can be bought below the circular price. In the Mt. Olive field conditions apparently are good. The movement of domestic shows improvement, steam is doing better and railroad tonnage is moving well. Mines are working pretty nearly full time. In the Standard field it is the same old story of selling it at about cost and the mines are getting three to four days a week—sometimes five where they have contracts. Railroad tonnage is fairly good. All mines have "no bills" every night and only by strenuous work is the coal moved.

Domestic business at St. Louis is fairly good, especially for middle grade and Standard coals, but there is no unusual demand. Illinois high grade, which has been in good demand, is due for a slump, as Kentucky and Indiana coals are now coming in, on account of the price. Generally all over the field in the last week there has been a better movement of western Kentucky coal, which comes into St. Louis at about $2.25 f.o.b. mine with a $1.73 freight rate as against Carterville at $3.50 f.o.b. mine with a $1.38 freight rate, and western Kentucky gives unusual satisfaction. Country domestic is not good inasmuch as it is a weather proposition. Locally anthracite and smokeless are slow. Coke is fairly active. Country steam is fairly good. Local carload is about equal to the demand at this season and wagonload shows improvement.

### Kentucky a Shade Weaker

The Kentucky coal market is a shade weaker. There has been some shading of prices over the week, due in part to a considerable let-up in Lake movement and mild weather over the Central states. A considerable tonnage in the Hazard and Elkhorn fields hasn't much of a market now that the bulk of the lake movement is over. Some of this is reported as offered considerably under the usually quoted market, block being obtainable as low as $2.75; some lump at $2.50 and some egg at $2.25. Most quotations on good grades of Harlan, Hazard and Elkhorn 4-in. coals are around $3.25@$3.75, with some of the specialty coals still quoted at $4@$4.50. Egg and 2-in. lump are weaker, however, at around $2.50@$2.80 in some instances, as these sizes are generally in good movement to the lakes.

Screenings in eastern Kentucky are just a shade weaker, at $1.20@$1.50. Eastern mine-run is firm at $1.50@$1.75. In western Kentucky the market is very steady with block at $2@$2.25; lump, $1.75@$2; egg, $1.35@$1.50; mine-run, $1.25@$1.50; screenings, pea and slack, 65c@80c.; 2-in. nut and slack, 80c.@95c., with some at $1.

There are now some "no bills" in both fields, and not much complaint is being heard just now about car shortage. Jobbers report that instead of having to hustle to find coal they are having plenty of it offered to them.

### Northwest Still Busy

Dock operators at Duluth and Superior are still making liberal shipments, though the tonnage is much less than in late October. Industrial plants have been the best buyers of steam coal in the last ten days, though some of the iron-mining companies and utilities have been making contracts.

Retailers' supplies are running low. Demand for Pocahontas and other smokeless substitutes for anthracite is the feature, but stocks of these coals on the docks are ample so that former anthracite consumers are not worrying over the probability that hard coal stocks will be practically cleaned up by the middle of January.

In the face of the heavy demand the docks are quoting Pocahontas nut and stove at $8.50; lump and egg, $9; mine-run, $5.25@$5.50; screenings, $4.25. Three of the docks have received cargo shipments of prepared sizes of Pocahontas and have thus been able to fill orders promptly but plants that have been forced to screen mine-run have found their facilities for handling prepared-size orders inadequate. Other coals are being held exactly where they have stood since early last summer and no changes are looked for in the near future.

Bituminous coal is still moving this way in good volume from the East, twenty-three cargoes having been unloaded at the docks last week and nineteen cargoes were reported en route. Supplies on hand are about 5,500,000 tons, of which around 2,000,000 tons belongs to railroads.

Milwaukee coal-dock managers report a quiet trade, with demand fluctuating with the weather. Consumers are wrestling with the fuel situation without loud complaint. The domestic turn from anthracite because of its absence is largely to Pocahontas of nut size, but there also is a noticeable demand for West Virginia and Kentucky bituminous coal. The weather continues sharp for the season, and household furnaces are going almost at winter gait. In November up to the 27th Milwaukee received by cargo 379,130 tons of bituminous coal. Prices are steady.

### Kansas Catching Up on Orders

After more than a week of mild weather, operators in the Southwest have cut down their unfilled orders for Kansas lump to three or four days, but so responsive is the market to weather changes this season that only a few days of freezing temperature would throw the mines back two or three weeks on deliveries. Nut and mine-run production is just about equal to the demand, while screenings are easy, though no surplus is reported in the field. Owing partly to railroads using more shovel coal this year than formerly the production of shaft screenings is lighter than in other years.

In Arkansas, also, there has been a slackening of demand because of the weather, with an increased production as new mines have opened. Arkansas semi-anthracite lump is quoted at $6@$6.50; mine-run, $2.75@$3.50; screenings $2.25.

In Colorado the demand for domestic coal shows no abatement and prices that compare favorably with the war-time level continue to be maintained. As the labor situation is improving and there are no transportation difficulties the trade is optimistic over the situation.

Operators and dealers in Utah complain that business is not as good as it ought to be at this season of the year. Demand for coal for heating purposes is better than it was, but with the exception of a few cold snaps which brought rush orders for a day or two, there has not been any weather to make a heavy and sustained demand. The call for steam coal is about normal. The car situation is good, prices remain steady, and there is no grade of coal on the market just now that is moving slower than the others.

### Spot Tendency at Cincinnati Is Soft

Smokeless distributors in Cincinnati who issue a monthly circular name $5@$5.50 as the December price for lump and egg coal. This is in the face of the unsettling effect of the closing of the lakes. The spot market tendency is toward softness. Some New Rivers sold down to $4.75. Mine-run is fairly firm with the general average at $2.50. Some small sales have been made at $2.25, but these mostly were for loads that had to be moved. Screenings hold up well, considering adverse market conditions, the range being $1.85@$2.

High-volatile domestic sizes have been struggling with a lull, mostly caused by too rapid stocking by retailers and mild weather. Some Kentucky coal has been offered at $3 for block, the first time for weeks. West Virginia producers name a $2.75 price. From this the quotations range up to $3.25 for ordinary stuff and $4.25 for specialized domestic coals. Egg sizings average around $2.25, a drop of 50c. in the week. Mine-run is in better shape; gas, byproduct and steam holding their own. The surprise of the market is the way that slack holds to its price.

Car supplies on the Louisville & Nashville are better and the movement easier. There is practically a clear line between Cincinnati and the lower assembly yards. Total movement through the gateways of the Cincinnati district last week was 14,318 loads, a decrease of 119 cars as compared with the previous week but an increase of 419 cars over last year. River business continues at its usual seasonal gait.

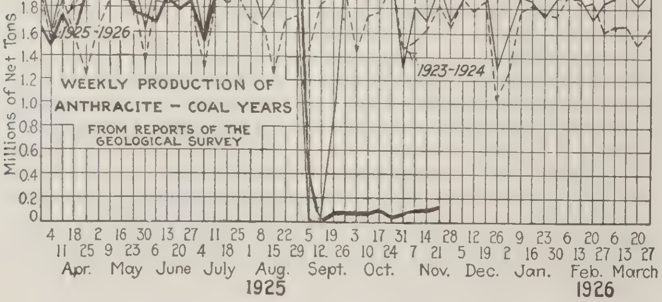
Softness in domestic grades continues in Columbus, due largely to warm weather. Dealers are cancelling some orders placed for shipment late in November and early in December. Prices at the mines have softened to a certain extent, especially on smokeless and Ohio grades. Some splints are being offered at less than the usual prices also. Distress coal is having a bad effect on quotations. Retail prices have not declined as yet as dealers are still rather busy making deliveries on orders previously booked. Smokeless grades are not selling as briskly as formerly as the spread between Pocahontas and splints is too great for consumers and many former smokeless users are content to buy high-grade splints.

Dullness characterizes the steam trade in every way. Users are buying mostly for current needs, as reserves are generally good. Production in the southern Ohio field continues at about 30 per cent of capacity.

In eastern Ohio, coal demand, both domestic and steam, and also for screenings, which were strong a week ago, has subsided somewhat and seems to be pursuing a rather easy gait, with the result that spot prices during the week have softened all along the line 5 to 15c. per ton.

In the week ended Nov. 21 the eastern Ohio output was 356,000 tons, the largest for any week of this year.

Total coal from all districts cleared over the lower lake docks up to Nov. 23 was 25,018,776 tons, as compared with 22,001,161 tons for the same period last year and 28,995,709 tons in 1923. Today there still remain some 8,000 cars under load at the lower docks awaiting clearance, and there are approximately 2,000 cars of lake coal in transit from the mines. Shipping in this trade from the mines ended Nov. 28.



### Eastern Demand Still Absent at Pittsburgh

The trade is distinctly disappointed over the course of the Pittsburgh coal market in the past two weeks, as there has been no revival in the Eastern demand. Demand from the restricted area the Pittsburgh district has been serving for the past year and a half has kept up quite well. Industries are consuming more than formerly and buying of domestic coal has been increasing somewhat in the past few weeks, being about normal for the time of year.

There still is no definite market price for egg coal, sellers simply getting what they can. In the past week there seem to have been some small lot sales at over $3, but in general the price is much less. Three-inch lump is going generally at $3.25@$3.50, against $3.75@$4 at the peak. Other prices are substantially unchanged.

Interest in Buffalo still centers on household trade. The ordinary bituminous trade is dull and it promises to be worse soon, unless something unexpected comes up. Prices are low and they promise to stay there. This is shown by the increase of coal standing on track unsold and by the appearance during the past few days of domestic coke, mostly egg size, that cannot find a buyer.

### Soft Spots Appear in New England

Soft spots in steam coal have again appeared in New England. Fresh accumulations at Hampton Roads with much lighter demand all-rail have together forced the agencies to consider lower prices than were thought possible a week ago. Rumors of an approaching anthracite settlement also have played their part, but the main factor is the almost entire absence of any spot demand from industries. The latter have already taken on reserves sufficient for months ahead, and aside from the steady movement coastwise of tonnage on contract the volume of coal coming forward on contract is by no means heavy.

There is a decided lull in the market for screened sizes all-rail, especially from the smokeless fields. It is becoming quite evident that the New England public is not much inclined to change habits and put in quantities of bituminous in advance of actual necessity. In most communities, especially in or near the large cities, it is still possible to be accommodated with anthracite in small lots. Pea and No. 1 buckwheat are available in many places, and in Boston, Portland, Providence, New Bedford and other cities high grade Welsh anthracite is to be had in moderate amounts. For all these reasons the retail dealers are shy of buying more lump and egg from soft-coal operators until the public relieves them of what they have on hand at high prices. In consequence, what feeble demand there is for low-volatile screened is being more and more restricted to the quality grades in central Pennsylvania where the lowest through tariff applies.

As yet there has been no reduction from the $6.50 level for Pocahontas and New River run of mine per gross ton on cars Boston and Providence for inland delivery. Practically all the distribution business is now in the hands of factors with ample storage facilities, and only when coal is forced on them by accumulations at the Virginia terminals are they at all pressed to move coal along to the consumer.

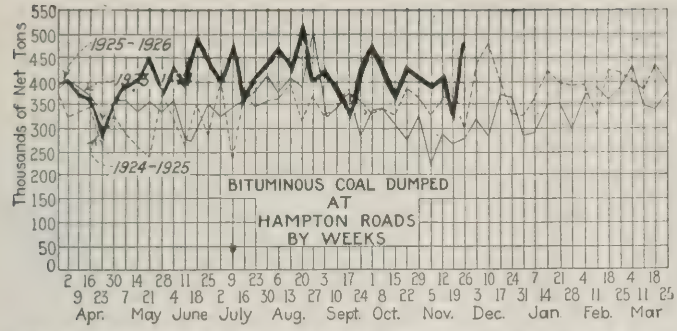
Run of mine from central Pennsylvania all-rail also is in the doldrums. Prices are off slightly on the part of those actively seeking business, and inquiry in this territory is confined to the narrow area that is not open to competition from smokeless coals via tidewater discharging ports.

### Steady Trade at New York

John L. Lewis' letter to President Coolidge made no impression on soft-coal consumers in the New York area. Most industrial users have good-sized reserves for emergency purposes and they are taking in a fair volume.

Movement of mine-run grades has been steady and up to normal requirements. No additional strength, certainly not in permanent prices, was noted during the week. Some of the maximum prices for the various pools are a trifle above last week's quotations but most of the coal went at the minimum figures.

Dealers in screened coals are looking for a sharp upward turn soon. At present the market is quiet. West Virginia



coals are quoted at $3.25@$4 and Pennsylvania coals at $4@$5. The latter are finding a ready market.

New River and Pocahontas lump is taking well in this territory, the quotations ranging around $4.65, and for egg at $4.75@$4.80. Fair-sized all-rail shipments of these coals have been made to Long Island points and are giving entire satisfaction.

Demand for soft coal at Philadelphia goes along quietly, but the business situation of all producers is far stronger than at this time last year as attested by increased tonnage and much better prices. Most of the contract users are coming along for their full quotas and in addition those buying on the market are increasing their orders. There also is the always present railway fuel business. These factors are holding prices to their present level on the spot market in the face of the possibility of a loss of tonnage if the hard-coal situation is cleared up.

Demand for soft coal at Baltimore continues moderate for prepared sizes while the rest of the soft coal market remains rather flat. Prices, it is true, are a little stronger than a week or so ago, and more nearly approximate quotations that came shortly after the start of the anthracite strike. No further export movement is recorded from this point and immediate prospects along the line are negligible.

At Birmingham the coal market continues very active. All grades of steam are in good demand, and coking coals are especially strong and the supply hardly equal to requirements. Washed steam of the better grades also is being bought up heavily, some of the leading producers having turned down considerable business during the past week. All consuming interests are taking additional coal with a view of building up a reserve for the holidays, and current consumption by industrials, railroads and utilities is abnormally heavy. Producers are hardly able to meet the demand for bunker fuel to supply shipping interests at Gulf ports. Export shipments to Cuban points are reported slow, due to inability to obtain bottoms, many of the vessels plying in this trade now being engaged in relieving traffic conditions in Florida.

Mines are very well supplied with domestic orders and current production is being promptly moved. Intermittent cold spells are keeping retailers fairly busy. The better grades have the favored call, but on account of the limited supply the market for the medium and lower qualities is thereby improved.

Quotations on steam and domestic sizes are without material change from a week ago. Car shortage has eased up, but complaints of labor shortage are still being reported—especially common labor.

Coke buying for foreign shipment has eased up a little due to lack of cold weather in the North and West. Foundry coke is in good demand locally at $6.50 per ton for spot. Egg and nut sizes range $4.75@$5.50, with about the same range for gas coke.

## Peace Talk Depresses Hard-Coal Market

Reports of peace talk in the anthracite field last week had a depressing effect on the hard-coal situation at New York, and as on previous occasions resulted in cancellations of some orders for substitutes. Consumers continue to hesitate about putting in substitute fuel, and meanwhile users having anthracite in their cellars are using it.

A couple of cargoes of British anthracite arrived in the harbor during the week, one of which was without consignment. Its owners, however, did not expect any difficulty in disposing of it.

Movement of free independent pea and buckwheat coals has slowed up. Wholesale dealers report few sales and quotations for pea range $16.25@$17 alongside. Buckwheat was quoted at $8@$8.50, also alongside. It was said there were a few small lots of egg, stove and chestnut coals offered, but no sales were reported. The larger companies continue to hold some buckwheat coal, which they are doling out on contracts.

Coke is moving steadily. Connellsville furnace coke was quoted at $4.50@$5, with foundry product at $6@$6.50. Egg was quoted at $7@$7.25 and nut at $7.50@$8.

The Philadelphia market is extremely quiet, as the temperature has been mild and rumors of the possibility of an early settlement of the strike have held back business. Coke is the fuel that leads, yet even sales of this have been meager of late. Plenty of beehive coke can be had at $6@$6.50, with byproduct selling at $7@$9. There seems to have been a grand rush to get in the beehive coke game and many ovens which have not operated for years are reported to be getting under way. This increased production has had much to do with the big drop in the price of this fuel. In addition to this coke has been badly marketed with retailers.

A stray car or two of anthracite pea and some shipments of buckwheat have arrived lately, but so far as the general market is concerned these sizes no longer figure, and with them anthracite is pretty much removed as a factor until mining is resumed.

There is no hard-coal situation at Baltimore, as dealers continue to sell prepared sizes of bituminous to former anthracite customers. There is some question in the minds of the local hard-coal dealers as to whether history will repeat itself, and the new users of bituminous return to hard coal when supplies of that commodity are resumed. The answer may be in the future price of anthracite as compared with that of the future price of prepared sizes of bituminous.

When it was thought by some that a settlement of the strike was near the demand at Buffalo for bituminous coal for domestic use fell off so that it had to be offered as low as $3 at the mines for egg size, with no takers, though it had of late sold as high as $4 or even more. Connellsville coke also fell rapidly, as consumers had found it so high that they preferred anthracite if it could be had. Local byproduct cokes have not fluctuated so much, the steadiness being increased by the holding of the product of one company at $7.50 at the curb, while others were sometimes up to $14. Prices are mostly dependent on the prospect of settling the strike.

## Connellsville Coke Market Declines Again

Eastern buying of coke at Connellsville has not revived, which means a further decline in market prices, for production had greatly increased on account of current sales, most of which were spot or for shipment within a week. Coke has accumulated on track, but not a great deal, for, in view of heavy transportation requirements, railroads will not allow cars to be used for storage purposes.

Thus production had a momentum and purchases have not sustained the market. While the *Courier* report shows a slight increase for last week in merchant oven production, the fundamental trend has been the other way since the preceding week had been restricted by labor troubles, now practically ended.

While the report of eight days ago noted offerings of furnace coke going the rounds at $5 in the last couple of days several operators have been offering coke at $4, and meeting somewhat limited response. It might be expected that the blast furnacemen, whose contracts run out Dec. 31, might pick up some of this coke to use afterward, but they show little interest.

Foundry coke also has weakened from heavier production. Some operators switched from 48 to 72-hour burning to reduce tonnage, and it is now quotable at $5@$6 on actual offerings.

## Car Loadings, Surplusages and Shortages

# Foreign Market And Export News

## Broader Inquiry in British Coal Market; French Orders Scarce

Inquiries in the British coal market are steadily expanding, but the progressive movement is partially checked by the scarcity of orders from France, the low level of exchange stimulating the sale of native coal to the exclusion of imported supplies. Despite this handicap, which is exceedingly serious to Wales, business is more evenly distributed among the different grades, and further compensation is provided in a consistent expansion in home demand and the development of forward inquiry.

There is a pause in buying from the United States and Canadian business lags on the closing of river navigation. To the former 130,000 tons has been booked, the bulk which has yet to be shipped. South American orders are much more numerous, and in addition to a contract of 75,000 tons (two-thirds best large, one-third best small) for Lloyd Brasileiro other period business is offering. Italy is buying on a fair basis. Coaling depots are more active, and there is a brisk inquiry from Spain and Portugal.

The Newcastle-on-Tyne market improved again during the week, and in every section there was quite a brisk demand for fuel at current prices running practically till the end of the year. The coke market, too, maintained the improved tone of last week, and there has been quite a revival in that business following a better outlook in the iron trade. Contract business was not on a large scale and was mainly for gas coals, but the prices paid for over the year indicate a maintenance of current quotations.

Output by British collieries during the week ended Nov. 14, according to a special cable to *Coal Age*, totaled 4,880,000 gross tons, compared with 4,790,000 tons in the previous week.

---

## Bookings Satisfactory in French Coal Market

Although the present state of industry is not of a nature to provoke a very strong demand for fuels in the French coal market the French mines are filling their order books in a satisfactory manner, due to the depreciation of the franc. Calls are coming from consumers who under ordinary circumstances buy abroad, British coals suffering most. The State Railways have been authorized to ask for prices in Belgium on briquets to be delivered at ports of the West, those from across the Channel being too costly.

Demand for choice domestic coals has been light, which has enabled dealers to restock their yards in preparation for winter.

Receipt of indemnity fuels from the Ruhr during the first twenty-four days of October included 330,500 tons of coal, 185,200 tons of coke and 23,900 tons of lignite briquets. During the first nine days of November the O. R. C. A. received from the Ruhr 54,321 tons of indemnity coke.

French fuel output during September, 1925, consisted of 3,996,863 metric tons of coal; 83,804 tons of lignite; 262,564 tons of coke and 343,771 tons of patent fuel. Total production during the first nine months of 1925 was: coal, 35,591,622 metric tons; coke, 2,234,116 tons; patent fuel, 2,619,711 tons, compared with 33,325,931, 1,928,415 and 2,391,011 tons, respectively, in the corresponding period of 1924.

## Belgian Trade Tendency Weaker

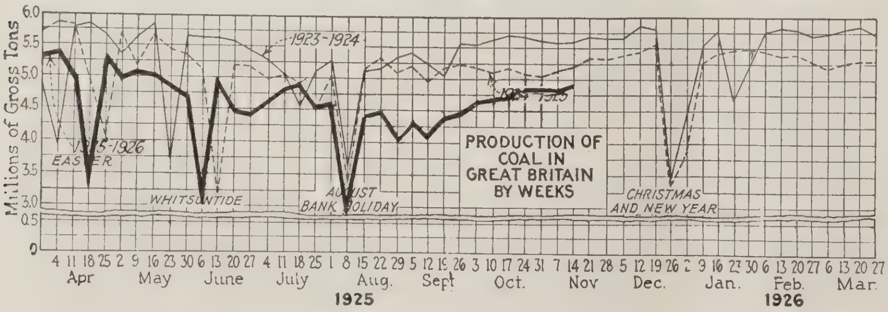
The price tendency in the Belgian coal market is again weaker. Demand is extremely modest and is inclined to decrease because of the keenness of French competition, aided by the depreciation of the French franc. British competition, on its side, has not decreased any more than the German and the Dutch. In the Borinage district in particular the crisis is felt and the reign of concessions, far from diminishing, is more in evidence than ever.

In industrial grades bituminous coals and coking smalls are most neglected; semi-bituminous coals are moving better, as are smalls for making cement and lime. Movement of lean duffs is still nil.

The tendency in domestic coals remains firm, and as cold weather has returned the outlook is favorable.

Briquets, in spite of the effect of the high cost of pitch, are in slightly improved demand, especially on the part of the Belgian State. The demand for coke also is a little stronger, at 125 fr. for metallurgical quality.

Prices as of Nov. 1, 1925, compared with those of Oct. 1 show only these differences: 3 fr. decrease on washed semi-bituminous duffs and 2 fr. on dry peas.



## Further Weakness Appears At Hampton Roads

Business at Hampton Roads was comparatively slow last week, with prices showing a tendency to weaken. Quotations for domestic coal were holding their own at $6.50@$7 at the mines, and the retail price showed no further incline above the scale of $12.50@$13 fixed several weeks ago.

Foreign business showed the biggest drop, though neither coastwise nor bunker trade was up to normal. Shippers held the new movement of coal to the North by rail as responsible for a comparative lack of interest in the coastwise trade.

# News Items From Field and Trade

## ARKANSAS

The Central City Coal Co., which has been operating between Branch and Charleston, has moved to Prairie View and has taken the contract for the Scranton Coal Co. to strip anthracite coal.

## COLORADO

The state coal mine inspector's report, just released, shows October's production was 1,144,960 tons, contrasted with 1,050,805 tons in the same month a year ago. The number of men employed was 12,136 compared with 12,608 a year ago for the same month. The number of days worked per mine for October, 1925, was 142.1 compared with 148.1 in same period a year ago. The increases in production occurred in Routt and Las Animas counties, the other districts just about holding their own.

## ILLINOIS

The itinerary of the Illinois Miners' Examining Board has been announced for this month as follows: Belleville, Courthouse, Dec. 7; Christopher, Miners' Hall, Dec. 8; Harrisburg, Rom Club, Dec. 9; Duquoin, Miners' Hall, Dec. 11; Centralia, Miners' Hall, Dec. 12; Staunton, Labor Temple, Dec. 14; Springfield, State House, Dec. 15; Taylorville, Courthouse, Dec. 16; Danville, Courthouse, Dec. 17; LaSalle, City Hall, Dec. 18, and Peoria, Courthouse Dec. 19.

No. 1 mine of the Superior Coal Co., Gillespie, broke its record Oct. 29 for a day's hoist, when the mine produced 5,041 tons of coal in 1,626 dumps. Several years ago the rumor was current that No. 1 mine was fast being worked out, but since that time the mine has broken a number of records.

After being shut down for about a year and a half the St. Ellen mine, at O'Fallon, is again in operation. The mine gives work to 450 miners. It is reported that the Prairie mine, also at O'Fallon, which has been closed for many months, may also reopen.

## INDIANA

The Pike County Collieries Co., owning strip mines in the southern part of Pike County, resumed operations Nov. 18 after a week spent in the hands of a receiver, Fred I. Conyers. Contested pay checks given miners at the time the receivership took place have all been redeemed and miners have been paid for their services. The company operates three giant shovels, employs 250 men, and owns real estate and equipment in Pike County valued at $1,000,000. The company has a production of from 60 to 80 cars of coal a day, requiring two trains to handle.

The tipple of the Somerville mine, wrecked by fire several weeks ago, is being replaced by a temporary wooden structure, which will ultimately give way to a steel structure. Operations at the mine are expected to be resumed within six weeks.

## IOWA

An agreement has been reached between Budget Director Hogue and members of the board of mine examiners by which the board will hold only six meetings a year and with only three of the five members in attendance, in order to reduce expenses. This is the result of findings of F. H. Paul, accountant, which included an assertion that the board was likely to exceed its biennial appropriation before the two-year period expired. The recent Legislature was asked by Mr. Hogue to reduce the membership of the board from five to three and fix its appropriation at $2,000. The appropriation, supplanting a system by which the board's allowance was unlimited and under which it spent about $4,000 annually, was provided, but the law was otherwise unchanged.

## KANSAS

James Price and Joe Lafayette, both of Pittsburg, have leased from J. S. Patton, of Frontenac, the old Hamilton Mine No. 7, known as Radley No. 7, near Radley, and expect to have it in operation early in December. The mine has been idle several months. It will employ seventy-five men.

The Crowe Coal Co. on Nov. 17 reopened its mine No. 21, near Croweburg, after several months of idleness. The mine employs from 200 to 250 men.

At the suggestion of Mayor C. Mart Montee, of Pittsburg, the Pittsburg Chamber of Commerce again this year is sending out small bags of southeastern Kansas coal to all mayors of the state. The bags carry the admonition imprinted on them, "Use Kansas Coal."

James Sherwood, Kansas state mine inspector, recently announced that one hundred more mines are operating now in Kansas than at this time last year. All but two of the district's larger mines are working. Central Coal & Coke Co.'s No. 50, closed since 1921, and the Sheridan Coal Co.'s No. 20, alone of this class are idle. The Western Coal & Mining Co. has one new mine in operation, and another down to a depth of 250 ft.

The Lone Star Coal Co. has started the erection of a shovel on coal land it controls west of Pittsburg and expects to be mining coal within one or two months. The Joplin & Pittsburg Railway Co. will build an extension of its track to the mine. J. J. Nesch and R. G. Nesch, both of Pittsburg, two of the men interested in the new company, estimate their land contains sufficient coal for ten years' operation.

Hoisting at the Chapon & Westerlin Coal Co. mine near Chicopee, began Nov. 23. A new tipple recently was built to replace the one destroyed during the strike of 1921, since which time the mine had been idle. The mine employs 100 men. Its product is being handled by the Central Coal & Coke Co.

## KENTUCKY

From Madisonville it is reported that the Federal Coal Co., of Indianapolis, has leased coal rights on 170 acres of coal land from T. M. Slaton, living near Madisonville. The acreage is on the Central City-Dawson Springs division of the Illinois Central R.R., four miles from Madisonville, where a shaft mine will be installed to mine the No. 9 and also the No. 11 beds.

The eastern Kentucky development along the Virginia border to follow announcement of routes to be used by the Louisville & Nashville R.R. in making connections from the Cumberland Valley and East Kentucky divisions of the road to the Carolina, Clinchfield & Ohio R.R. has been further delayed by application of the Louisville & Nashville R.R. for thirty days' additional time in which to file proposed construction lines for the two connections. This means that the papers will not be filed until about Feb. 1 and that there will be alternate routes included, which will mean some delay before definite routings will be established.

A recent report from southeastern Kentucky was to the effect that a number of the coal operators in the Harlan field were preparing for larger production, the Black Mountain Coal Corporation, at Kenvir, planning erection of fifty more homes and improvement of plant. The Harlan Collieries Co., at Ages, has just completed a string of houses, doubling its housing facilities, and other camps are reported to be enlarging.

It was recently reported from eastern Kentucky that T. C. Vaughan, of Elsiecoal, a manager for the Consolidated Fuel Co., a Pittsburgh company, over a period of several years, had resigned, planning to enter business in one of the mountain towns.

It was reported from Madisonville on Nov. 20 that the body of Tony Chortina, the last of five men killed in an explosion of gas in the Finley Coal Co. mine, had been recovered by workers from the U. S. Bureau of Mines, Evansville (Ind.) division, which sent a car to the scene after the explosion of Nov. 19. Trouble was experienced in reaching three of the bodies, due to fallen slate and fire. Two of the seven men in the mine escaped.

The Consolidation Coal Co., having large mines at Jenkins, McRoberts, Dunham and Burdine, is to start immediately a large improvement campaign including the opening of new mines, extending spur tracks, and building new miners' houses in and around its plants, which will necessitate the expenditure of several hundred thousand dollars.

## MINNESOTA

The Duluth & Iron Range R.R. is rebuilding the pockets section of its coal dock at Two Harbors. The dock is 936 ft. long and has a storage capacity of 100,000 tons. The forty wooden pockets are being replaced by steel ones and the dock is being generally overhauled. The contract for the steel work has been let to the American Bridge Co. at a cost of $110,500. The dock is Mead-Morrison equipped. In addition to handling coal required for mines on the Vermilion range and for its locomotive department the company supplies coal to its employees.

## NEW YORK

The firm of Willard, Sutherland & Co., 8 Bridge St., New York City, will retire from business Dec. 31, next. Le Baron S. Willard will become affiliated with the Berwind, White Coal Mining Co., 1 Broadway, on Jan. 1.

## NORTH DAKOTA

Appeal to the Supreme Court from the decision of the Burleigh County District Court was taken Nov. 21 by the Washburn Lignite Coal Co., in connection with its suit to enjoin the state board of administration from carrying out alleged illegal contracts with competing coal companies. The plaintiff's contention is that the board has illegally awarded contracts to the Republic, Knife River and Lucky Strike coal companies despite the alleged fact that the plaintiff submitted a lower bid. The lower court held that it could not interfere with the discretionary powers of the state board. The board contended that the awards were based on the value of the coal as shown by chemical tests and actual experience and that the coal from the plaintiff's mine tested by the board was less efficient than that from the mines of competing companies.

## OHIO

The Fort Pitt mine of the Central Coal Co., of Pittsburgh, on the Ohio side of the Ohio River opposite Moundsville, W. Va., opened Nov. 30. Approximately 170 miners went to work on the Jacksonville scale. The mine had been closed for a year.

After a one day's trial at Pomeroy, the suit of the Martin Ebersbach Coal Co. against the New Pittsburgh Coal Co. for $550,000, claimed as unpaid balance on the sale of six coal mines in the Pomeroy Bend district two years ago, was stopped by the judge, who asserted the matter was one for the two business firms to adjust outside of court.

The Akron Coal Co. has reopened the Murray Hill mine, at Cambridge after an idleness of several months. The plant employs 250 men.

Tom Bush, who for eighteen years was connected with the coal department of the Chesapeake & Ohio Ry. at Cincinnati, has been advanced to the position of coal agent, with headquarters in the Spitzer Building at Toledo.

Operations in the Pomeroy Bend field have been rather brisk during the past two weeks. As the mines in this field are operating either under the 1917 wage scale or under the co-operative plan, they have a decided advantage over other parts of the southern Ohio field, where the Jacksonville scale prevails. The New Pittsburgh Coal Co. is producing from 1,600 to 1,700 tons daily at three large mines employing 550 men. The mines operated are the Dark Hollow Mine, No. 72; the Syracuse Mine, No. 75, and the Thomas Mine, No. 76. The Forest Run mine, which had been in operation for several months, has been closed temporarily. The Stalter-Essex Coal Co. has two mines in full operation, employing about 350 men. The Blue Stone mine, at Rutland, the tipple of which was destroyed last August, is now running full blast.

Announcement is made that the litigation between the New Pittsburgh Coal Co., of Columbus, and the Peacock Coal Co., of Pomeroy, controlled by the Ebersbach interests, involving about $3,000,000 and a large tract of good coal land, has been dismissed and the case settled out of court.

Nolan Mahan, of the General Coal Co;. John Stirnkorb, of the Hatfield Reliance Coal Co.; Armour A. Sizer, of the Flat Top Fuel Co.; C. R. Moriarty, of the Cabin Creek Consolidated Coal Co.; John Callahan, of the Southern Coal & Coke Co., and J. C. Layne, Jr., of the Man O' War Fuel Co., have been nominated for directors of the Cincinnati Coal Exchange.

The property of the Buckthorn Collieries Co., located in Tuscarawas and Guernsey counties and consisting of 1,400 acres, has been sold by Attorney O. O. Vrooman, of Cleveland, who has been acting as trustee for the property, to a syndicate of Cleveland capitalists. The new company will be known as the Cleveland Collieries Co. and will have general offices in Cleveland. The price paid for the property is $54,900.

## PENNSYLVANIA

At a meeting of the Johnstown Association of Credit Men, Nov. 24, Charles O'Neill, of Altoona, secretary of the Central Pennsylvania Coal Producers' Association, explained that it was freight rates, not labor, that have reduced production of coal in central Pennsylvania. He said that times and things have changed since the war, but the most inflexible thing is the rate sheet of the Northern roads. The cost of carrying coal out of Pennsylvania is still at the war-time peak. Hauling coal 200 miles for 25c. a ton has put Pennsylvania second and West Virginia first. Production in Pennsylvania has fallen from 180,000,000 tons to 100,000,000 tons and West Virginia has grown from less than 100,000,000 tons to 146,000,000 tons.

The month of November is establishing a new high record in the eastbound loaded freight movement over the Pennsylvania R.R. through the Altoona and Hollidaysburg yards. A daily average has been maintained of 3,755 cars. The tonnage will be higher than in October, 1915, when the daily average was 3,560 cars, which was the previous high mark.

Coal production in the Philipsburg region is steadily increasing and nearly all the mines in the region are opening up under the 1917 scale, while a few are operating at a slightly higher rate. A new difficulty now is a scarcity of mine labor. During the early stages of the slump large numbers of miners went into other industries and advertisements for miners failed to bring them back to their former employment.

It has been definitely announced that the Adrian furnace at DuBois will resume operations at an early date, or as soon as necessary repairs, now under way, are completed. One hundred and twenty-five men will be employed. This is a direct result of the resumption of the coal industry.

After experiencing considerable trouble due to sniping and picketing on the part of labor sympathizers, the Bethlehem Mines Corporation finally got production started at the Marianna mines of the company near Bentleyville, on the 1917 scale. Shipments were made last week in small quantity, three cars going out the first day.

Recovery of the coal industry in the Russellton-Curtisville district is seen in the reopening of the Superior Coal Co. mines at Superior after a shutdown of more than 18 months. Mines of the Republic Iron & Steel Co. at Rural Ridge are operating on part time. Installation of a new cage at the Ford Colliery mine No. 3, at Curtisville, is believed to indicate the early opening of that mine. Miners are returning to the Russellton field, and mining villages are exhibiting signs of life after an enforced idleness of nearly two years.

Two hundred and fifty representatives of anthracite companies, public water companies, railroads and industrial corporations and municipal officials have been invited to attend a meeting of the Delaware River Treaty Commission of Pennsylvania to be held in Harrisburgh Dec. 10. The meeting has been called by Dr. Charles H. Miner, Secretary of Health and chairman of the commission, for the purpose of enabling the public to express its views on the proposed treaty, which seeks to apportion the waters of the Delaware River among the municipalities and communities in New York, New Jersey and Pennsylvania which lie in the Delaware River watershed.

Announcement was made last week of the appointment of former Judge John P. Kelly, of Scranton, as general counsel of the Hudson Coal Co. Judge Kelly succeeds James H. Torrey, deceased, who has acted as legal adviser to the company for many years.

The Braznell mine of the Pittsburgh & Lake Erie Coal Co., about two miles from Brownsville, which heretofore has been a union mine, is preparing to resume operations on the 1917 scale. All of the former employees of the plant refused to work and those occupying company houses have been notified to vacate, so that others can be brought in.

## UTAH

An echo of the coal strike in Utah in the spring of 1923 was heard last week when prosecuting attorneys having jurisdiction in Carbon County, where the strike occurred, moved for the dismissal of the charge of murder against several strikers whose cases had been postponed. The men were said to have been implicated in the killing of a deputy sheriff who was helping to guard the mines. A few convictions were obtained following the death of the deputy, but for various reasons all of the men had not been brought to trial. The scattering of witnesses and the difficulty of obtaining convictions were given as reasons for the request for dismissal.

The Sevier Valley Coal Co. has received permission to offer for sale $60,000 worth of stock, the commission not to exceed 20 per cent.

## WASHINGTON

Oil stored for fuel purposes is blamed for a conflagration which wiped out one of the principal blocks in Seattle's Auto Row recently and was brought under control only after it had done damage aggregating $1,000,000. Many garages and service stations save old crankcase oil and use it for heating purposes. Several barrels of this reclaimed oil had been stored in the basement of one of the automobile service houses. The blaze is said to have started by spontaneous combustion. Three hundred motor cars and 75,000 tires were lost in the fire.

The Bellingham Coal Mines' new 18 per cent slope, one of the longest mine slopes in the United States, began operating Nov. 16. The slope, which is nearly 2,000 ft. long, will serve the fourth and lower levels. It will be able to handle 50 per cent more coal than the old slope, which has a 30 per cent grade. The latter will continue to operate. The construction of the slope was under the direction of James Pascoe, superintendent, and E. C. Lyle, local engineer. W. P. Williams had charge of the machinery. The slope was started about a year ago.

**Mount Pleasant Colliery**

Mrs. Kate Pettibone Dickson, of Scranton, Pa., widow of Alan Dickson, has sold this property to the Elk Hill Coal & Iron Co., a subsidiary of the Scranton Coal Co., as announced in *Coal Age* Nov. 19. The sale involves the transfer of 227 acres of coal land and 96 acres of surface property, including the site of the Mount Pleasant breaker. The consideration was $650,000, part of which was covered by a mortgage payable within one year.

## WEST VIRGINIA

The Island Creek Coal Co. on Nov. 24 declared a dividend of $5 on the common stock and also the regular quarterly of $1.50 on the preferred, both payable Jan. 1 to stock of record Dec. 15. In the preceding quarter the company paid an extra $1 besides the regular $2 on the junior issue.

A warning to mine operators to use rock dusting instead of sprinkling as a means of preventing explosions was issued Nov. 21 by R. M. Lambie, chief of the state Department of Mines, in connection with his monthly accident report.

The Wheeling Steel Corporation will erect an additional battery of 57 by-product coke ovens, to cost $1,000,000, at the present plant at East Steubenville. Production will be increased from 1,000 to 1,700 tons daily. Coal will be obtained from Harmarville, in the Pittsburgh district.

Announcement was made Nov. 28 by the Brady-Warner Coal Corporation, Fairmont, that R. M. Magraw, a mining engineer, who has been located in Colorado, Montana and Utah during the last 20 years, will become general superintendent of the company Dec. 1 to succeed John Whelan, formerly of Ohio, who resigned.

The New England Fuel & Transportation Coal Co. and the Jamison Coal & Coke Co., will soon start to rock dust their mines in the Fairmont region. The Bethlehem Mines Corporation is continuing the work started some months ago.

J. Edgar Long, of J. E. Long & Co., coal wholesalers of Clarksburgh, announced Nov. 28, after a return to the East, that the Acme Coal Co., composed of Eastern capitalists, had leased his various mining properties and were now operating them. Although newspaper reports previously carried similar information, it was not definitely announced until recently that the deal was definitely closed.

The Clarksburg District Mining Institute at its 68th monthly meeting in Clarksburgh, Nov. 28, decided to invite Robert M. Lambie, of Charleston, chief of the West Virginia State Department of Mines, to address one of the meetings in the near future. The annual meeting of the Institute will be held on Jan. 23 in Clarksburg.

Earl B. Beerbauer, of Fairmont, general superintendent of the Fairmont Gas Coal Co., on Nov. 27 assumed the duties of general superintendent of the Lincoln Hill Coal Co., near Washington, Pa. The mine is operated by a steel car company, which utilizes its own tonnage, according to reports. Mr. Beerbauer is making arrangements to dispose of his interests in the Fairmont Gas Coal Co.

The American Coal Co. of Allegany County has declared a dividend of $1 payable Dec. 21 to stock of record Nov. 30. This makes $4 paid this year.

The Baltimore & Ohio R.R. in October reports that mines on its system produced 3,756,570 net tons of coal, compared to 3,250,000 tons in September. On the Monogah Division there were 26,898.4 cars of the equivalent of 50 tons, and 18,733.9 cars on the Wheeling Division.

The Beechwood Mining Co. recently started its coke ovens at Beechwood, Monongalia County. They have been closed since the World War ended.

The Kingston-Pocahontas Coal Co. is installing a new tipple at its Springton operation, in Mercer County, and the Turkey Gap Coal & Coke Co. is installing a new washer at Hiawatha, Mercer County. The Miller Pocahontas Coal Co., operating on the Virginian, is making plans for the erection of two small tipples at its operation, it is reported unofficially.

The H. T. W. Coal Co., which recently took over the Alma Thacker property on Blackberry Creek near McCarr, in the Williamson field, has elected the following officers: J. W. P. St. Clair, president; John S. Hall, vice-president, and E. A. Hansbarger, secretary. Other stockholders are John L. Chafin and L. S. Spaulding.

The mining men in the Clarksburg section have organized their own mining extension class with an enrollment of 19, after the mining extension department of West Virginia University decided to concentrate on southern West Virginia and eliminate northern West Virginia this year, because of the existing labor troubles in the field.

Some of the work pursued in the mining extension department of Pennsylvania State College probably will be followed.

The Island Creek Coal Co.'s newest tow boat, the "Sam P. Suit" started on its maiden voyage from Huntington to Cincinnati, Nov. 21. The boat, which cost $175,000, is named after the general superintendent of river transportation for the Island Creek company.

A contract for twenty-five new miners' houses to be erected at Mine No. 4, on Laurel Creek, of the Coal River Collieries Co., is to be let, according to an announcement made by J. T. Dunigan, president and general manager of the company. The coal company has completed work on twenty-five new houses at the same operation and a new moving picture house and bath house are in the course of construction. A new recreation center also is projected.

The sale of the property of the Greenbrier Smokeless Coal Co. at Bellburn to interests headed by A. B. Crichton, of Johnstown, Pa. has been announced by Robert M. Bell, president of the concern. This purchase gives the Crichton interests control of 1,000 acres of coal lands on Meadow Creek adjoining lands already under lease. The Greenbrier Smokeless Coal Co. was organized by Mr. Bell, W. E. Nelson, W. B. Hines, H. H. Blackburn, Mason Bell and Edward Graff and began operations in the Greenbrier field in 1920, being the pioneer company in point of development in that field. The sale concluded involves property worth approximately half a million dollars.

Announcement is made of the appointment of C. A. Warden, formerly assistant to the general manager of the Kingston Pocahontas Coal Co., with general headquarters at Hemphill, as general superintendent of the company, which operates on an extensive scale in McDowell, Mercer and Fayette counties as well as in Pike County, Ky. Mr. Warden is to have supervision over operation, construction and store management. He has been connected with the company since 1910, having served in the capacity of mine superintendent, general superintendent of mining operations in Kentucky and assistant to the general manager.

One hundred and sixty-five frame houses will be built by the Island Creek Coal Co. at Holden, five miles above Logan, within a short time, company officials said last week after receiving initial bids from contractors. The cost of the new homes will be $200,000. The buildings will be four- and eight-room structures, and will house a substantial addition to the population of Holden, already one of the largest and best equipped mining camps in the state.

Circuit Judge Thomas R. Shepherd of the Circuit Court of Cabell County has overruled a motion to set aside the verdict of the jury for $122,500 in the suit of Charles W. H. Crane, of Cincinnati, against A. J. Dalton and J. A. Kelly, of Huntington. Crane based his suit upon a contract for the sale of approximately 49,000 acres of Wyoming County coal and timber land, contending that in the exercise of an option held by him Dalton and Kelly had agreed to pay him $5 an acre. The defense claimed that a partnership agreement existed between Crane, Dalton and Kelly and that the profits, if there were any, were to be divided. Sale of the land later, it was contended, did not show any profits.

J. W. Bischoff, who for a number of years was connected with the West Virginia Coal Co., has become identified in an important capacity, with the Kanawha & Hocking Coal Co., in the Kanawha field and will have his headquarters at Longacre.

With the dismantling of a wooden tipple at the river plant of the Island Creek Coal Co. at Huntington, that company is starting work on a new steel tipple which is to cost in the neighborhood of $250,000. The new coal loading apparatus is in partial use now and is handling 4,500 tons daily, an increase of 1,000 tons over the full capacity of the wooden tipple.

## WYOMING

M. W. Medill, assistant superintendent of the Union Pacific Coal Co. mines in the Rock Springs area of this district, has been elected Wyoming state president of the Izaak Walton League of America.

The Rock Springs Labor Temple Association has declared a 10 per cent dividend upon its capital stock of $27,500. The stock of the association is owned by United Mine Workers locals of the district.

Ten Chinese coal miners employed by the Union Pacific Coal Co. for an average of more than 36 years will be returned to Canton, China, due to old age and failing health. The company will pay expenses of the voyage and supply sufficient money to keep the men during the remainder of their lives. All are married, their wives living in the old country, and they will for the first time return to their native land since coming to America.

## CANADA

Officials of the Hamilton (Ont.) Chamber of Commerce and representatives of several large industries have entered a protest with the Dominion Board of Railway Commissioners against the action of the Canadian National and Canadian Pacific railways in raising the rates on coal from Port Stanley and Erieau from 90c. to approximately $1.50 per ton. The new rate will go into effect Jan. 1 and will seriously affect industrial conditions in Hamilton.

Alberta claims the distinction of being the first province in Canada to establish a research council, with laboratories and a staff under its own control. The present membership of the council is: Chairman, H. Greenfield, premier of the province; Dr. H. M. Tory, Prof. J. A. Allan, J. T. Stirling, Prof. N. C. Pitcher, Dean R. W. Boyle, and Prof. Edgar Stansfield, honorary secretary. The two main problems under study have been coal and road materials. Much work has already been accomplished in the determination and correlation of coal seams. Some 700 samples have been received since the formation of the council, but only the last 500 of these have been analyzed in the council's laboratories.

The production of coal at the collieries of the British Empire Steel Corporation during October amounted to 467,725 tons as compared with 427,122 tons for the month of September.

# Traffic

### Protest Maryland Rates

Rates on coal from the Cumberland-Piedmont region of Maryland are discriminatory to the extent that they exceed those from mines on the western slope of the Alleghenies or from the mines of the New River and Pocahontas districts, it is alleged in a complaint filed with the Interstate Commerce Commission by producers in the first mentioned field.

Freight rates on coke from Appalachia, Stonega and other producing points to California destinations are not unreasonable, in the opinion of Examiner Knowlton, who recommends that the Interstate Commerce Commission dismiss the complaint filed by the Romann & Bush Pig Iron & Coke Co.

The Gulf Coal Co., of Tams, W. Va., in a complaint filed with the Interstate Commerce Commission, protests against a rate of $1.13 per ton on coal from its Hot mine to Pemberton, plus New River district rates from Pemberton to destinations on the Chesapeake & Ohio R.R.

The Utah Traffic Shippers' Association has been organized to carry on a vigorous fight for fair transportation rates for this state. Among the important industries of Utah which it hopes to protect are coal, it is stated. The new association has strong backing.

# Obituary

**J. O. Reed**, 64, one of the leading spirits in the coal industry in the Clearfield region, died at his home in Philipsburg, Pa., on Nov. 23. Early in life he worked in the steel mills at Braddock, later became a bridge and car builder for the Huntingdon & Broad Top R.R. For a time he worked in the silver mines of Colorado and in 1897 assumed charge of construction of railroad cars for the Pittsburgh & Susquehanna R.R., the coal line which traverses the field between Ramey and Philipsburg. He became general manager of the railroad and later its superintendent and at the same time was general superintendent of the operations of the American Union Coal Co., which shipped over the road. He was a resident of Philipsburg for 22 years and served as a member of the Borough Council. He is survived by his wife and two daughters.

**J. R. Smith**, president of the Little Cahaba Coal Co. and of the Blocton Cahaba Co., of Alabama, was found dead in bed at his home in Fayetteville, Tenn., Nov. 20. He was buried in Birmingham, Ala.

## Coming Meetings

**Smokeless Coal Operators' Association.** Annual meeting, Dec. 10, at Washington, D. C. Secretary, E. J. McVann, Washington, D. C.

**Coal Mining Institute of America.** Annual meeting, Dec. 9-11, Pittsburgh, Pa. Secretary, H. D. Mason, Jr., P. O. Box 604, Ebensburg, Pa.

**American Mining Congress.** Twenty-eighth annual convention, Dec. 9-11, Washington, D. C. Secretary, J. F. Callbreath, Munsey Bldg., Washington, D. C.

**American Wood Preservers' Association.** Annual meeting, Jan. 26-28, 1926, at Cleveland, Ohio. Secretary, E. J. Stocking, Chicago, Ill.

**Coal Club of Philadelphia.** Annual meeting, Jan. 28, 1926, at the Bellevue-Stratford Hotel, Philadelphia, Pa. Secretary, C. K. Scull, Philadelphia, Pa.

## New Companies

**The Glen Jean Smokeless Coal Co.,** with a capital of $25,000, has been incorporated by J. M. Turner and C. M. Faulkner, both of Huntington, W. Va.

**The Paramount Coal Co.,** of Middlesboro, Ky., a consolidation of the Bellman Coal Co., Winna Coal & Coke Co. and the East Point Coal Co., with a capital of $63,000, has been incorporated by J. L. Manring, W. E. Cabel and R. E. Howe.

**The Coal Creek Co.** has been incorporated in Henryetta, Okla., with a capital of $10,000, by Frank Barrow, J. R. Hopkins and others, and will open a coal mine.

**The North State Coal Company** with a capital of $20.000 has been incorporated by Junius H. Harden and E. L. Henderson.

**The Rock Forge Coal & Coke Co.,** capital $10,000, has been incorporated at Morgantown, W. Va. The incorporators are James Moreland, Preston Road and Robert E. Guy.

**The Sutton Coal & Coke Co.,** capital $25,000, has been incorporated at Sutton, W. Va. The incorporators are J. W. Johnson and Van B. Hall.

**The Payne-Baber Coal Co.** has just been organized and will have its offices in the Union Bank Building at Huntington, W. Va. It is headed by E. J. Payne, formerly of the Lake & Export Coal Corporation. Associated with him is B. C. Baber, well known in the coal trade.

## Association Activities

C. W. Henderson, president, Cambria Coal Mining Co., of Knoxville, Tenn., was re-elected president of the **Southern Appalachian Coal Operators' Association** at the annual meeting in Knoxville Nov. 20. Broadening of the statistical work of the association was authorized. The report of Secretary Howe showed increasing membership and a strengthened position of the local association. Mr. Gandy discussed the work of the National Coal Association on behalf of the industry. J. E. Johnson, secretary, Kentucky Mine Owners' Association, briefly told of the efforts of that association in combating a tonnage tax proposal in Kentucky, inasmuch as quite a portion of the operations of the Southern Appalachian Association is in that state. A meeting of the Southern Appalachian Efficiency Association, an auxiliary of the local operators' association, also was held, at which E. V. Albert, superintendent, and A. G. Hahn, mine inspector, United States Coal & Coke Co., Lynch, Ky., discussed safety efforts. Judge H. B. Lindsay presided as toastmaster at a largely attended banquet at the Cherokee Country Club in the evening, at which there were various entertainment features and addresses.

**The Cincinnati Coal Exchange,** at a meeting Nov. 17, voted to change the constitution so that associate members might be admitted. This matter has been hanging fire since Feb. 5, when Ernie Howe, Fred Legg and George Kearen were appointed a committee to study the move. The Exchange, being a subsidiary, had to have power granted to make the move from the Chamber of Commerce. Then the point arose whether the associate members would be allowed a voting privilege. When this question came up the matter was referred back to the committee. The associate members will not have power to pass upon any questions voted on.

The annual business session of the **Harlan County Coal Operators' Association** at Harlan, Ky., Nov. 18, was well attended. R. C. Tway, after seven years as president, declined re-election and was succeeded by W. A. Ellison, vice-president, Mahan-Ellison Coal Corporation, of Harlan. J. P. Johnson, general manager, Crummies Creek Coal Co., Cawood, Ky., was elected vice-president. Secretary Clayton's report showed the association to be in strong condition. In the afternoon all of the operators and guests were taken on a special train to Lynch, Ky., for inspection of the mine of the United States Coal & Coke Co., which included seeing a combination cutter, conveyor and loader in actual operation. The banquet, which was held in the evening, tested the seating capacity of the largest room in Harlan, Judge H. B. Lindsay, of Knoxville, acting as toastmaster. W. A. Northcutt, of Louisville, Ky., general solicitor of the L. & N. R.R., spoke on the development of the coal industry in Kentucky and Tennessee, and urged close relationship between operators and the road. George W. Malcomson, Detroit, Mich., presdient, Harlan Gas Coal Co., spoke of the necessity for trade extension and service work, and told of the proposed organization of a fuel research institute in Detroit. Executive Secretary Gandy spoke on the work of the National Coal Association and the Congressional situation. George F Neel, Draper, Ky, general manager of the East Harlan Coal Co., on behalf of the local association, presented retiring President Tway with a gold watch.

## Industrial Notes

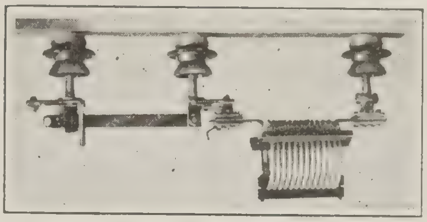
**The Superheater Co.,** of New York and Chicago, announces the appointment of R. L. Ehmann as district manager of its industrial department, with an office at 923 Union Trust Building, Pittsburgh, Pa. The former manager, of the Pittsburgh office, John R. LeVally, has been assigned to special duties with the company and may be reached through the New York office.

The **McGraw-Hill Co.** has purchased the **E M F Electrical Year Book,** published by Electrical Trade Publishing Co., Monadnock Block, Chicago. The 1926 edition, which will be out April 1, 1926, will be edited by the staff of the Electrical Trade Publishing Co. and sold by the staffs of both organizations. Headquarters for the Year Book until completion of the 1926 edition will be at the offices of the Electrical Trade Publishing Co., in Chicago, but information and data may be obtained from men of both organizations. This standard reference book will supplement the service of McGraw-Hill electrical publications by supplying the reference information needed by buyers and specifiers throughout the industry.

# New Equipment

## Protective Units Are Now Simplified

A combination disconnecting switch, fuse, and choke coil, designed to reduce the size and weight of the combined unit as well as the number of insulators required is a new product of the Westinghouse Electric and Manufacturing Co. The possibility of trouble through insulator failures is thus reduced, and a saving in initial and upkeep costs is effected.



Choke Coil and Switch Are Mounted Together

This combined unit, mounted on three insulators, is available for service requiring underhung or slanted insulators.

Insulator assemblies similar to those used with other fixtures are employed with these combinations. These standardized insulator assemblies employ only three-bolt circles for the complete line. Two types of outfits are available, one with underhung and the other with inclined insulators, both of which use the same assemblies for a given voltage rating. The insulators have sanded heads and pin holes which adhere firmly to the cement. All hardware is galvanized and is provided with cupped and ribbed holding surfaces from which the cement cannot slip. The cement, used at both cap and pin, is steam set so that injurious stresses due to temperature changes will be avoided. The combinations are available for all voltages up to and including 110,000 volts.

## Change Over Switch Provides Continuous Service

An automatic change-over switch, that has for its chief application installations where continuity of service is the primary feature, and where interconnected secondaries are not available, has been designed by the Westinghouse Electric and Manufacturing Co. It has a full automatic feature which functions to keep the main contacts on a selected circuit, so long as that circuit is energized, and which assures the operator that his feeder loads are properly distributed under

Makes Quick Circuit Change

A transfer switch such as this automatically connects itself to one energized circuit or another.

normal conditions. Another feature of this switch is that by opening a single-throw knife-switch the main contacts can be thrown from the main to the auxiliary circuit, and by closing the knife-switch the contacts will be returned to the preferred circuit.

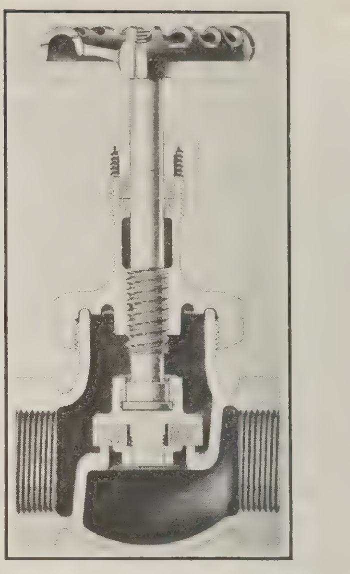
This switch depends for its operation on the action of an undervoltage release coil. The wiring is such that when the voltage fails in the preferred circuit, the low-voltage plunger will fall. This completes the circuit from the instrument transformer on the auxiliary circuit through the drum switch on the shaft of the operating mechanism to the trip coil. The trip coil raises its plunger and allows the main drum to revolve through an arc of 180 deg. This throws the main contacts of the breaker from the preferred circuit to the auxiliary circuit.

In construction this switch, which is essentially a three-pole, double-throw, full automatic oil circuit breaker, with a low-voltage release attachment, is sturdy and compact. The oil tank is lined with micarta, while tubes of the same material protect all incoming and outgoing terminals. The main contacts are of the familiar wedge and flexible finger type and the operating drum, mounted directly above the oil tank, is protected by a dust-proof cover through which a shaft extends. No attention is required by this automatic switch other than the usual monthly inspection.

## Improved Type of Globe And Angle Valves

For working steam pressures at 225 lb. a new line of medium pressure bronze globe and angle valves has recently been placed on the market by Jenkins Bros., of New York. They are designed to meet the need for a valve with a renewable disk that will satisfactorily handle higher pressures than those recommended for the standard pattern.

An important detail of the new valve is the bonnet and union, made in one piece to screw on to the outside of the body thread. This construction affords strength to the body and as the bonnet hexagons are large they allow the bonnet to be easily removed without distortion. Of special interest also is the "ball joint" formed when the bonnet and body are screwed together. This is a new feature and makes a strong, though easily removable joint.



**Cross-Section of New Valve**

Chief advantages of this valve lie in the ball joint between body and bonnet, the large bonnet hexagons, the composition disk, heavy stem and large stuffing box.

These valves are regularly fitted with a composition disk for high-pressure work. This will appeal to those who recognize the superiority of this construction over the metal-to-metal seat. No regrinding is necessary in order to insure a tight valve. The spindle is made of manganese bronze, with large threads which are all in contact when the valve is closed. The stuffing box is deep, affording plenty of room for packing, which is compressed by means of a bronze follower or gland. A ventilated hand wheel of malleable iron is furnished. This line of valves can be had in either the globe or angle type with screwed or flanged ends and in sizes ranging from ¼ to 3 in.

## Trade Literature

**Note the Float.** Sweet & Doyle Foundry & Machine Co., Troy, N. Y. Bulletin No. 8. Four-page folder illustrating and describing the Condensation Eliminator for the removal of entrained water.

**Type M Automatic Change-Over Switch.** Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. Leaflet L-20234. Four-page folder outlining the construction, application and distinctive features of this automatic change-over switch.

The Crouse-Hinds Co., Syracuse, N. Y. has issued Folder No. 28 and Bulletin No. 2080 illustrating and describing its **Tumbler Switch Condulets**, especially adapted for switches subjected to severe conditions.

**Midwest Air Filters, Inc.** and **Midwest Steel & Supply Co. Inc.**, have moved their Headquarters from New York City to Bradford, Pa., effective Nov. 7. This move is simply to concentrate all effective personnel at the factory proper, in order to consolidate organization, eliminate duplicate effort, and maintain a closer control of company activities. A branch sales office will be maintained in New York at 100 East 45th Street.

**Engineering, Surveying and Mining Instruments.** C. L. Berger & Sons, Inc., Boston, Mass. Pp. 194; 6 x 9 in.; illustrated. 40th edition. Describes its monitor transits and levels.

**Foxboro.** The Foxoboro Co., Inc., Foxboro, Mass. Bulletin No. 96-1. Pp. 24; 4 x 9 in.; illustrated. Describes the different types of indicating, recording and controlling instruments made by this company.

**Power Shovel.** The Osgood Co., Marion, Ohio. Bulletin 2514. Pp. 11; 8½ x 11 in.; illustrated. This shovel, designed for operation by gasoline or oil engine, or by electric motor, is described and pictures of it in operation are shown.

**Materials Handling.** Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. Motor Application Circular 7378. Pp. 29; 8½ x 11 in.; illustrated. This booklet is divided into two sections, the first one covering the principal groups of material-handling machines, and the second describing the various types of electrical equipment that this company has developed for material-handling machinery.

**Superior Speed Reducers for Every Service.** De Laval Steam Co., Trenton, N. J. Pp. 16; 6 x 9 in.; illustrated. Describes the many operations in which the De Laval worm reduction gear is used.

The Allis-Chalmers Mfg. Co., Milwaukee, Wis., recently issued the following bulletins: Bulletin No. 1228, describing and illustrating its **Allis Texrope Drive**; bulletin No. 1823, covering its **Crushing Rolls**, and bulletin 1123, describing its **Polyphase Induction Motors.** These bulletins are all 8 x 10½ and well illustrated.

The Griscom-Russell Co., 90 West St., New York City, recently issued a four-page folder, designated as form 411, on **Heat Transfer Equipment.**

## The President Writes a Blank Check

THE ADMINISTRATION PROGRAM on coal, as outlined in the President's message to Congress this week, offers nothing new or novel. For guidance in dealing with an industry which already "has been the subject of repeated investigation and reiterated recommendation" President Coolidge presents a restatement of the position he took in his message on the same subject two years ago. Such differences as exist between the two documents are largely differences in phraseology, not differences in ideas. Price is no longer specifically mentioned, but protest is again registered against a legislative status which leaves the national government "so powerless that its only attitude must be humble supplication" in times of emergency.

The President, as in 1923, ventures a non-committal indorsement of the conclusions of the Hammond coal commission. The report of that body, he tells Congress, "should be brought forward, reconsidered and acted upon." Only two recommendations of the many made by the commission, however, have been emphasized in the President's message. These are emergency control and regional consolidations. Into the latter, the President reads a need for "more freedom in the formation of marketing associations, under the supervision of the Department of Commerce." On the key to the control recommended by the Hammond fact-finding agency—the creation of a coal division within the Interstate Commerce Commission—the President is silent.

In an official pronouncement so broad in its implications, so meager in particularization, it is impossible to determine just where the national administration stands. A meticulous critic might ask for a definition of "modern methods of adjusting differences between employers and employees" before subscribing to the opinion that present management "is very close to a national economic failure." He might point to the acrimonious wrangling over railroad consolidations since the merger clauses were written into the Transportation Act of 1920 as proof that bureaucratic acceleration of combinations is not an infallible substitute for economic laws. And the possibilities of academic discussion of the pitfalls of emergency control to bring recalcitrant labor to a sense of its public responsibilities are almost limitless.

But, in the absence of a clear-cut, definite program for dealing with these questions, such discussion must be largely futile. It is this absence of clear-cut, definite, detailed proposals, however, which makes the situation created by the President's message dangerous to the coal industry and to the nation. We cannot come to grips with realities because the message is vague. It may mean anything, everything or nothing. That indefiniteness is the politician's opportunity. The Borahs, the Oddies, the Treadways and the Blacks can bring in bills embodying almost anything short of nationalization—and who can say that their ideas are or are not consonant with the Coolidge program?

Nothing illustrates better the tremendous problems involved in coal than the indefinite character of the President's message. Mr. Coolidge has undoubtedly had the advice of men who have given close study to the situation. Nevertheless, despite this counsel, the President is not ready to present a definite program. It reveals a spirit of caution which might well be emulated in other quarters.

## Leisure or the Forward Step?

NOBODY CAN TELL what the anthracite miners really want. They are asking for more pay, it is true, but they could have had that at any time by working more hours or more steadily and that without arriving at an eight- or even a seven-hour day.

So it appears that they want the same pay at less hours or less effort. If that is the case most of the plans for greater efficiency that the mechanical engineers are urging and which are based on intensive effort and a full eight hours of work would not afford the miner just that for which he is striking. Perhaps, however, the strike is neither for wages nor for leisure but for that "forward step" which the anthracite mine workers, like labor in general, are always desiring. There are, however, natural limits to such progress.

## The Last Ounce of Energy

FOR THE PREVENTION of accident and breakage of material we have introduced factors of safety. We don't demand the last ounce of our ropes or of our metal parts, but why not have a factor of safety for our locomotives and motors? Why load them to the limit? To avoid some of such excessive loading we have fuses and circuit breakers, but why reach such loads as burn fuses and throw out breakers? The better way is to keep well within such loads so as to keep the machines continuously in operation.

It is best to arrange that no more than a certain number of coal-loaded cars and a certain number of rock-laden cars be hauled in a trip, not for safety but for certainty of operation. No plant is running with assurance if it is using the last ounce of its available effort. The factor of certainty of operation is almost as important as the factor of safety. Those who expect to get a given tonnage day by day cannot afford to neglect it. Some foremen believe in making every trip the largest load the locomotive can haul—the lazy man's load—but a better plan is to go more often to the sidetrack and to haul the coal without interruption. If a bad grade interferes with movement the demand for power should not be increased. Instead the load should be eased if it can be done by a better grade.

At one mine where there were twenty-one locomotives, requisition was made for two more. Instead of complying with the requisition an inquiry was made. It was found by lessening the number of cars behind some of the locomotives they could be assured against stalling and consequently could make more trips, hauling more coal than ever.

Many managers fix a limit on the length of trips to avoid slow speed, stops, circuit breaking, fuse burning and whatnot, and when they can't safely fix the length of trip to suit their ideas they scan the grades which are making the trouble, and with a night force correct the annoying restriction. The stupid waste of time on short hills is one of the aggravating features in much mining practice. What we need is not so much a boss driver as a traffic master with ideas and imagination and in a large mine a train dispatcher working under him.

## Quality of Coal

A DEALER in high-grade products has a standing in the community as excellent as his goods. A cheap-John, a maker of honest goods perhaps but of low quality for those who are willing to accept a low standard, has a low reputation among his fellows. A man whose goods are brummagem has a repute as low as his products.

Consequently, the coal industry, if it would establish itself, must seek to attain a reputation for producing a high-grade commodity. It must not try to pass off just what the public is accustomed to or may be induced to take. Standards must be higher. What does a man do when he finds that a tool he has bought curls at the edge? Does he say that iron will curl and remain satisfied or does he declare that the tool should be of steel of such quality that good work can be gotten from it?

None of us wants poor goods. Why then will some men try to sell them? In any attempt to be favorably regarded by the public eye, clean coal is one of the first steps, just as the manufacture of hard and durable steel is the first step that a tool-steel manufacturer takes to establish his reputation. This seems elementary reasoning, but with some coal operators it has not sunk deeply enough. Some are glad that other coals are dirtier than theirs because that fact helps sales. It's true it does, but the unfortunate fact is that the poor coal on the market, which aids the sales of clean coal, spoils the reputation of every coal producer and of the entire industry.

## Everybody's Business

SO UNIVERSALLY are we moved by self-interest that the man, unless he is paid for his action, who tells another what he should do to protect a third party is said to be meddling. So perhaps it is just as well that the fatalities due to coal dust and gas have so interested and excited the public that a mine operator who enforces safety practices now without censure can criticise his lax neighbors on the ground that they are laying not only their own but all mines open to the liability of government regulation and to reprobation of the public which will make the conduct of the coal business difficult.

Sentiment ought to be rampant in regard to rock dusting. The man who delays it or does it in a niggardly manner and the man who does not do it should be put on an attitude of defense not only as against the mine inspector but as against the operators in his field and every other field. It is not a matter to meditate on and discuss and leave for a later date. Let every operator who hasn't a dusting machine dust his mine with a shovel till he can get the necessary equipment. There is no valid reason for delay. It will be a crowning disgrace if a single dust explosion occurs this winter, and the man who has it will be putting the coal-mining industry before the public in the worst possible guise.

We may not be able to improve loading practice in a single year or two or even three, but we can mobilize for rock dusting in a few weeks. It was a truly sorry tale Captain Steidle told at the West Virginia Coal Mining Institute. We have done so little, as he showed, to make our mines immune since the movement got well started by the passing of the Utah regulations.

This rock dusting is everybody's business. The trade associations would do well to take it up, and the institutes. The industry should show itself a unit in putting this form of safety over. It is one of the first factors in better public relations.

## The Cool of the Mine

SOMETHING IN MINES is attractive, or underground mine workers would not be so unwilling to accept surface work. That thing is the cool air. If the surface worker were as well protected against heat as the worker in the coal mines, only the wage would be alluring in coal mining.

It will not be long, however, before the office and even the home will be kept, if not as cool as the mine, at least as comfortable and free from excessive heat. At the Luray Cavern, a show place in Virginia, a sanitarium was built on the hill and connected with pipes that ran down to the cave. The escaping air kept the sanitarium cool through the long summer days. Today the house, no longer a sanitarium, is cooled in the same way.

Under the city of Chicago are a series of tunnels used for freight and wires. These tunnels are cool at all times, and for a while some of the motion picture houses were kept cool with the effluent air from these tunnels.

The mines in the future will be the means by which the homes, hospitals and motion picture houses will be kept cool, but not with the cool air of the excavations. Coal will furnish the power which sets the refrigeratory machinery in operation. That such coolness is appreciated is well illustrated by the remark of a woman whose husband was a sewer digger. He came home late one night for dinner and she objected. "Here am I," said she, "moilin' all day over this stove agettin' of your meals, and you down in that nice cool sewer!" There are compensations in coolness and, let the coal trade be well advised, profit also. The coolness of the mine is a suggestion for future expansion in coal demand.

RESILIENCE MAY BE MORE IMPORTANT than hardness in resisting wear. Thus rubber is giving good service in ball mills, and in pump impellers. It has done excellent work as elbow parts in pipe lines delivering concrete where manganese steel and cast iron failed. Perhaps we shall come to the use of rubber, soft or hard, for chutes, launders and flushing pipes in back filling.

# Good Power Factor Conditions Always Serve to Lower Capital Charges and Energy Costs

## Careful Selection of Apparatus Is Most Necessary—Corrective Equipment Now Available Permits Power Devices to Carry Larger Loads and Reduces Bills—Applications of Synchronous and Static Condensers

**By Edgar J. Gealy**
Associate Editor of *Coal Age*,
New York City

WHETHER A COAL COMPANY generates its own electrical energy or purchases it, good power factor conditions on its lines are always desirable and economical. Where poor power factors exist excessive capital must be laid out to carry idle currents. Wires, poles, insulators, crossarms, switches, transformers and motors must be of larger capacity than would be required if the power factor were good.

From an operating point of view serious difficulties arise because of high circulating wattless currents; voltage regulation becomes bad, line drops are large, motors will not develop their rated torque, switches and fuses needlessly interrupt service, conductors get hot and high maintenance costs result.

Many coal companies have given the question of power factor correction but little attention. This is either because they generate their own power or purchase it from a utility company which has not seen fit, as yet, to enforce the penalty clause which is no doubt in all its power schedules.

These difficulties and costs produced by poor power factors may exist either with coal company generated energy or custom power purchased without a penalty charge. Whatever expense is added to the power bill when the penalty clause is enforced is really an additional cost.

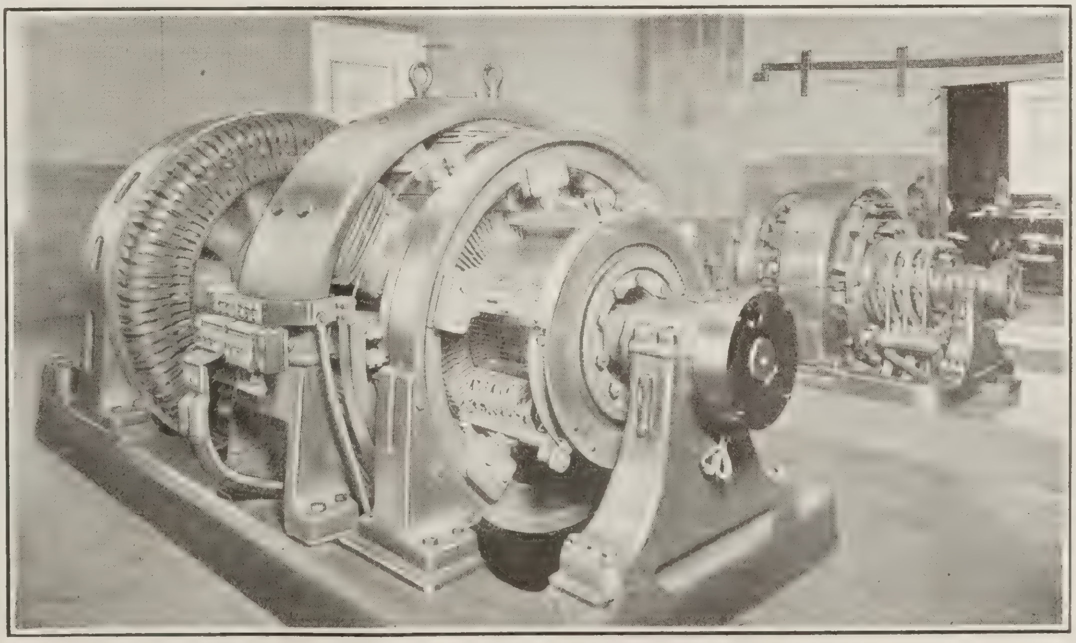
A penalty charge upon a power bill is perfectly reasonable and justifiable from the power company's point of view. Wattless currents necessitate capital investments in power plants, generators, wires, transformers, etc., which earn no income unless a special charge is made. Ordinary meters do not register wattless current; the idle current does not turn their elements.

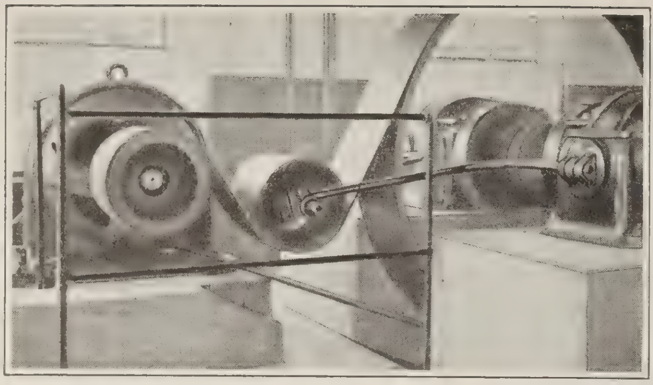
Obviously, if the power company's penalty charge is justifiable, because of the additional investment in equipment thus made necessary, the user of power has an added expense due to this same wattless current circulating in his apparatus. In fact, this matter is more serious to him because it affects his production also. For example, if an induction motor receives 10 per cent less than normal voltage, because of poor power factor conditions, its torque is reduced nearly 20 per cent and it can do less work. A larger size motor to replace this one would require more capital and in fact, when applied to the load would aggravate the condition.

Power customers who buy energy under a schedule with no penalty clause actually do pay for having poor power factor loads. This they may not know but, nevertheless, it is true. Great improvements have been made lately in the processes involved in the generation, distribution and sale of public utility energy. All of these advantages have not been reflected in reduced power rates. Rather than enforce a penalty clause for poor power factor many power companies have chosen to let the customer pay this charge, perhaps unknowingly, in an energy rate which has not completely reflected the improvements made in power plants.

**Near the Cause**

The motor-generator set in the foreground has a 440-volt synchronous motor. It receives its supply from the low-voltage side of a bank of transformers which feeds the induction motor load of the Baker breaker of the Glen Alden Coal Co. Thus the leading current taken by this unit counterbalances the lagging current of the breaker motors.





**Units in All-Day Service Are of Great Value for Corrective Purposes**

A small synchronous motor is shown here driving an air compressor at a mine of the Hillside Coal and Iron Co., in Forest City, Pa. Units like this one though small do much to correct lagging currents of hoist motors which must be of the induction type.

Power factor correction begins with the prevention of conditions which produce high wattless currents. When laying out or surveying an electrical system with the idea of obtaining good power factor operation the following points should be considered:

(1) At nearly all mines certain types of loads lend themselves equally well to either direct-current or alternating-current motor drive. Under some circumstances instead of using an induction motor, it may be advisable to select a direct-current motor which receives power through a synchronous motor-generator set or rotary converter. Whenever there are no serious drawbacks to this arrangement, the possibility of obviating at least some inductive load presents itself right here.

(2) In the selection of an induction motor its power factor characteristics should be given careful consideration. The type and design of the motor should be such that it will meet the load conditions and at the same time operate at high efficiency and good power factor, especially at its normal load. High-speed induction motors have the best power factor characteristic curves.

When calculating or otherwise determining the size induction motor required for a given service it is always desirable, consistent with load and operating conditions, to select a motor which is no larger than properly required. Induction motors operate at their highest efficiencies and best power factors at or near full load. Hence, if a load is over-motored it necessarily operates at an efficiency and power factor which is less than the best obtainable.

(3) A synchronous motor should, in general, be applied to all loads which can be driven successfully by this type of unit. It may even be advantageous at times to adopt special means or devices to make the use of this type of motor possible.

(4) The use of special type machines such as combination induction- and synchronous-motor units should be considered. Motors and devices of this nature are rapidly becoming standardized.

(5) Transformers should be selected with the same care as induction motors. Because transformers usually are permanently connected to their lines, considerable reactive-current hours may be registered by them.

(6) The synchronous condenser may be applied either to prevent poor power factor conditions or to correct the power factor of a line. In the first instance it would probably be designed to carry a mechanical load, while in the second case it may be floated on the line and merely supply leading current.

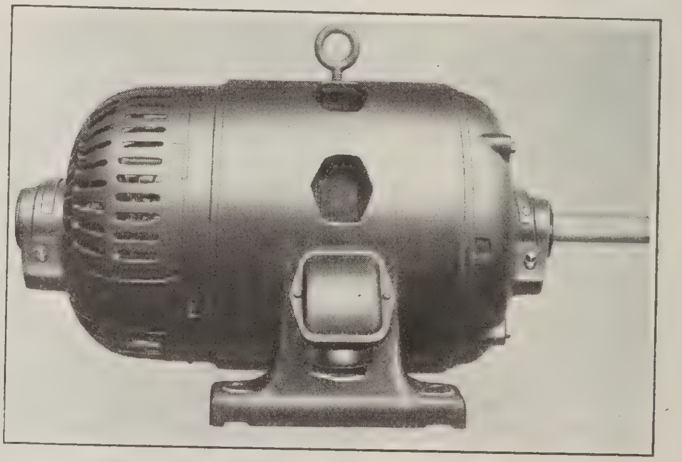
(7) Static condensers generally perform no other function than the correction of poor power factor conditions.

Oftentimes the design and operating conditions of a mine hoist permit the use of an induction motor drive or a direct-current drive. In such instances here is an opportunity to consider the desirability of selecting an induction motor with its high inductive current or a direct-current motor receiving power through a synchronous motor-generator set or a rotary converter.

Again, the haulage system of a mine nearly always necessitates the use of direct-current locomotives. When the feeders are properly designed and other conditions satisfactory it may at times be advisable to operate mine pumps, small hoists, air compressors, coal cutters, etc., by direct-current energy supplied through a motor-generator set or rotary converter rather than by alternating-current induction motors.

The best motor for a given duty is usually that type which gives the greatest reliability, has suitable torque, good speed characteristics and the highest efficiency. The induction motor has these characteristics and is exceptionally low in price. It, however, possesses a disadvantage in that it draws a large lagging current from its supply line. This reactive current is almost as large at light loads as at full load. The data in the accompanying table makes this fact quite clear. If the motor is applied to a constant load equal to its full load capacity, the power factor will be maximum at all times. It is apparent however, that the ratio of the reactive current to the energy component increases under light loads and consequently the power factor becomes low. The selection of the proper induction motor, therefore, plays an important part in obtaining a good power factor for a plant or power system.

Synchronous motors are designed to operate at unity power factor or leading power factor. When applied to a circuit having a lagging power factor, the resulting power factor is always nearer unity than before. Synchronous motors may be designed for the purpose of carrying full capacity mechanical load or any percentage of mechanical load to none at all. Obviously, a machine designed for the purpose of carrying a high reactive current and no mechanical load is of lighter construction than one built to drive machinery.



**A Motor Combining Two Types Has Been Built**

This relatively new type motor embodies the characteristics of an induction motor and a synchronous motor. At normal loads it is a synchronous unit, but while being started and when highly overloaded it acts like an induction motor.

All types of synchronous motors have their fields of application depending upon the conditions to be met and the results to be obtained. Slow-speed synchronous motors generally are designed to operate at unity power factor. This is because the increased cost of material and lower efficiency resulting by making these slow-speed types suitable for leading power factor become governing considerations.

High-speed synchronous motors may more economically be designed for leading power factor service. These motors are highly recommendable because they provide a means of adding both mechanical load and obtaining power factor correction at the same time. In nearly all power systems a high power factor load does more to correct a lagging power factor condition than large purely reactive capacities provided by synchronous machines floating on the line and not carrying any mechanical load.

Standard synchronous condensers usually are designed to carry mechanical loads up to 70 per cent of their kilovolt-ampere rating. Such a motor when used in this manner provides maximum economy as to first cost of mechanical motor capacity and also as to leading reactive kilovolt-ampere capacity.

Synchronous motors should usually be operated with their field excitation set to correspond with the full rating of the machine. If this is done the reactive capacity will become proportionately more favorably effective at loads less than full. The power factor characteristics of a synchronous motor are in general as shown in Fig. 1. Within certain limits the load at which unity power factor is attained can be increased or decreased by adjusting the excitation of the field. When the machine operates at loads less than that at which unity power factor is attained it takes a leading current, while at higher loads it takes a lagging current and as the load is further increased the power factor characteristic becomes similar to that of an induction motor.

A synchronous converter or rotary converter, as it is sometimes called, lends itself less readily to power factor correction than a synchronous motor because its field can be varied between narrow limits only. Attempting to operate beyond definite limits upsets the balance of the machine and causes serious operating difficulties.

No doubt one of the main reasons why the synchronous motor has not been more generally used, until recent years, is that many of its characteristics are not thoroughly understood. Some of its inherent advantages, nevertheless, embody just those qualities which many electrical men have been seeking. For example, under low voltage conditions, the reactive kilovolt-ampere capacity available for improvement of power factor increases; whereas, under conditions of high voltage the leading reactive kilovolt-ampere capacity available for power factor correction automatically decreases. At abnormally high voltages a synchronous condenser might actually draw a lagging current from the line

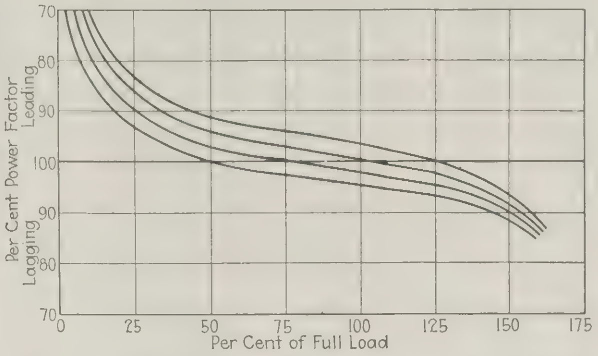


**Fig. 1—Power Factor Characteristic of Synchronous Motor Leads and Lags**

These curves show the approximate shape of the power factor curves of a synchronous motor. Depending upon the field current applied, the motor may operate with leading current until the load reaches any predetermined value. Ordinarily a synchronous motor should be supplied with nearly full field excitation so that it will take a leading current most of the time and thus aid materially in correcting power factor.

### Characteristics of Three-Phase 60-Cycle Motors

| Horse-power | Speed in R.p.m. | Volts | Full Load Eff. | Full Load P.F. | Kva. Input | Approximate Reactive Kva. Full Load | Approximate Reactive Kva. No Load |

**Slow-Speed Motor Drives Breaker Machinery**

Here is a breaker motor used by the George F. Lee Coal Co. to help reduce the power bill. The motor is started under no load and then connected to the equipment which it drives by means of a magnetic clutch.

and thus hold down the line voltage. Such action tends to stabilize line pressures.

The pull-out torque of synchronous motors varies directly with the voltage, although, under starting conditions the starting torque and pull-in torque vary as the square of the voltage, being similar in this respect to an induction motor. This latter characteristic is easy to understand when we remember that nearly all synchronous motors are started by the use of windings, incorporated in their design, similar to those on an induction motor.

### Advantages of Synchronous Motor

Aside from the benefits of power factor correction possible with a synchronous motor, it has several other advantages. Slow-speed synchronous motors are generally more economical in operation and less expensive than slow-speed induction motors. For certain kinds of service such as on air compressors, motor-generator sets or processes necessitating uniform speed the synchronous motor is especially suitable.

Synchronous motor-generator sets supplying direct current for mine service are highly desirable. They maintain constant speed and hence good direct-current voltage regulation. A rotary converter applied to service with an unvarying load, but rarely found at coal mines, is more efficient and probably less expensive in first cost but its characteristics are such that flexibility of operation to obtain power factor correction is limited.

A compound wound synchronous converter, such as is used in mining service, is designed to operate at unity power factor between the limits of full load and three-quarter load. For mining service it has a serious disadvantage, realized more and more, in that the direct-current voltage varies in proportion to the alternating-current supply voltage. With the synchronous motor-generator set the generator speed is always constant and the direct-current voltage is independent of any alternating-current voltage fluctuations.

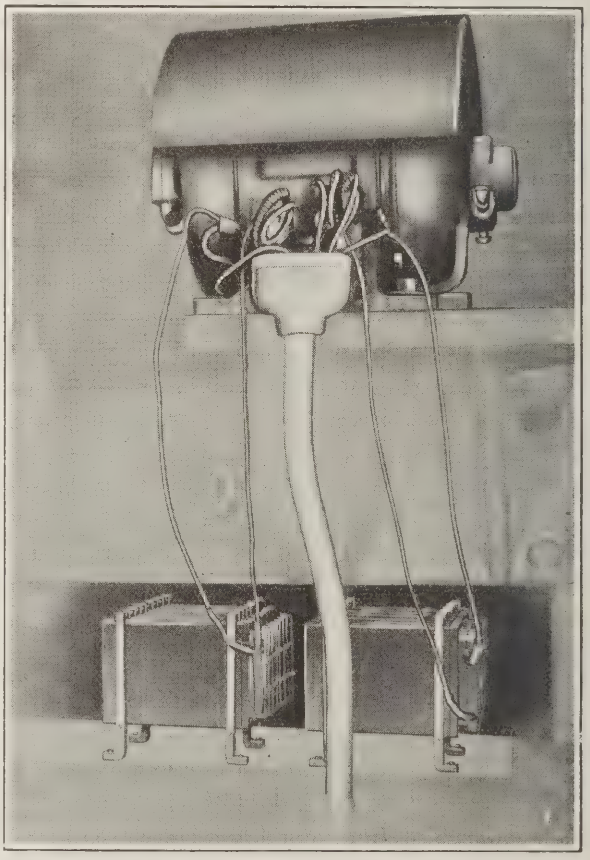
Heretofore it generally has been thought that the synchronous motor is applicable only to operations or machines requiring constant speed and infrequent starting, also to loads with low starting and pull-in torques. In many cases this is true, but improvements in motor design, in magnetic clutches and other auxiliary starting devices have greatly broadened the usefulness and application of synchronous motors.

To meet the increasing demand and necessity for those qualities possessed only by synchronous motors, many different types of special motors have lately been designed. Some of these machines are combination types embodying both induction- and synchronous-motor characteristics. Another type is the commutating alternating-current motor. Some of the most successful new motors are types designed with a clutch of some kind so that the high pull-out torque of a synchronous motor can be used during starting service.

### Transformers Exert Influence

It has been believed generally that transformers exert little influence upon power factor conditions. This is not true and becomes most apparent when the customer purchases power upon a schedule which permits the power company to increase its rate by means of a power factor clause in its contract.

Ordinarily, the magnetizing current supplied to a bank of transformers is relatively small but when we consider the fact that transformers usually are connected to the lines the full 24 hr. of every day, the total reactive current hours passing through them becomes exceedingly large in the period of a month. Over-transformered loads are to some degree in the same category as over-motored loads. In cases where three single-phase transformers are too large for the load it may prove advantageous to operate only two of them at a time, connecting them in open delta. In this manner both the no load losses and magnetizing current may be appreciably reduced.



**Compensate for Lagging Currents at the Source**

The closer a static condenser is applied to the place where lagging power factors are originated the better becomes its service because correction is accomplished before wires, switches and transformers are loaded with idle current.

The lagging current taken by a transformer may be only 5 per cent of the full load current, but when we consider that the load factor of most mine equipment is low, the magnetizing current ampere hours become proportionately much larger than 5 per cent of the average power load upon them.

After everything possible has been done in the selection of equipment, that is, proper size motors have been applied, transformers have been carefully selected and the opportunities for the use of synchronous motors have been exhausted, etc., it is first of all necessary to see that such equipment is operated to give the best power factor conditions. Then if further power factor correction is necessary attractive results can be obtained by the use of synchronous condensers and static condensers.

### CORRECT NEAR PLACE OF ORIGIN

When endeavoring to correct poor power factor every reasonable effort should be made to do so at or near places where it originates. Aside from the benefits derived in the power bill the user should consider the other advantages he can gain for himself. High wattless currents needlessly tie up capacity in wires, switches, meters, transformers, alternators, etc., which might otherwise be used for useful work. Often the necessity for buying new transformers or additional alternating-current generating capacity to carry additional loads can be obviated by correcting power factor on the load side of such units already in service. Therefore, in applying corrective equipment the first thought should be to locate it where it will reduce reactive currents before they pass through transformers, switches, wires, etc. Consistent with this idea, small-capacity condensers suitable for use on low-voltage circuits are available for installation directly connected to the motor leads of induction motors.

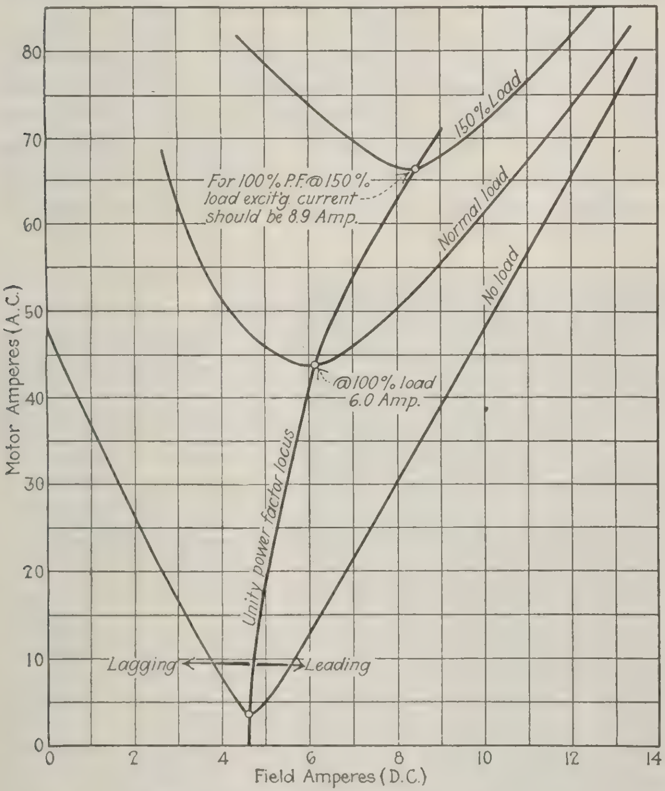


**Fig. 2—Use High Excitation to Get Good Power Factor**

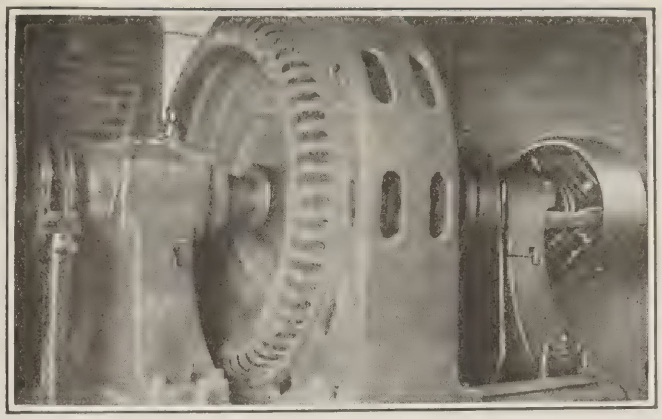
These are the V-curves of a 225-hp., 1,200-r.p.m., 2,300-volt synchronous motor. They show that it is necessary to excite the direct-current field about 8.5 amp. to carry 150 per cent load at unity power factor and 6 amp. to carry full load at unity power factor. Greater excitation than these amounts for the loads specified causes the motor to take leading current, lower excitation causes a lagging power factor.



**Synchronous Motor Drives a Large Mine Fan And Aids Power Factor Conditions**

The Buck Run Coal Co., near Minersville, Pa., uses this synchronous motor. It is connected to a large fan by a magnetic clutch. The motor cuts down wattless currents in the power system.

Present practice suggests that when the required leading reactive capacity for power factor correction is as large or larger than 300 kva. a synchronous motor should be given first consideration. It has the advantage over most other devices for this service in that it has inherent qualities which enable it to stabilize voltage fluctuations. It has an additional advantage in that it can be used in conjunction with automatic voltage controlling devices to maintain good voltage regulation. When so used the reactive current taken by the machine varies automatically to compensate for line voltage variations. Under high voltage conditions the synchronous motor may be operated to hold down the voltage, thus the machine may be easily adjusted to the needs of the circuit.

### APPLICATION IS LIMITED

The synchronous condenser is only applicable in large sizes for group power factor improvement. This is to some extent a disadvantage where small inductive machines operating from several banks of transformers cause poor power factor conditions. Under such a circumstance the poor power factor conditions are first allowed to accumulate and magnify before being corrected. This allows the heavy wattless currents to tie up transformer, alternator and line capacities which might otherwise be advantageously used. It also permits the circulating currents to cause poor voltage regulation and undesirable heating of conductors.

The synchronous condenser has greater losses than a static condenser and requires attendance unless it is made to function automatically, in which case the first cost is somewhat higher.

Group power factor correction even from the point of view of the static condenser being used for the purpose is often desirable because of low first cost. There are also conditions where the application of condensers of small capacity, either to individual motors or to small groups of motors prove most profitable. A complete line of static condensers conforming in sizes to the most popular induction motors is now available. These condensers are designed for direct application with 220,- 440- and 550-volt motors without intervening transformers or reactors, except where the capacity of

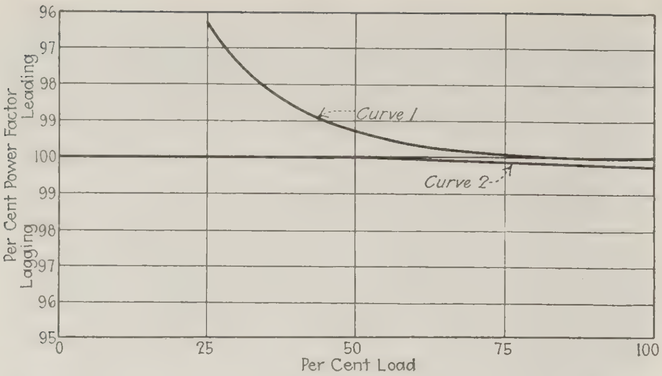


**Fig. 3—Good Results Are Obtained When Induction Motors Are Combined with Condensers**

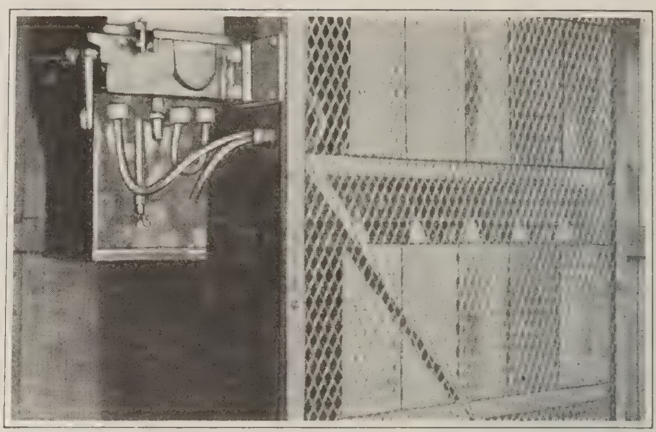
Curve 1 shows the power factor of the line resulting when an induction motor is supplied with a static condenser equal in capacity to that necessary to give 100 per cent power factor at full load. Curve 2 shows the results obtained when a static condenser equal in capacity to the reactive kilovolt-amperes of the motor at no load is used.



**A Static Condenser Outfit Which Quickly Paid for Itself**

One of the first static condenser installations at an anthracite mine was made by the Richmondale Coal Co. No synchronous equipment was in service at this mine and the static condenser quickly paid for itself by large reductions in the monthly power bills.

the condenser is large enough to make the transformer and high-voltage condenser more economical.

For 220-volt motors a 5-kva. outfit is about the largest economical unit suitable for direct connection to the motor leads. Condensers possibly as large as 30 kva. may be used directly connected to 440-volt circuits. When larger capacity condensers are required the fixed cost per kilovolt-ampere will be less with transformers and high-voltage condensers.

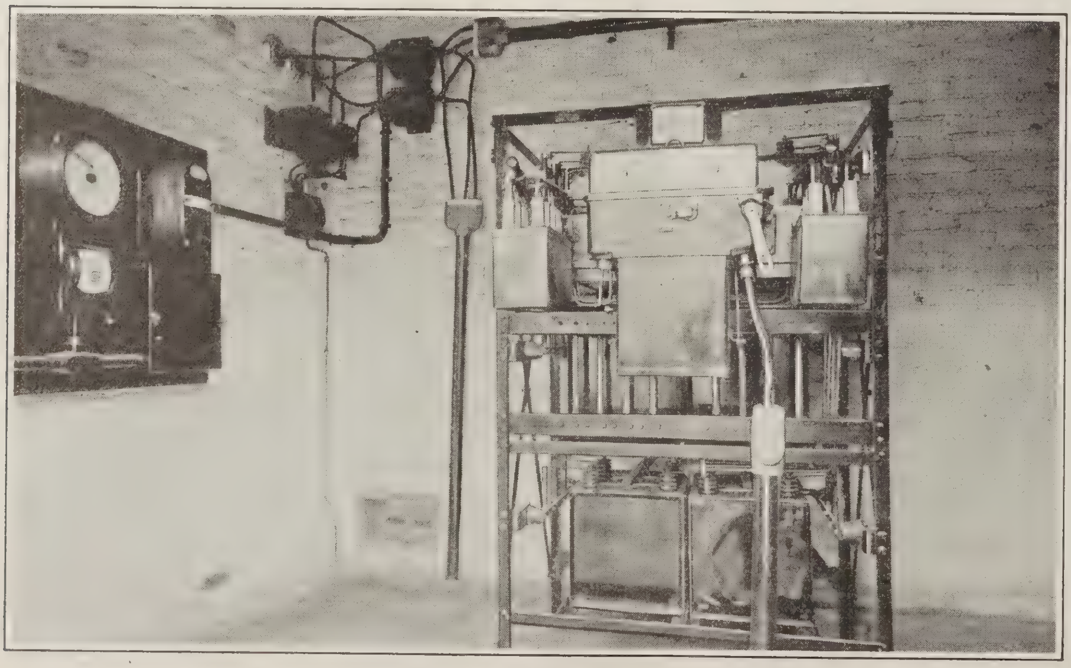
When determining the size condenser to use with an individual motor, much depends upon the characteristics of the motor load. Under some circumstances, especially when the motor operates continuously at full load the condenser may be much smaller than one applied with a motor driving a variable load. Fig. 3 indicates results obtained by the use of a static condenser equal in corrective capacity to the full load reactive kilovolt-amperes taken by an induction motor and also a static condenser equal in corrective capacity to the no load reactive kilovolt-amperes of the motor.

The curves show that when the motor is equipped with a condenser equal to the no load reactive kilovolt-amperes taken by an induction motor, the power factor varies from 0.9976 at full load to unity at no load. Such a condenser, therefore, gives entirely satisfactory results and is generally recommended.

Where condensers are to be used for power factor correction of a group of motors, the capacity of the unit depends upon the improvement desired. Obviously, the diversity factor of the load has a great influence upon the size condenser required.

Static condensers afford more flexible selection than synchronous condensers. A greater range of capacities is available. The location of a static condenser outfit requires no special foundations and the first cost is lower for small units. The losses are low and no or little attendance is necessary for their operation or maintenance.

The inherent characteristics of a static condenser are not such as to stabilize voltage, the leading corrective current which they supply increases or decreases with the voltage. However, it has been pointed out that because the lagging reactive current of induction motors and transformers varies with the voltage, this seemingly serious drawback to the static condenser is somewhat counterbalanced.



**Easy to Set Up**

Neat, compact and safe installations can be made with static condensers. Another advantage which they possess is that they require but little attendance. When floated on the line continuously during low load periods they will correct reactive induction current which was established during heavy inductive load periods, if the reactive current meter has no ratchet.

# Careful Investigation Shows Common Faults of Bits

## Shape, Clearance, Rake, Heat Treatment, Forging Method And Material All Important in Sharpening—Together They Fix Bit Usefulness

By **Joseph A. Blake, Jr.**
Chicago, Ill.

RECENT EXAMINATION of a large number of reports covering the performance of cutter chains disclosed the fact that most operating troubles resulted from defective bits. These reports extended over a period of nearly three years, included observations at more than sixty mines, and covered the products of several manufacturers. The high percentage of bit defects can hardly be considered as accidental; probably it reflects a generally prevalent condition. Certainly in many cases the efficiency of coal cutting machinery is greatly reduced by the use of poor bits.

Primarily a cutter bit is a roughing tool. It is designed to remove the maximum amount of material in a given time with the minimum consumption of power and at the lowest replacement cost. Its action, in general, is similar to that of a planer tool with the important difference that it must penetrate under the pressure of the feed which is continuous. Conditions of operation are trying. The cutting is usually done dry; there is little chance for the dissipation of heat; vibration is always present and variations in hardness and the presence of impurities in the coal expose the bits to sudden shocks which may be extremely severe.

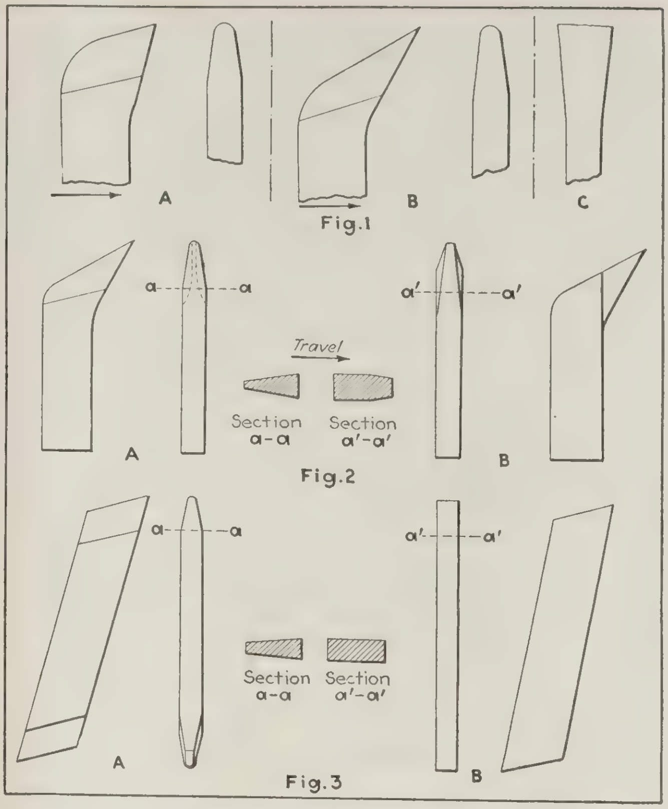
In spite of every precaution, therefore, occasional bit failures are to be expected. If the elementary principles governing the design and heat treatment of cutting tools are ignored, these failures may be so frequent that the cost of operation will be increased several fold. The diminished quantity of coal mined per shift is only one of the factors to be considered in this connection. Nine times out of ten, cutting with poor bits means an overloaded machine. Inevitably this causes frequent shut-downs and heavy expenditures for maintenance.

### POINTS OUT SIX BIT DEFECTS

The bit defects observed can be conveniently grouped under the following heads, the order being that of the frequency with which they occur: (1) Weak point, (2) incorrect clearance, (3) incorrect rake, (4) poor heat treatment, (5) bad forging, (6) use of an unsuitable steel.

Almost invariably a weak point is the result of too much rake or clearance or both, since any increase in these factors proportionately diminishes the included angle of the bit point. Bits having this defect may break under the stress of heavy cutting or as the result of shock. Also, since heat is removed from the cutting edge mainly by conduction, if the cross-section of the steel is small, this heat dissipation may not be sufficiently rapid to prevent a dangerous rise of temperature. Sharp points as, for example, the corners of the chisel bit, *C*, Fig. 1, are easily broken or damaged by over-heating and should, if possible, be avoided. A cutting edge without salients, like that of a round-nosed roughing tool, usually will stand up better under heavy duty than any other.

The rake and front clearance necessary for satisfactory performance depends to some extent upon local conditions. A bit without rake wears rapidly at the point and consumes unnecessary power. As the rake is increased, the force required to split off the chips diminishes, less power is required for cutting and the life of the tool is prolonged, assuming that enough metal is left to support the edge properly. Clearance should be sufficient to insure adequate penetration and avoid friction. More than is required to attain this result is unnecessary and may be harmful. The bits shown at *A*, Figs. 1 and 3, have a rake and front clearance of 15 deg. In the case of *B*, Fig. 1, these angles are both 30 deg. when the bit is not inclined. For a given contained angle, the relative rake and front clearance is governed by the inclination of the bit in the chain block. In the case of the bit illustrated at *A*, Fig. 3, which is formed without hook from a straight bar, the rake is fixed by this inclination and is not varied in sharpening. The double-ended construction, not possible with crooked bits, is a distinct advantage, since it is necessary only to reverse the bit to present a fresh point for cutting.



**Standard Shapes for Bits**

Each possesses advantages and disadvantages that are pointed out in this article in an effort to show mining men what this investigation proved.

Side clearance, often neglected, is highly important. The bits, *A*, in Figs. 2 and 3, will clear laterally and cut with little friction, whereas those shown at *B* will rub against the coal, consuming power needlessly. This fault also greatly increases the danger of overheating.

Heat treatment really begins with forging and the two operations may well be considered together. Overheating of carbon steel occurs frequently. This is always harmful and if carried beyond a certain point cannot be corrected by subsequent treatment. A safe rule is not to heat this steel above a bright red and to stop forging before it ceases to glow visibly in daylight. No instance of forging at too low a heat was noted, though it is easy to injure high carbon and many alloy steels in this way. One case of superficial decarbonization was reported. This may have been caused by frequent working. The same effect, however, can be produced by exposure of the hot metal to the direct action of the blast. In the latter case, cracks may also result from the chilling action of the air. This trouble can be avoided by the use of a deep fire. Where a large number of bits are handled, a suitably designed furnace is an economy. High-speed steel should not be forged below an orange heat, nor after it begins to stiffen noticeably.

With carbon steels, a water quench, followed by drawing, preferably in oil, will give the best results. If the bits are to be hardened all over and used without drawing oil is probably the safest quenching medium. In all cases where oil is used the bits should be cleaned after treatment. If this is not done, coal dust mixed with oil may become packed hard in the slots, making it difficult for the machine runners to set the bits. This trouble has been observed at several mines.

The greatest strength and durability of the cutting edge results when the steel is quenched from just above the critical range, sufficient time being allowed to permit it to become heated to this temperature all the way through. If the bits are left too long in the fire, or the temperature is too high, the structure will be coarse and weak. Quenching from the forging heat is never advisable. Carbon steel of approximately 120 points will be sufficiently hard for average cutting if heated to the proper temperature and allowed to cool in the air. Moderate care is necessary, however, when this method is used. If the bits are thrown on a damp floor, good results cannot be expected. They should be laid on a dry surface and shielded from cold air.

## Special Treatment for Alloy Steels

Alloy steels require special treatment. The instructions furnished by the maker for the handling of these products must be intelligently followed if good results are to be attained. Bits made from high-speed steel should be hardened at the point only. If they are hardened all over, the percentage of fracture in service will probably be high. In cold weather it is advisable to warm the steel before placing it in the fire.

In the selection of steels for cutter bits due regard should be paid both to local conditions and to the first cost of the material. An alloy steel may give better service than a carbon steel under certain circumstances yet be so expensive that its use is out of the question. The desirable qualities of any bit are: ability to withstand shock and abrasion, with sufficient hardness to permit the formation of a fairly keen, durable edge. Carbon steel of about 70 points, containing a small quantity of chromium and nickel, seems to be quite satisfactory in average cutting. It has the advantage of being relatively cheap.

Where greater hardness is required, steels of higher carbon content, up to 100 or 120 points are often used. Although such a steel frequently gives excellent service, it must be borne in mind that supersaturated carbon steels are comparatively brittle. Breakage is the commonest form of failure noted for this material. In several instances, shallow grooves made by the setscrew have been sufficient to determine the point of fracture. Burrs and indentations, should always be removed in sharpening. Besides being a source of weakness, such imperfections sometimes make it hard to set the bits and especially difficult to remove any that are broken. This increases the machine runner's temptation to operate with dead lugs. This steel is more expensive and harder to work than that first mentioned.

High-speed steel is seldom used in coal. Ability to stand high temperature without injury is its chief advantage. It is so expensive that its use, except under unusual circumstances, is not an economy.

Practically everything that has been said in regard to sharpening and heat treatment is generally applicable to cutting tools, and is known to every mechanic. Failure to apply the principles stated in the production of cutter bits probably arises from the type of labor and the facilities available at the average mine. Where the bits are sharpened by hand, the results obtained depend altogether on the skill of the blacksmith. Often his equipment is extremely limited, and if there is much bit sharpening to be done, uniformity of shape and temper can scarcely be expected. Die forging makes it easy to turn out correctly shaped bits with a large saving in time over hand methods but does not affect the problem of heat treatment. Dies are expensive, and their life is comparatively short. All bits produced by a defective die will be badly formed. Because of their high cost, and the time saved, as compared with hand work, there is a tendency to keep in service dies that ought to be discarded.

Finishing bits by grinding after they have been forged, in order to obtain correct and uniform shape, has been tried at a few mines with apparent success. Unquestionably, a better edge can be made by grinding than in any other way. A bit so designed that it could be shaped by a simple grinding operation from a length of bar stock without forging and that could be repeatedly sharpened in the same way, would be almost ideal. This method would eliminate the uncertainty of heat treatment.

Just as in the case of a lathe or planer, the efficiency of a mining machine cannot be greater than that of the cutting tools with which it is armed. Excellence of mechanical design and construction is useless if the bits employed are composed of poor material or are wrongly shaped. The majority of mines might well pay more attention to the forming, sharpening and tempering of their bits than they do at present.

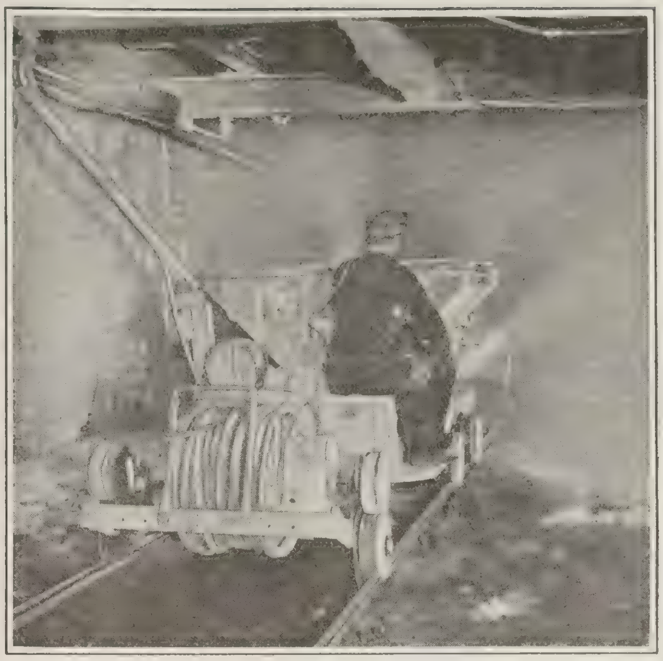
**A Coal Miner's Home in the West**

The best home in Rock Springs, Wyo., is owned by a Tyrolese miner, John Schlachter, who mines coal at Winton, a coal town nearby, operated by the Union Pacific Coal Co. Schlachter is a skillful stone cutter, mason and builder. Most of the stone work he did himself, using the castellated style so general in his home country. All the house needs is a little grass on its lawn, but to grow that in Rock Springs requires an infinitude of coaxing.

# Rock Dusting Reduces Danger and Lowers Compensation Rating

## All Passages, Even to Rooms, Thoroughly Dusted—Machine Delivery Nozzles Oscillate, Effectively Coating Surfaces

**By Alphonse F. Brosky**
Assistant Editor, *Coal Age*,
Pittsburgh, Pa.



IT IS PROBABLE that the Harmar mine of the Consumers Mining Co., a subsidiary of the Wheeling Steel Corporation, is as thoroughly rock dusted as any coal operation in the United States. This mine is located at Harmarville, Pa., a few miles from the city limits of Pittsburgh. It was the first coal operation in Pennsylvania to be completely treated with inert dust according to the judgment of the state Compensation Rating and Inspection Bureau, for the bureau granted to this company the first credit in compensation rating amounting to 10c. for rock dusting, at the same time removing the charge of 5c. against Item 85, pertaining to a dry and dusty mine.

Standing haulage entries were cleaned up before rock dust was applied for the first time. In the primary application 5.85 lb. of dust was spread per linear foot of entry. Rock dust is applied by hand to the top of all beam roof supports. As places (including rooms) are driven up, rock dust is periodically laid, each such extension reaching to the face. All return airways have been dusted by hand—two sacks or 160 lb. of dust being applied to every 25 lin.ft. These passages are further protected against the dangers of coal dust by a secondary defense consisting of 107 barriers installed at intervals of 500 ft. Each barrier holds 640 lb. of dust. It is now the practice to rock dust by machine the back entries as they are advanced, before the track is torn out.

Thus far the company has applied 483 tons of rock dust to about 25 miles of entries and rooms. The practice was started Oct. 1, 1924, and the initial dusting was completed on Feb. 19, 1925. In that period of five months $2,874.52 was spent for rock dusting and 185,901 tons of coal produced so that the cost of the initial treatment per ton of coal amounted to 1.54c. The expense of rock dusting extension and maintenance per ton at the present time is 0.9c. the dust being applied at the rate of 5.85 lb. per linear foot. The cost should be about 0.5c. per ton of coal under similar conditions if only 3 lb. of dust per linear foot were applied.

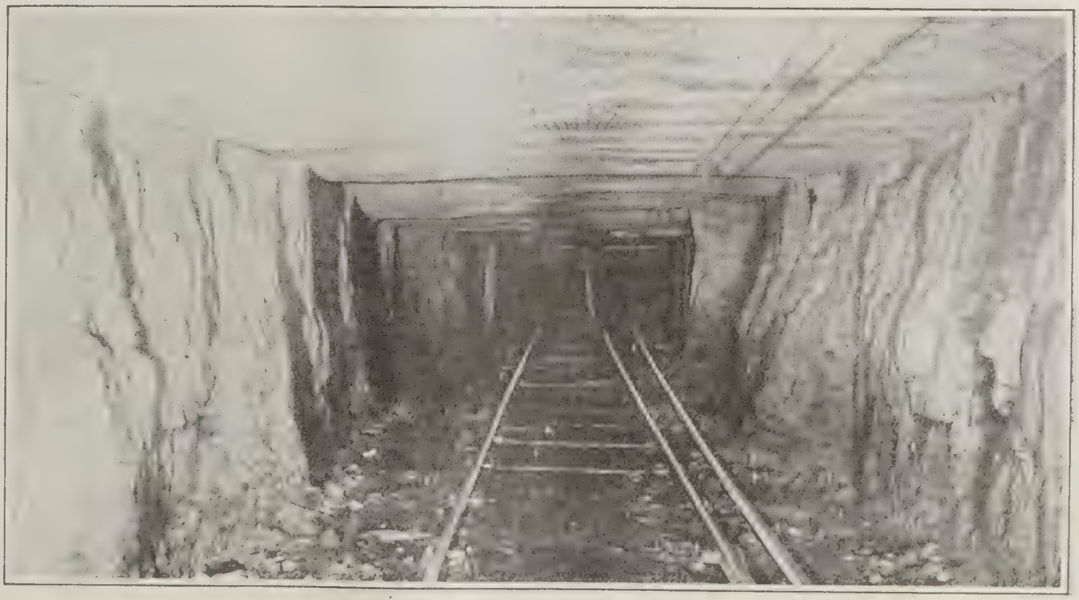
An application of 3 lb. of rock dust per linear foot of passage treated is not enough in the Thick Freeport bed. A 3-lb. coat is too deeply embedded in the cleats and crevices of the coal to be dislodged instantaneously into a cloud. This fact was determined experimentally by applying a jet of air under 80-lb. pressure first to a 3-lb. coat and then to a 5.85-lb. coat. The dust of

---

In the headpiece accompanying this article may be seen the Harmar mine duster in action. The operative is not enveloped in the cloud of dust produced but in his position on the rear of the machine breathes pure air while controlling the movements of the duster. Rocking nozzles direct the material discharged to the roof and ribs, effectively coating them.

**This Entry Is Well Dusted**

Approximately 25 miles of entries have been treated with rock dust in this mine, which was the first to receive a reduced compensation rate by virtue of this protection. This entry is a main aircourse near the face. The smoothness of roof and the absence of timbers is an indication of topcutting. The cross-section of this entry appears "upside down," that is it is larger at the top than at the bottom. This is because of the top cutting. Ribs sloping inward will, naturally, gather more dust.



**Rock-Dusted Face of an Entry**

The face of this entry is only about 30 ft. inby of the last breakthrough, yet it is thoroughly rock dusted. Note how the topcutting makes a dangerous roof safe. The man on the left is the safety boss who is in the act of showing the miner where to drill his shot holes in the face.

the lighter coat was only partially stirred up by the air jet whereas that in the heavier application immediately formed into a dense cloud. The point is that a certain quantity of rock dust must be applied to smooth out the recesses in the coal. The filling-in dust is not nearly so effective as that which lies over it.

It is unwise to apply a second coat to an initial layer that is covered with coal dust, as on a shaft bottom. The coal dust will bind the two coats together only while the mine is dry. It forms a plane of weakness from which the second coat separates, falling to the floor, after the dust becomes moist. This was experienced in the Harmar mine. The initial coat should be removed by air or brushing, if necessary, before the fresh coat is applied.

Light, fine dust is not suitable for treating haulage roads. Such material will not stick securely to the ribs and roof and much of it travels with the air, to settle finally on the bottom, where it is picked up and swirled into a cloud by passing trips. But this dust is well-suited for back-entry use if its distribution by the mine air has any distinct value.

High-pressure dusting tends to produce a dense coat whereas low-pressure application results in a fluffy coat. This company prefers the latter, believing it to be the more easily blown into a cloud.

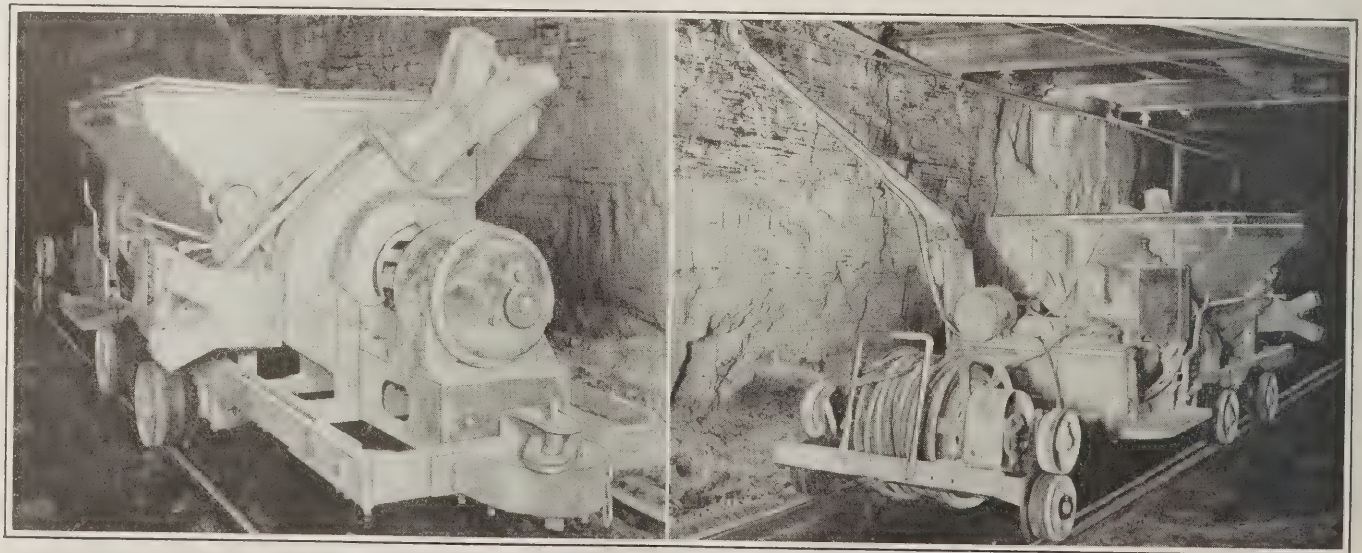
In mines where the roof is bad, as in the Harmar operation, shelf and even trough barriers are maintained in back entries only with difficulty and at high cost because of frequent falls of roof which dislodge these barriers.

Animal haulage is a big producer of coal dust. Until recently two horses were used for gathering in a small isolated section of the Harmar mine. The roadways were cleaned and then dusted. In a few days' time so much spillage from the mine cars was pulverized to such a degree, and so effectually mixed with the rock dust between the rails, as to make the two dusts appear as one. Even on the undisturbed rock dust in the clear a readily perceptible blanket of coal dust had settled.

High-silica dust and its ill effects on the human respiratory organs are almost as readily detected by the practical mining man as by the scientist in the laboratory. A high content of silica can be detected by the reflection of light from its particles. Workmen will complain about the effects of a high-silica dust without knowing that the content of that material in the dust inhaled is high. Further, a high-silica dust will not stick well to the mine surfaces but tends to drop to the floor. These manifestations were noted during the application of one lot of dust containing 7 per cent of silica. The Harmar mine uses a dust of a fineness such that all will pass through a 20-mesh and 75 per cent through a 200-mesh screen. It also must otherwise meet Bureau of Mines requirements.

A rock dusting machine has been developed at the Harmar mine, of the low-pressure type, which applies dust automatically to ribs and roof. One man controls the feed and speed of travel of this device from the rear end. He is in the clear of the dust cloud produced and is assisted by a helper.

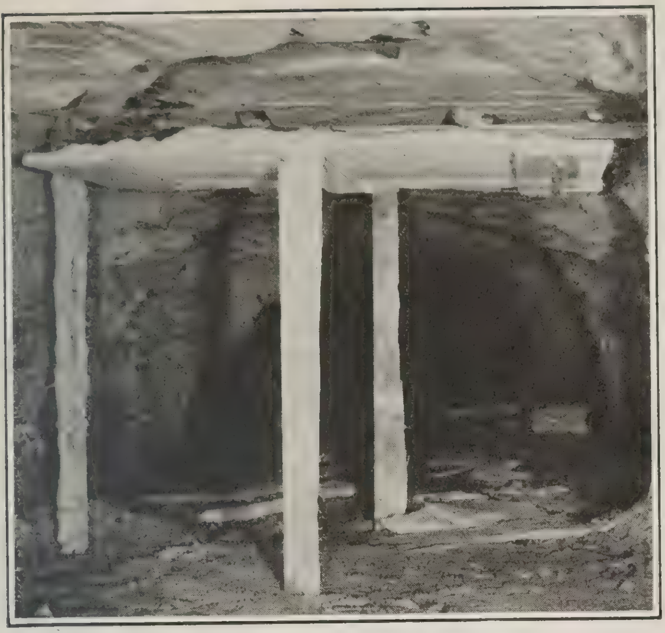
A front view of this duster is shown in one of the accompanying illustrations. The overall height of the machine, as measured from the rail to the tips of rocking nozzles when these are in their highest position, is 52 in. The elevation of the top of the storage bin



**Fore and Aft on the Harmar Mine Dusting Machine**

The front of duster with its rocking nozzles is at the left. Dust is fed into a two-compartment blower and discharged into the atmosphere through double or forked nozzles, which rock up and down with the blower housing through an angle of 45 deg. The dust is thus effectively distributed to all of the mine surfaces.

The rear of duster showing cable reel is pictured at the right. This reel, which is of the friction type coiling 500 ft. of No. 6 duplex cable, enables the machine to reach the faces of rooms and advancing entries. Speed of travel of this duster is controlled through resistance.



**Double-Hinged Door Rock-Dust Barrier**

In the back entries of the Harmar mine 107 barriers of the type here shown have been erected. Each of these has been charged with 640 lb. of rock dust. They are hard to maintain because of roof falls. Note the freshly fallen slabs of slate at the foot of this barrier.

**A Rock-Dusted Room**

Rooms as well as entries are dusted in the Harmar mine; in fact the management believes that the dusting of room and entry falls is more important than the treatment of entries themselves, for it is at these places that most explosions originate. The roof here shown is much better than the average found in this mine.

above the rail is 45 in. This container has a capacity of 3,000 lb. of dust. It is covered with a wooden lid, not to prevent back pressure (for there is none) from disturbing the dust within it but to forestall damage to the feeder inside the bin in case of a roof fall.

The feeder is a 4-in. screw which so revolves as to force dust into a blower. Above it rotates a shaft carrying projecting arms which serve to break any arching of dust above the screw. The dust is fed through a pipe into a two-compartment blower. This pipe is provided with two slot regulators, by the opening or closing of which the feed may be equalized between the two compartments. By the blower the dust is thoroughly mixed with the air and carried to two outlets, one on the right and the other on the left side of the fan housing.

Telescoping over and projecting from these two outlets are two branched ducts 135 deg. apart. Thus a split nozzle, in the shape of a Y is formed. The dust is applied to ribs and roof by a rocking motion of the blower housing and the attached double-outlet ducts, through an angular displacement of 45 deg.

The blower is direct-driven by a 5-hp., dustproof motor at a speed of 1,700 r.p.m. The fan and motor armature are mounted on a single shaft in a triple ball-bearing suspension, doing away with undue vibration and heating.

The rocking motion is imparted to the nozzles by a crank, connecting rod and rocker arm arrangement, as shown in one illustration. On the side of the hopper and parallel with its major axis is a shaft which is chain-driven from the screw-feed shaft. This drives a pair of gears on one of which is mounted a crank. A connecting rod joins this crank to the short arm of a bell crank pivoted at the knuckle. The long arm of this bell crank rocks the blower housing and nozzles back and forth through an arc of 45 deg.

The feed-screw shaft is driven by a chain from a 1-hp. dustproof motor. This shaft also carries a pinion engaging with a gear which drives the agitator.

A 6-hp. motor propels this machine which will haul two or three cars of dust if desired. The drive is by a 6 to 1 reduction from the motor to a countershaft and by a 3 to 1 reduction from there to the axles of the truck. By resistance control this machine can be made to travel at speeds ranging from 6 miles to 660 ft. per hour. As may be seen in one of the accompanying illustrations a mining-machine type of friction-driven reel capable of holding 500 ft. of No. 6 duplex cable may be attached to the rear of this machine.

Two men in 8 hr. can apply 125 to 150 sacks (80 lb. each) of rock dust, including the time required for back-tracking and filling the hopper.

---

## An Explanation

George R. Pratt, Alberta government fuel engineer, whose paper before the Canadian Mining Institute was abstracted for an article on page 700 of the Nov. 19 issue of *Coal Age* under the headline "Beating Anthracite Is Difficult in Winnipeg," feels that the article misinterpreted what he said. He has wired *Coal Age* this message: "What we have done to take the anthracite market in Winnipeg is common knowledge to Institute members, consequently it was not stressed in my paper. This led to your misconception as shown by the title. The intention of the paper was to show what must be done to stabilize the industry. Six years ago Winnipeg fuel was 90 per cent anthracite; three years ago 10 per cent. Now we ignore anthracite as a competitor. Alberta competition comes from soft coal from other sources."

There was no misconception of Mr. Pratt's intentions by the editors. Because so large a part of the United States is now trying to "beat anthracite" with soft coal—and with some success—only those parts of Mr. Pratt's paper which dwelt upon Alberta's experience in this regard were used. It is regretted that there was not space available for printing all of Mr. Pratt's paper.—Editor.

# Million-Dollar Tunnel Puts Mine Nearer Seattle

### Mile-Long Drift Under Cedar Mountain Gives Old Black Diamond Operation an Outlet Only 17 Miles from City for 2,000-Ton Output

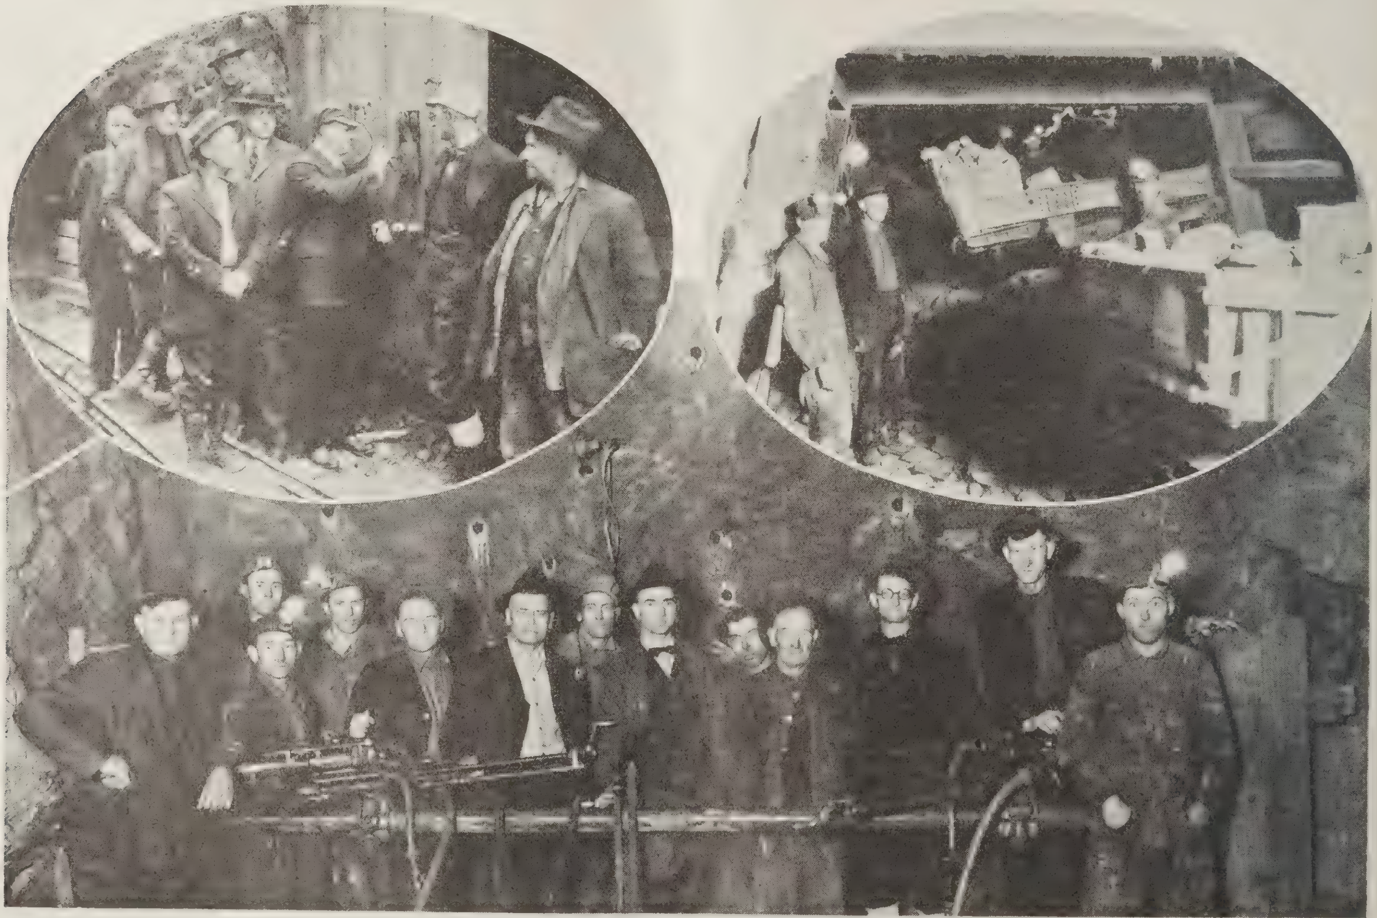
THE LAST PIECE OR ROCK separating the ends of the Pacific Coast Coal Co.'s tunnel under Cedar Mountain was blasted through on Oct. 16, thus completing an underground passage over a mile in length through which coal from the new Black Diamond mine will be delivered to the tipple on the Pacific Coast R.R. Completion of this tunnel—the two ends met fairly—is an engineering feat of no mean importance. One end of this passage was driven from daylight while the other started in the mine workings on the other side of the mountain. Junction of the two sections was effected almost exactly midway between their starting points. The project cost a million dollars but it brings out coal much cheaper and in better condition than that from the company's older operation at Black Diamond while reducing the distance from the mine to Seattle from 33 miles to 17 miles.

In the driving of this tunnel many formidable difficulties were encountered and overcome. Thus the course of this passage lay through a fault of considerable width and displacement, also through the buried bed of an ancient river, now several hundred feet beneath the surface and filled with loose material and detritus. These difficulties, however, were all surmounted and the tunnel pushed to completion.

The new Black Diamond mine lies in the McKay coal bed. Its extent is such that it is calculated that 2,000 tons can be extracted each day for 50 years before the mine will be worked out. Modern equipment only is installed and although the delivery tunnel just completed was expensive it is estimated that the cost of coal from this mine will be much less than from others in its vicinity. Location of the tipple within 17 miles of the business center of Seattle, Wash., assures an excellent market.

## Expect More Lump

The coal produced will be of the same grade as that mined at the company's older Black Diamond operation, which will be worked out in the course of a few more years. A tipple and screening plant at the new opening is now under process of construction. It is believed that a much larger percentage of lump will be realized from the new mine than was obtained from the older one. This will be because of the lesser thickness of overburden above the new operation and the consequent



**Bringing the Mine to the Tipple Cuts Cost of Coal**

The large illustration shows the face of the last barrier, 9 ft. thick, the blasting down of which joined the two sections or ends of the tunnel under Cedar Mountain. The two sections of the underground passageway met almost exactly, thus completing a direct and unobstructed passage between the mine and the tipple on the opposite side of the mountain, and one that will be entirely unaffected by weather.

In the illustration in the upper left-hand corner N. D. Moore, vice-president of the Pacific Coast Coal Co., surrounded by other officials is shown throwing the switch that fired the loading in the last barrier of the tunnel. Although this barrier was half a mile away, it was completely shattered by the closure of this switch on the surface.

In the illustration in the upper right-hand corner is shown one of the little Hoar shovels cleaning up the remains of the last barrier and uniting the two halves of the haulage tunnel. In driving this passage these little shovels gave an excellent account of themselves and will now be put to work in loading coal cars in the mine proper, thus cheapening production.

lighter pressure to which the coal face is subjected. In the older mine neither undercutting nor explosives are necessary, the coal coming away from the face, sometimes with appreciable force, under slight action of the miner's pick. This condition is not conducive to a yield of large coal.

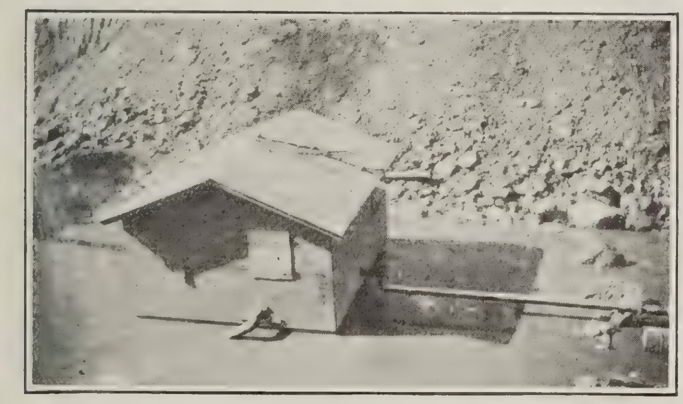
In the newer operation, on the other hand, both undercutting and explosives will be employed as the depth of cover encountered is only a fraction of that found in the older mine. A goodly percentage of lump can thus be obtained. The modern screening and preparation equipment installed on the new tipple will enable the company to take full advantage of this fact and market a product of excellent quality and grade.

In this operation modern methods and equipment will not be confined to the tipple and preparation plant. The mine itself will be electrically lighted, at least along the main gangways. Electric locomotives will be employed for haulage and revolving mechanical shovels will be used in loading out the coal. Machines of this kind gave an excellent account of themselves in mucking operations in the tunnel.

# Floating Pump Scow Quickly Drains Surface Pit

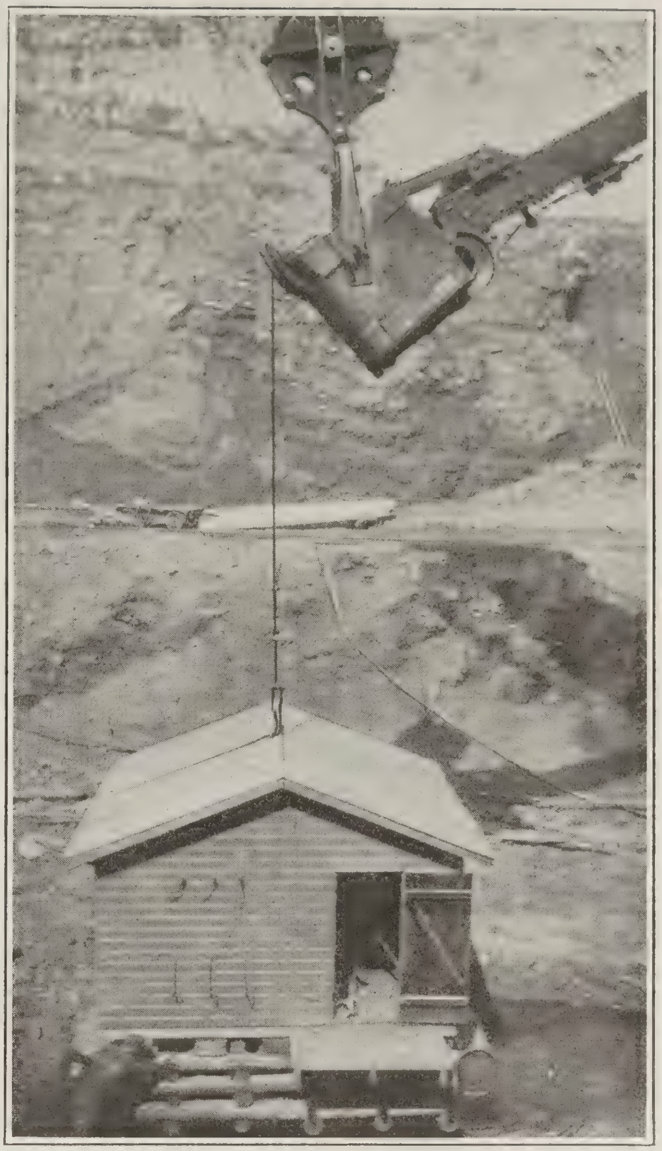
### Equipment Assembled with Small Cost Put in Operation in Minnesota Mine—Easily Moved About by Big Pit Shovel

An inexpensive equipment to keep an open pit free from water and to prevent any danger of submerging the pumping equipment, says L. C. Moore in *Enigneering and Mining Journal-Press*, was designed and put into service at the Boeing mine, Hibbing, Minn. Eight-inch poles, 16 ft. long, were used in the construction of a square crib, openings being left to fit 50-gal. empty, steel oil barrels. Thirty-four barrels were placed in the cribbing and fourteen additional barrels were lashed to the sides with discarded ⅝-in. steel cable. Timbers 8x16 in. in section were bolted on top to support the pumps, and a pump house, built in sections, was set on the top of the scow thus formed. Two 1,000-g.p.m. centrifugal pumps, 175-ft. and 350-ft. head respectively were available and were placed on the scow. A 2,300-volt, three-conductor, steel-armored power cable connected the pump motors to the transmission line.



**Pumping Station Afloat in the Pit**

The discharge piping from this station was provided with swing joints permitting a variation of several feet in the pumping level. When the pit became flooded from a cloudburst this station pumped the water out in a few hours and stranded itself.



**Swinging Pump House Into Place**

Sectional construction was employed in building the pump house and the raft or scow upon which it rests is of what might be termed a "semi-knockdown" type, that is, when not in use the various pieces may be separated and stored or put into other service. The whole plant can be moved about in the pit by the stripping shovel.

As the pumps operated under a head of only 30 ft., a gate valve on the discharge line was necessary to prevent overloading the motors. The discharge line was provided with swing joints admitting of a variation of 12 ft. in the elevation of the scow. The complete outfit weighed eight tons. It was built upon a flat car and was shifted by means of the 350-ton shovel used in the pit. Four ⅝-in. cables were attached to the corners and connected to a clevis at the center. A short wire rope sling was attached, the other end being looped over the bucket teeth.

The equipment was tested out in August when a small cloudburst filled the pit sufficiently to float the scow. The shovel trucks were submerged but in seven hours the water was out and the shovel at work. The outfit, as designed, can be dismantled readily, the equipment and sectional pump house can be used separately and the oil barrels after cleaning and painting are ready for further service. The timber employed in the construction of the scow had been discarded and was of little value.

# News Of the Industry

## Pinchot Still Central Figure in Hard-Coal Controversy; Operators Declare for "Stronger Union"

The Pinchot plan for settling the anthracite strike, submitted by the Governor of Pennsylvania at Harrisburg on Nov. 28, is still the storm center in the hard-coal situation. The business interests of the anthracite region who tried to stop the calling of the strike of Sept. 1 are again active in efforts to bring the miners and the operators together. Union officials are ballyhooing for the Pinchot program and are endeavoring to persuade the public that the operators' rejection of the Governor's eleven points—one of which (that providing for an immediate resumption of mining) the union leaders themselves kicked into the discard—is proof of the employers' contempt for the consumers' necessities. The mine owners, on the other hand, have been busy reiterating the reasons for their position and, as the details of the Pinchot program become better understood, public opinion is again lining up behind the operators.

That the rejection of the Governor's proposals has closed the door to negotiations was vigorously denied by Major W. W. Inglis, spokesman for the producers. On the contrary, he asserted, the Pinchot plan had been turned down because it did not promise permanent peace and justice. The cry of the miners that the operators were leagued together in a conspiracy to wreck the union was met with the statement that the employers would like to see an even stronger labor organization than the one now functioning.

### Operators Are Receptive

"The door has not been closed to negotiations," said Major Inglis. "Quite the contrary. We are anxious to secure a real and lasting peace, and negotiations to that end cannot be begun too quickly. The difficulty with the Pinchot proposals is that they do not pave the way even for peace, much less a lasting one.

"As to arbitration, we are willing to accept any plan or scheme that will provide for reasonable, fair and impartial determination of the conditions and make awards in accordance with such determination. Governor Pinchot has not proposed arbitration. What he proposed is to be the index to wages and prices for five years. No person knows what changes will come in that time and no sane business man will make a contract that he is not certain he can keep. The contract proposed would in the end be bad for all and for the men most of all.

"There is no desire on the part of the operators to break down or weaken the union. We want a strong union, even a stronger one than we now have. The trouble is the union is not strong enough. It is strong politically but not constructively. Absolutely the last thing we would wish would be a return to the conditions existing prior to the coming of the union."

Governor Pinchot accused the operators of rejecting peace for industrial war, but still expressed the hope that his program eventually would be accepted. Something of this last hope seemed to be in the minds of the scale committee of the miners as its members left Harrisburg. President Lewis, who seized upon the new deadlock as an opportunity to revisit his family, was less bellicose than usual in his condemnation of his opponents. "The fight is now between the public and the operators," was his statement before departing for Springfield, Ill.

### Father Curran Still Active

Other figures in the controversy were less restrained in their comments. Thomas Kennedy, international secretary-treasurer of the United Mine Workers, declared that the operators "have now come out in the open and are out to smash the union and to force wage reductions." Father Curran, of Wilkes-Barre, again criticized the attitude of the operators, but renewed his efforts to win acceptance to his proposal for a 5-per cent increase and a modified check-off. Some of the local unions in the region, particularly in District No. 1, demanded that the maintenance men be withdrawn in reprisal for the operators' refusal to accept the Pinchot terms. Certain workers in the southern end of the field also took a similar stand, but the higher officials of the organization have declined to sanction the demand.

First reactions to the operators' rejection among the men were favorable to the union. Morale was strengthened. Underneath, however, were signs of growing dissatisfaction with the continued suspension and despair over shattered hopes. Observers in the region noted a more intensive program of economy, the disappearance of the holiday spirit with which the strike was welcomed. The movies so far have survived the general depression, but merchants in the region are gloomy because of the marked curtailment in buying and the outlook for a slim Christmas business.

These unfavorable prospects spurred the business interests of the anthracite region to fresh efforts to effect a resumption of mining. The Chambers of Commerce of Scranton, Wilkes-Barre and Hazleton took the lead in this movement. The Pinchot program, reported to have had their indorsement at the time it was submitted to the operators, was scored and the report of indorsement repudiated. Commercial interests denounced the program as a political maneuver designed to further the Senatorial aspirations of the Governor. The immediate upshot of this "rebellion" against political interference was the invitation of the Governor to the business leaders to confer with him in Harrisburg on Tuesday of this week.

### Round-Robin Advises Industry

Establishment of a "continuing joint agency" to study the underlying "economic and technical facts" of the industry was offered as the only permanent solution of the troubles besetting anthracite, in a round-robin to Major Inglis and Mr. Lewis signed by forty-one engineers and economists at a meeting in New York on Dec. 4. The signatories, including a number of well-known college professors and past presidents of engineering societies, declared their belief that no agreement will insure continuity of production and distribution in the future which did not set up the agency suggested.

"Observation and experience convince us," asserted the forty-one, "that joint effort on the part of management and workers in improving methods of production and distribution can increase wages and lift and stabilize earnings at the same time that they lower the price to the consumer. The constructive results of such joint effort would, we believe, be of far larger importance both to you and to the consumers of anthracite than the mere temporary settlement of symptomatic grievances. We submit that the present price of anthracite and the recurring interruptions to its production constitute a challenge to you jointly to grapple with these fundamental problems of economic and technical organization."

"We entirely agree," replied the Anthracite Operators' Conference on Dec. 7, "that so far as our industry is concerned, the need is for 'constructive consideration of the underlying economic and technical facts by which all questions of wages, working conditions and earnings must, in the end, be determined.'

"The basis of consideration you propose, namely, one of facts, and which will take into account all economic, industrial and commercial factors, has our hearty assent. The ideas you express are upheld by the findings of the U. S. Coal Commission which said in effect that what was needed was more dependence on facts and less on force. It is for the maintenance of this principle that we have been contending from the beginning of the present dispute."

Although on the surface operators and miners are still far apart on the key issue of arbitration, there are some who privately take a more optimistic view of the situation than they are willing to acknowledge publicly. They feel that the men themselves are anxious to get back to work and that the union leaders would like to find a way out of a tight corner. In support of this view they point out that the union in its dubious acceptance of the Pinchot program agreed to a limited arbitration of wage issues despite earlier fulminations against anything smacking of such determination. They are confident that the more the public comes to understand that the operators are willing to submit the whole dispute to unrestricted arbitration, the less the union will be able to resist the pressure for settlement.

The greatest danger spot is Congress. Senator Borah undoubtedly will lean upon the anthracite strike to support his plea for favorable consideration of his legislative program on coal. Senator Oddie may be expected to do likewise. Radicals like Representative Berger of Wisconsin will see in the situation an opportunity to press their doctrines; other members of Congress who are disposed to make political capital out of the suspension will not be silent.

## Jersey Names Coal Board

A coal commission of twelve members was appointed last week by the New Jersey State Chamber of Commerce to act to protect the fuel requirements of the state under the conditions created by the anthracite strike. The members of the commission are:

James Wilson, Paterson (chairman), vice-president, State Chamber of Commerce, Paterson Coal Dealers' Association; James C. Tattersall, Trenton, director, National Retail Coal Merchants' Association; C. B. Ace, Hoboken, president, Hudson Coal Credit Association; Richard McAllister, Jr., Camden, representing coal dealers in southern New Jersey; A. E. Broadbent, Newark, acting secretary, New Jersey Coal Dealers' Association; F. C. Conkey, Elizabeth, acting secretary, Central New Jersey Coal Exchange; J. J. Mantell, vice-president, Erie R.R.; R. M. White, superintendent, Delaware, Lackawanna & Western R.R.; C. H. Stine, general manager, Central R.R. of New Jersey; F. H. Moser, coal freight agent, Lehigh Valley R.R.; Frank A. Keys, coal freight agent, Baltimore & Ohio R.R., and J. W. Warwick, special operating agent, Pennsylvania R.R.

## *Act on Commission Report to Meet Emergencies, Says Coolidge*

In his message to Congress, delivered at Washington Dec. 8, President Coolidge made the following comment and recommendations in regard to coal:

"The perennial conflict in the coal industry is still going on to the great detriment of the wage earners, the owners, and especially to the public. With deposits of coal in this country capable of supplying its needs for hundreds of years, inability to manage and control this great resource for the benefit of all concerned is very close to a national economic failure. It has been the subject of repeated investigation and reiterated recommendation. Yet the industry seems never to have accepted modern methods of adjusting differences between employers and employees. The industry could serve the public much better and become subject to a much more effective method of control if regional consolidations and more freedom in the formation of marketing associations, under the supervision of the Department of Commerce, were permitted.

"At the present time the national government has little or no authority to deal with this vital necessity of the life of the country. It has permitted itself to remain so powerless that its only attitude must be humble supplication. Authority should be lodged with the President and the departments of Commerce and Labor, giving them power to deal with an emergency. They should be able to appoint temporary boards with authority to call for witnesses and documents, conciliate differences, encourage arbitration, and in case of threatened scarcity exercise control over distribution. Making the facts public under these circumstances through a statement from an authoritative source would be of great public benefit. The report of the last coal commission should be brought forward, reconsidered, and acted upon."

## Says Real Secret of Safety Is Co-operation

Phil Penna, secretary of the Indiana Coal Operators' Association, expressed the predominating thought of the safety conference called recently by the Indiana mining board when at the end of the meeting he said: "The sooner operators and miners forget politics and their differences and go into co-operative efforts in safety promotion the better for all of us. If safety precautions and safe practices cannot be enforced by co-operation, it can't be done."

More than a score of delegates representing coal mine operators, miners, insurance companies, the state department and the U. S. Bureau of Mines attended the meeting. William Johnson, president of the state mining board, presided at the conference.

Francis Feehan, mine safety commissioner of the U. S. Bureau of Mines, explained what had been accomplished along safety promotion as a result of co-operation in several districts around Pittsburgh. He said some states had laws regulating the miners in taking proper precautionary measures for their own safety that he would recommend for Indiana. He explained the suspension system now employed in some fields. He also said that Indiana mines were violating one of the most necessary precautionary measures in continuing to use the open-flame lamp instead of the electric torch.

J. H. Gritner of Illinois, representing the Associated Insurance Companies, in summing up the results of the conference, said it was evident that co-operation was the fundamental need, that there was an obvious need for law revision in Indiana and that supervision should be clothed with the authority to inflicting penalties.

## Court Remands Utah Land Case to Trial

Carbon County, Utah, has been adjudged not implicated in the proceedings brought by the government to recover title to coal deposits assigned to individuals through alleged fraudulent means. The decision was rendered by the U. S. Court of Appeals sitting at St. Louis. The Carbon County Land Co. made use of the state as a mere conduit through which the lands were fraudulently acquired, the court decided. It is believed that the case will go to the U. S. Supreme Court for final decision.

The federal government brought suit to try to disprove title of the Carbon County Land Co. and the Independent Coal & Coke Co., and the defendants moved for a non-suit on the ground that the government was barred by the statute of limitations. Federal Judge Johnson upheld the plea for a non-suit, and the Circuit Court of Appeals has now reversed his decision, remanding the case for trial and requiring the defendants to answer. It is said that the importance of the case is found in Utah's fight against the federal government's policy of centralizing power and depriving the state of valuable land granted under the enabling act. The land grants were selected by the state between 1900 and 1904 and were classified at that time as non-mineral. The classification was based on the ruling of the Interior Department which was to the effect that no coal land was mineral in character unless coal in commercial quantities was exposed in each 40-acre tract. This classification is alleged to have been approved by the Secretary of the Interior.

# Hard-Coal Control in Borah Bill Opposed by New York Business Men

Opposition to government control of anthracite such as Senator Borah is expected to propose at the present session of Congress was registered Dec. 3 by the New York State Chamber of Commerce at a monthly meeting in New York. This action was taken without discussion, beyond a few remarks by former Senator Calder, who wished that the Chamber would propose something constructive looking toward the correction of coal ills instead of merely opposing legislation. Senator Calder, however, is against the Borah bill.

The Chamber's committee on internal trade and improvements, in its report, summarized the Borah bill—as it was once before prepared—and the arguments against it thus:

The Borah bill creates an anthracite coal division of the Interstate Commerce Commission. Its many provisions comprise 633 lines, indicating the great details into which it goes and the endless amount of interference with the anthracite industry.

We consider this measure one of the most dangerous ever introduced into Congress. It goes farther toward putting the government into business than anything heretofore attempted. It not only declared "the production and distribution of anthracite coal are services indispensable to the health, comfort and welfare of the people of the United States," which is not true, but it proceeds to convict everyone connected with the industry through its assertion that these services "are subject to exorbitant charges and arbitrary control."

This measure not only gives the division of the Interstate Commerce Commission which it creates the right to investigate the ownership and title of the mines, but also "the persons connected with the anthracite coal industry directly and indirectly." The opportunities under this inquisition probably are without precedent in this country. It gives the Commission power to compel persons engaged in commerce in anthracite coal to secure licenses from it and to suspend or revoke such licenses. In other words, it may say just who shall and who shall not engage in the coal business. It is to prescribe standards of weight, size and purity of anthracite and has even the power to issue mandatory orders with regard to the rents and royalties paid by operators and the prices for which coal is to be sold.

A point which requires special emphasis is that which authorizes the coal commission to serve as part of the main Interstate Commerce Commission in the hearing and determination of all cases involving anthracite freight rates, car distribution to anthracite mines and regulations of carriers affecting the anthracite coal industry.

### Opposes Super-Regulation

Under this provision, the coal product of only eight counties in the State of Pennsylvania would be singled out for a closer measure of government scrutiny and interference than any other industry in the country. The railroads which serve this industry would have imposed upon them a super-regulation far in excess of that of carriers which do not handle anthracite as a major part of their traffic. This super-regulation would compel the affected railroads to make a volume of special reports, as the Commission may require, regarding their "organization, business, conduct, practices, management and relations to other persons"

Obviously the adoption of any legislation of the sort proposed must necessarily serve to make a continuance of the anthracite industry even more difficult than it has been made as a result of the frequent strikes of the miners.

At the same time it is not desirable that new regulations be imposed on the railroads. Such a step could very easily break down once more the credit they have so laboriously built up since the government's experiment in operating them during the war.

P. & A. Photos

**William H. Woodin**

Elected president of the American Locomotive Co. last week. He also will retain his position as president of the American Car & Foundry Co., with which he has been identified since its inception, in 1899. He was Fuel Administrator of New York State during the latter part of 1922, following the general coal strike.

The anthracite labor situation is complicated by the miners' license law, which makes it unlawful for any miner, no matter what his experience or competence, to work as such in Pennsylvania unless he has been employed in that state for at least two years as an anthracite miner's helper, and has been granted a certificate by a state board of examiners composed of practical miners. Many important business interests in the State of Pennsylvania believe this law is unreasonable and discriminatory. It has had much to do with the serious trouble with which the anthracite industry has suffered since its passage in 1897.

Your committee on internal trade and improvements believes there is no more reason for congressional action looking to the regulation of the production and sale of anthracite coal than for similar legislation as to copper, wool, oil, wheat, sugar, or any other staple commodity.

# Mines Co-operate to Fight Oil Competition

A unique plan has been worked out by coal mining companies of western Washington to combat the competition of fuel oil, particularly in heating dwellings. The Pacific Coast Coal Co., Seattle; Bellingham Coal Co., Bellingham, and Wilkeson Coal & Coke Co., Wilkeson, have formed a corporation known as the Automatic Coal Burner Co., of Seattle, and through this agency are marketing a new type of automatic coal stoker, which has been installed by apartment-house and dwelling owners to replace fuel-oil systems, and greater efficiency is claimed for the new device.

The new automatic coal stoker consists of a hopper, which is filled with sufficient fine coal for a day's requirements, and a motor with a screw drive which feeds the fuel into the firebox under thermostatic control. The owner sets the thermostat and the stoker automatically keeps the heat within two degrees of the temperature indicated. Besides utilizing a cheap grade of fuel, less coal is used and there is no loss in handling or storage. The most outstanding advantage pointed out by the users of the device is elimination of the explosion hazard attendant upon using automatically controlled fuel-oil burners.

# Vandalism Renewed in W. Va. Strike Zone; Union Builds Barracks

Violence broke out in the northern West Virginia coal fields again last week, when vandals tried to burn down the wagon-mine tipple of W. F. Shafer early Dec. 3 at Brummage mine, near the city limits of Fairmont. The tipple, which is small, was saved from ruin by the city fire department.

Three alleged union miners tried, Dec. 1, in the Harrison County Criminal Court at Clarksburg for burning down the tipple of the Consolidation Coal Co. at mine No. 55, at Meadowbrook, Harrison County, on Aug. 29, were acquitted.

The Consolidation Coal Co. has 200 or more miners at work in the Monongah mine and substantial progress is being made at the three mines of the company at Wyatt.

Coal production at non-union mines in the 12½ counties of northern West Virginia totaled 7,185 cars in the first four days of last week compared to 5,887 cars for the corresponding period of the previous week, which was low because of the observance of Thanksgiving Day. Union mines in the first four days of last week loaded 1,173 cars of coal compared to 886 cars in the corresponding period of the previous week.

On an average 220 non-union mines were at work in the region during the first four days of last week. Fourteen union mines worked daily on the average in the region in the same period. The largest number to work was 16, on Nov. 30 and Dec. 1. Since then the two union mines on the Monongah Division, B. & O., have closed down.

Officials of the United Mine Workers said early last week that they will be obliged to care for 1,400 families of striking union miners by Feb. 1, due to evictions which various coal companies will exercise. The work of erecting additional barracks was well under way last week.

It is reported that approximately $100,000 a month is being spent in the Fairmont field for relief at present.

# 65 per Cent of Bay State's Hard Coal Needs In

Stocks of domestic anthracite in dealers' yards in the State of Massachusetts on Nov. 1, 1925, according to the Special Commission on the Necessaries of Life, totaled 336,908 net tons. As stocks on hand April 1 were 725,558 tons and receipts from April 1 to Oct. 31 inclusive were 2,952,744 tons a total of 3,678,332 tons has been available for distribution, or approximately 72 per cent of the state's coal-year requirements based on deliveries between April 1, 1924, and March 31, 1925. Deliveries to consumers for the seven months April to October inclusive were 3,341,424 net tons, or 65 per cent of the year's requirements. Stocks in the metropolitan Boston district on Nov. 1 were 142,097 net tons; deliveries, April to October inclusive, 1,335,990 tons; deliveries, coal year, 1924-25, 2,053,630 tons.

# Crisis in Hard-Coal Strike at Hand, Washington Sees Lasting Settlement Or Makeshift Peace in Public Hands

**By Paul Wooton**

Washington Correspondent of *Coal Age*

Whether this anthracite strike settles anything or whether it is to be just one more patchwork compromise is largely in the hands of the public now. The critical period of the struggle seems to have arrived. If the public sustains the anthracite operators in their refusal to have any of Governor Pinchot's tinkering, the suffering they have undergone thus far will not have been in vain, many think.

The hard-coal producers have done all they can do. They are holding fast for the principle of arbitration. They have nailed their colors to the mast, but public support is necessary or they will be torn down and a settlement that does not settle will be forced. If the public allows itself to be deceived by Mr. Lewis' claim that the miners are for peace while the operators have declared for a continuance of war, the odds may be swung against the operators and there will be another evasion of fundamental issues that will not down.

Two things are demanded of the public at this time if it wishes to avoid frequent recurrence of the experiences of the past three months. One of these things is to continue to accept cheerfully the inconvenience of substitutes. All that is necessary is for anthracite consumers in other states to emulate the example of the New England Yankees, who have pointed the way to independence from biennial coal strikes. They believe the sacrifice of convenience is not too much to pay for the cure of an ill that has become a running sore on the body politic.

### Stack Cards Against Operators

The other thing which the public may do to protect its own best interest in this situation, competent observers assert, is to take care to distinguish between camouflage and reality. Governor Pinchot and Mr. Lewis have camouflaged compromise and are parading it as arbitration. What they really are offering is a stacked deck of cards—stacked against the public and against the operators in favor of the mine workers. The results of the brand of alleged arbitration which they are sponsoring can favor only one party to the controversy. The need of economy and increased efficiency is stressed, but the sole beneficiaries are to be the miners. If the impartial tribunal discovers that profits are needlessly large or if it finds a way of cutting costs, the entire surplus, the whole saving, is to go to wages. That the operators rejected such a clumsy semblance of arbitration causes no surprise in Washington.

Real arbitration, it is pointed out, does not prejudge the verdict. By agreement arbitration may limit the subject to be considered but would not direct arbitrators to find for one side. The great need of the hour, public-spirited observers say, is that the public recognize the spurious character of the Pinchot settlement.

Some newspapers are condemning the operators for prolonging the strike. It is notable, however, that such a reaction comes largely from newspapers that frequently express half-baked and superficial editorial opinions or from newspapers that are notoriously demagogic. The well-informed and profound thinkers among the editorial writers will be found supporting the position of the operators.

The real need of the situation would appear to be, however, a mandate from the consumers of anthracite that no settlement be accepted until there shall have been written into the terms of the contract a provision for keeping the mines in operation during negotiations and for the submission to arbitration of all points on which agreement cannot be reached.

## Glace Bay Living Conditions Worst Ever, Says Doctor

At the session of the Nova Scotia Coal Commission at Sydney, C. B., on Nov. 18 James B. McLachlan, former secretary-treasurer of district No. 26, United Mine Workers, and a prominent Communist, asserted that the object of the British Empire Steel Corporation in fixing wages was to make operations pay dividends on idle assets.

When the examination of McLachlan was continued on the 19th, he stated at some length his views on labor conditions and education. He said he believed that there would be no end to the unrest until the men had enough to live on and the fear of unemployment was removed. The Communist party, he said, had changed from a territorial body to a factory organization. Several miners testified as to unfavorable working conditions at Colliery No. 22, where men from Birch Grove and Port Morien were employed. Not enough working places were provided.

Dr. A. S. Kendall, county health officer, testifying Nov. 20, stated that the water supply was inadequate and the sewerage system defective. Many of the houses were unsanitary and some that had been recently built ought to be torn down. The provincial and municipal governments, he said, should join with the coal company to bring about more modern conditions.

Dr. McAvoy stated that he believed that living conditions on the average in Glace Bay were the worst of any place he had seen. The issue of the last strike was clearly defined as to whether the wages should be cut. Dr. D. J. Hartigan, of New Waterford, testified that sanitary conditions were not good, the open drains being a menace to public health.

---

## *Test Coming on Fines For Illegal Strikes*

A strike of miners employed at No. 2 shaft of the Buffalo & Susquehanna Coal & Coke Co., at DuBois, Pa., promises to develop a case that will test the fining clauses of wage agreements. This company had imposed a fine of $1 per day on miners for violating the agreement in striking and thus shutting down the mine. The fines amounted to approximately $29 each on 400 miners.

The United Mine Workers had two men bring suit against the company for a refund of the money. The action was brought before a justice of the peace in Sandy township. The company did not appear and judgment was entered by default. The case will be appealed to the Clearfield County Court. The provision for the fine was first put into the wage agreement in 1917 by the U. S. Fuel Administration as a disciplinary measure to prevent outlaw strikes and this is the first time the United Mine Workers has resorted to legal action to resist the collection of such fines.

---

## Mining Congress Studies Output and Distribution

Secretary of Labor James J. Davis, Secretary of Commerce Herbert Hoover, Federal Trade Commissioner William E. Humphreys, Representative Joe J. Manlove of Missouri, James Murdock, former Minister of Labor of Canada, and leading mining men from all parts of the United States were scheduled to discuss important questions affecting the production and distribution of mine products at the twenty-eighth annual convention of the American Mining Congress at the New Willard Hotel, Washington, Dec. 9, 10 and 11. The convention was to consider a national labor policy, mine taxation, joint selling agencies in the distribution of mine products and other important mining problems.

Among those who were to outline the requirements of the mining industry in the various mining districts of the country were M. L. Gould, of Indianapolis, Ind., president of the National Coal Association; S. D. Warriner, of the Lehigh Coal & Navigation Co., Philadelphia, and Harry N. Taylor, president of the United States Distributing Corporation, New York.

---

## Russian Coal Output Lags Below 1913 Level

During the first nine months of 1925 the total production of coal in Russia was 16,107,000 tons. Of this quantity the Donetz district produced 12,328,000 tons; the Ural district, 1,300,000 tons; Siberia, 1,070,000 tons; the Far East, 700,000 tons; the Moscow district, 556,000 tons, and other districts, 153,000 tons. The output was 56.8 per cent of that of 1913.

## Of 86,000 Killed Annually Less Than 2,400 Perish In Coal-Mine Accidents

Eight times as many men are killed by automobiles as by all causes in coal mines, according to J. V. W. Reynders, president, American Institute of Mining & Metallurgical Engineers, at the joint safety conference in New York City which was fostered by the American Society of Safety Engineers—Engineering Section, National Safety Council and the four "parent" societies, the American Institute of Mining & Metallurgical Engineers, the American Society of Mechanical Engineers, the American Society of Civil Engineers and the American Institute of Electrical Engineers.

Mr. Reynders said that the dangers of coal mining had been greatly overestimated by the public. There were 18,000 fatalities yearly from automobiles and in 1924 only 2,381 fatalities in coal mines. The public, impressed by disasters that gave opportunity for sensational headlines, had become obsessed with the idea that the hazards of the coal industry were much greater than they actually are. So needful had it been to make sensational appeals to Congress in order to obtain funds that the training cars of the bureau had been named mine-rescue cars, though that was only a part of the work that such cars performed.

The death rate in the coal-mining industry figures out so that a 1,000-ton mine, which is quite a sizable operation, averages only about one fatality per year. Mr. Reynders, who is presiding officer of the Advisory Board to the Bureau of Mines, did not, however, regard this as any reason for curtailing the activity of the bureau in the work of safety. Ten cents per ton would not, he said, be an expenditure in the minds of most mining men too large for the promotion of safety in mines. That would be an appropriation of $60,000,000. Instead the bureau receives barely ½c. for every ton mined. He considered the investment a most excellent one.

### Annual Loss, $2,390,000,000

Another interesting paper at that meeting was read by W. C. Dickerman, vice-president of the American Car & Foundry Co., New York City. Mr. Dickerman declared that there were 86,000 deaths from accidents annually and more than 2,000,000 persons were injured. He added that the loss due to accidents was $2,390,000,000 annually. He said that his company had in 14 years spent about $1,000,000 in safety and had saved thereby $2,700,000. He mentioned a brick company whose accident costs were 18.3c. per thousand which had cut the cost to 5c. per thousand, and a construction company that had reduced its accidents 76 per cent. He recalled also the record of the United States Steel Corporation. It had spent $9,700,000 in safety and saved $14,500,000 thereby. He declared that safety work decreased turnover, bettered and increased product and improved morale. Harry Schulze, who spoke later, said that the United States Steel Corporation had cut fatalities 61 per cent and accidents 79 per cent. However, the company regarded the economies of its safety work as the least of its returns. The satisfaction of reducing hazards was greater than any attained by reason of the economies effected.

**E. B. Jermyn**

After a close and bitter contest, Mr. Jermyn was declared elected Mayor of Scranton, Pa., in a court opinion delivered Nov. 25 by Judge H. A. Fuller, who had been named by the state Supreme Court to act as umpire. Mr. Jermyn, who ran on the Republican ticket, won over his Democratic opponent, M. J. McHugh, at present Chief of Police, by the narrow margin of 109 votes. The Mayor-elect served as the city's chief executive from 1914 to 1918. He formerly owned the Langcliffe colliery, near Avoca, Pa., which he operated for a little more than a year.

Walter Rautenstrauch, professor, Columbia University, New York City, declared that ten fatalities occurred in the United States for every hour of the day and night and that, estimating the wages of industrial workers at $40,000,000, the loss from accidents was 5 per cent of that sum.

E. A. Holbrook, dean of the School of Mines, Pennsylvania State College, State College, Pa., spoke in favor of the recognition by colleges of the importance of safety and stressed the greater activity shown by mining colleges in this needful portion of the curriculum.

S. D. Keller, professor of industrial management, of the same college, discussed the same subject and declared that only 5 per cent of all accidents were industrial, 25 per cent occurred in the home and 50 per cent occurred in public places, two-thirds of these last being traffic accidents.

Harold Seagrove gave a demonstration of the use of a mixture of 5 per cent carbon dioxide and 95 per cent oxygen in resuscitation, showing that with normal breathing, breathing induced by the prone-pressure method and breathing intensified by the aforementioned mixture the relative volumes of air expired were 0.41, 1.60 and 1.74 respectively.

The three sessions were presided over by Kingsley Martin, chairman, Metropolitan Section, A.S.M.E.; Robert Ridgeway, president, A.S.C.E., and Michael Pupin, president, A.I.E.E.

## Alberta Coal Control Urged by Stutchbury At Canadian Institute

Remedies for some of the ills of the western Canada coal-producing regions were proposed by Howard Stutchbury, trade commissioner for the province of Alberta, at the seventh annual western meeting of the Canadian Institute of Mining and Metallurgy in Winnipeg, which was held Nov. 3, 4 and 5. The coal session of the convention occupied one day and was presided over by J. A. Richards, inspector of mines. Several addresses were made.

Mr. Stutchbury, in his paper, held out for a stronger anti-dumping law against foreign coals, urged lower freight rates on Alberta coal for the East and suggested a method of reducing the number of "gopher-hole" mines by commission control of all crown lands.

The problem of the "gopher hole" mine is a very serious one to the Alberta operators, being caused in the speaker's estimation by the present regulations affecting coal mining in that province. In 1924 there were 399 producing mines in Alberta, 322 of which produced only 5.66 per cent of the coal mined. Alberta is dotted with abandoned mines of this variety, said Mr. Stutchbury, and "in my belief, it would be in the interests of economy and conservation if many of these mines were consolidated."

A certain section of the coal operators felt that the suggestions were too drastic and would prevent proper prospecting and exploration work, and would entail a great hardship on certain small operators. Mr. Stutchbury refused to enter into any discussion on his paper, stating that the questions involved were too momentous to the coal trade generally to be lightly discussed and that the time was too short to even touch on the subjects.

George R. Pratt, Alberta government fuel engineer, of Winnipeg, read a paper on "The Winnipeg Market for Alberta Coal." In an interesting paper on "The Steam Coal Situation in Manitoba," George B. Saunders, manager of the Consumers Coal Co., declared that the Western mines producing steam coal will find a better market this year in Winnipeg than formerly because lower wage schedules have been signed by the mine workers and because the duty on slack coal coming in from the United States has been raised to 50c. per ton.

## Southern Ry. Denied Permit for Kentucky Extension

The Interstate Commerce Commission has denied an application of the Southern Ry. for privilege to build 20 miles of road from one of its Virginia points into the Harlan County coal fields of southeastern Kentucky. It was held that the Louisville & Nashville R.R. is adequately serving the territory and that it has surveys and plans for extensions and lines connecting with the Carolina, Clinchfield & Ohio R.R., which are now pending before the Commission. Commissioner McChord dissented in the opinion.

# Senator Oddie Reintroduces Coal Bill In Modified Form

Tasker L. Oddie, chairman of the Mines and Mining Committee of the Senate, has reintroduced his coal bill, with important changes.

The provisions for withholding cars from those who fail to report basic facts has been eliminated. The legislation has been divorced from the Department of Mines bill. The Bureau of Coal Economics which it proposes now is placed in the Department of Commerce. The bill also proposes the creation of an "under secretary of Commerce" who would be in immediate charge of a major subdivision of the department, under which all its mining activities would be concentrated.

The bill calls for the creation of advisory committees, one for the bituminous and one for the anthracite industry, who are to confer with the Secretary of Commerce to discuss plans for "storage of coal by the consumer; supply and distribution of coal in times of emergency; equitable adjustment of royalty rates; taxation policies; prevention of waste; improvements in underground management; removal of restrictions on output; the free introduction of machinery in the coal mines under safeguards that will protect the rights of employees; relief from irregular operation and overdevelopment; integration of the industry into larger productive units; improvements in the preparation of coal for market; the training of mining engineers and foremen; the prevention of accidents and compensation for the same; the improvement of housing, sanitation and living conditions in mining communities; improvements in the transportation of coal, including methods of mine rating and car distribution; elimination of needless cross hauls and long hauls, and bulk handling at yards, terminals and ports; improvement in marketing, including standardization of contracts, inspection and grading, wholesale methods, retail costs and methods, and co-operative marketing and buying; promotion of the export coal trade; standardization and simplification of accounts and reports; development of trade statistics; constructive activities of coal trade associations; economy in the use of fuel and power through better combustion, electrification and improvements in gas and coke manufacture; increase in available supplies of household fuel; improvement in labor relations, including reduction of absenteeism and labor turnover, personal management, improved machinery for the adjustment of grievances and the negotiations of wage agreements; and such other possible improvements in the methods and practices of the mining, transportation, distribution and use of coal as will foster the growth and prosperity of the industry and the welfare of the mine workers, and as will insure the public a steady supply of fuel at minimum prices."

The bill also provides for the inspection and grading of coal which, however, is to be on a voluntary basis. It provides for the adoption of an export certificate, if and when the producer desires that such a certificate be extended. It directs the Secretary of Commerce to formulate, with the advisory committees, a plan for distribution of coal during emergencies.

## *Real Earnings of Contract Miners In Anthracite Fields*

Are contract miners in the anthracite fields underpaid?

John L. Lewis, international president of the United Mine Workers, insists that they are. He has repeatedly drawn upon the reports of the Coal Commission, with their misleading figures basing earnings upon the number of starts made, to support his assertion. In a statement published in the Sept. 15 issue of the *United Mine Workers' Journal*, Mr. Lewis declared that the average was $1,700 per year, from which "there must be deducted over $200" for supplies.

Check of actual payrolls, however, tells a far different story.

For example, in 1924, the West End Coal Co. worked 292 days and employed 289 miners. Although full-time work was offered to all, only 174 men, or 60 per cent, worked regularly enough to appear on each of the 24 semi-monthly payrolls. Those that took full advantage of their opportunities earned over $4,000 *net* and averaged less than 6¾ hours per day. The average earnings by $100 groups for the 174 were as follows:

| Miners | Average Annual Earnings | Miners | Average Annual Earnings |
|---|---|---|---|
| 12 | $4,161 | 12 | 2,561 |
| 1 | 3,445 | 11 | 2,448 |
| 5 | 3,358 | 8 | 2,334 |
| 5 | 3,241 | 18 | 2,255 |
| 4 | 3,160 | 12 | 2,165 |
| 6 | 3,034 | 9 | 2,037 |
| 10 | 2,969 | 12 | 1,957 |
| 9 | 2,853 | 11 | 1,846 |
| 13 | 2,754 | 1 | 1,733 |
| 13 | 2,674 | 3 | 1,680 |

The average per man for the entire group was $2,613. Over 50 per cent of the group earned more than $2,500 per annum. Less than 16 per cent of the group received under $2,000. Only 24 of the 174 worked every day the mine was in operation. The three men in the lowest rated group ($1,680 per annum) worked only 249 days.

Unskilled labor in this colliery was paid 58c. per hour, as compared with rates of 25 to 45c. per hour in other industries.

## Attack Non-Union Miners at Pittsburgh Coal Co. Mine

Two negro miners were beaten severely, two deputy sheriffs were slightly injured and considerable excitement resulted at Library, Pa., Sunday, Dec. 6, when a mob believed to include members of the United Mine Workers and their wives attacked employees of the Pittsburgh Coal Co. The attack followed a mass meeting held by the union miners at Library, where the coal company is operating Montour No. 10 mine on the 1917 scale.

The tipple was stoned by the mob and the two deputies were injured by missiles. The negroes were attacked as they alighted from interurban street cars. One man was imprisoned in an automobile and carted from one point to another, being beaten at each stop.

The Pittsburgh Coal Co. set a new production record for the five mines working in western Pennsylvania under the 1917 scale in the week ended Dec. 5, when 19,755 tons of coal was produced. The amount loaded by each mine was Banning No. 2, Youghiogheny River, 6,378 tons; Banning No. 1, 4,503 tons; Midland mine, near Canonsburg, 5,300 tons; Montour No. 10, Library, 3,059 tons, and Mansfield mine, at Carnegie, 515 tons. The number of men at work by the end of the week was 1,040, a new maximum.

## To Discuss Economic Branch Of Mine Bureau

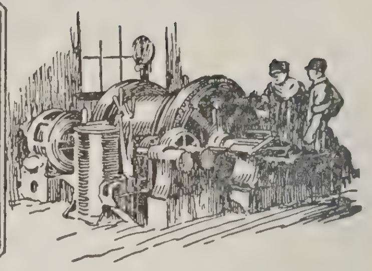
An important meeting of the Bureau of Mines advisory committee will be held Dec. 12 in Washington. Final reports of the sub-committees will be submitted at that time and the organization of the new economic branch discussed. The broad outline of organization has been approved but much remains to be done in the way of subdivision and in the selection of personnel to head up the commodity sections. C. P. White, in addition to his duties as assistant director, will continue to direct the coal work, which is expected to absorb one-half of the appropriations that will be available for use in the economic branch.

It is expected that most of the commodity places can be filled from the present staff of the Bureau, but one requirement will be a first-hand knowledge of the industrial side of mineral commodities.

## Brings Contempt Verdict For Stream Pollution

Seven coal companies and four individual operators were adjudged in contempt of court following a hearing in Fayette County (Pa.) Court Dec. 3 in the Indian Creek water case. The case resulted from an order in which the coal companies were directed to abate the pollution of water in Indian Creek from mine workings. The Rogers Coal Co., Warwick Coal Co., Mill Run Coal Co., Charles Rose, John W. Barger, trading as Rice & Watkins Coal Co., Laurel Run Coal Co., Indian Ridge Coal Co., Ralph Ritenour, Simon Snyder and the Wingrove Coal Co. were the parties haled to court.

# Practical Pointers For Electrical And Mechanical Men



## Portable Cord Serving as Cable For Underground Power

Coal cutters and loading machines used in Mine A of the Pike County Coal Corporation, Petersburg, Ind., are operated by 220-volt induction motors. The use of this type of motor requires that the voltage be held close to normal. This means that power must be taken into the mine at a voltage of 2,300 or more, and that the step-down transformers should be kept close to the motors.

It would be an expensive proposition to distribute the alternating-current energy from a centrally-located entrance, especially to motors which have no permanently-fixed location. At Mine A the 2,300-volt energy is distributed on pole lines along the surface and taken down through boreholes. The cover over the coal is fairly uniform in thickness, averaging about 100 ft. To this depth it is not expensive to drill a 6-in. borehole which is the size used for the 2,300-volt cables.

A feature of the borehole installations is the inexpensive electrical construction. This is indicated by the accompanying photograph. A No. 10 three-conductor rubber-sheathed cord is used. Each conductor is made up of 81 wires covered by a $\frac{1}{16}$-in. wall of rubber. The outer sheath consists of $\frac{3}{32}$ in. of rubber and the overall diameter of the cord is approximately $\frac{5}{8}$ in. The weight is only about 35 lb. per 100 ft.

The cord is carried down through the borehole in a $\frac{3}{4}$-in. iron conduit, which is supported at the top of the hole by a clamp resting on the end of the 6-in. borehole casing. The cord is so light in weight that it is supported by a firm wrapping of tape at the top of the conduit. A means of opening the circuit, and protection in case of trouble, is afforded by fused cutouts on the pole.

At the bottom of the borehole the $\frac{3}{4}$-in. conduit and No. 10 cord both end at a junction box from which a standard 2,300-volt rubber cable extends to the transformers. The maximum distance that the transformers are allowed to be located from the borehole is approximately 1,300 ft. When the mine development gets beyond that limit, a new borehole is drilled. The transformers, three in number and each of 37.5-kva. capacity are mounted on a mine-car.

The connected load on each bank of transformers consists of a 125-hp. motor driving the hoist of a loading machine, a 15-hp. motor driving the dumping platform, a 5-hp. motor driving the car spotter, and a 50-hp. motor driving the mining machine. The fact that the mining machine is not used while the loading machine is in operation, and that the load is intermittent on the hoist, makes possible the use of the small conductor through the borehole.

**A Small Cable for a Big Job**

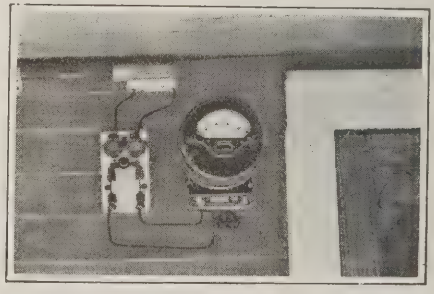
This No. 10, three-conductor, rubber-sheathed cord, approximately $\frac{5}{8}$ in. in diameter, carries 2,300-volt energy through the borehole to a connected load of 195 hp., but shows no sign of overload.

### 300 Kw. Cut from Load by Metering Houses

When electric light lines to company-owned houses in coal towns are not metered it is the common practice to charge the house occupant 25c. per lamp per month and to maintain 24-hr. service. Most coal companies operating with this arrangement lose money on their house lighting. The plan also encourages the theft of headlight lamps and of other high-wattage lamps from the mines and company buildings. In certain instances there are other disadvantages of a flat rate. Metering usually is preferable. A specific case is that at the Stone division of the Fordson Coal Co. in Kentucky.

At Stone a reduction of 300 kw. in the power plant load resulted from the installation of meters in all houses and company buildings. This reduction was desirable because of the overloaded condition of the power plant equipment.

The accompanying photograph of a meter on the front of a miner's home at Hardy, Ky., is typical of all of those on the Fordson houses. Approximately 1,200 meters were installed at mines of the Stone division. The rate now charged is 8c. for the first 25 kw.-hr., and 5c. for all energy more than this amount. It is the intention to lower the rate to 5c. and 3c. as soon as certain improvements have been completed.



**Meter on House at Hardy, Ky.**

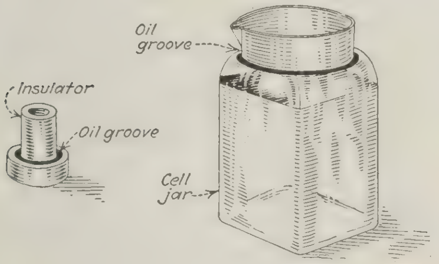
The meter is located on the porch close to the ceiling. This installation is typical of all of those on the Fordson houses. About 1,200 meters were installed at the Stone division.

in the power plant, for taking care of additional load.

The care and reading of the 1,200 meters takes about one half of one man's time. The cost of power used in company buildings such as commissaries, recreation halls, and club houses is charged each month against the respective departments. This practice encourages the turning out of unnecessary lights. The application of meters to double houses necessitated splitting of the wiring into two circuits. In most cases this practically meant that one side of the house had to be rewired.

## Oil Ring Prevents Current Leakage from Cells

Anyone who has been in charge of mine electrical equipment is familiar with the leakage which invariably takes place from cells used for signaling. These cells usually are of either Leclanche or bichromate type. Mining conditions, especially below ground, are often damp and it is difficult to prevent leakage due to the moisture-laden atmosphere causing a conducting surface over the cell jars and about the boxes in which they are placed.



**Oil Grooves Stop Leaks**

A ring of oil formed by a recess in the insulator (left) prevents surface leakage to ground. Cell jars (right) can be made so that an oil groove around the neck stops current from passing down the side of the jar.

### Acid Causes Leakage

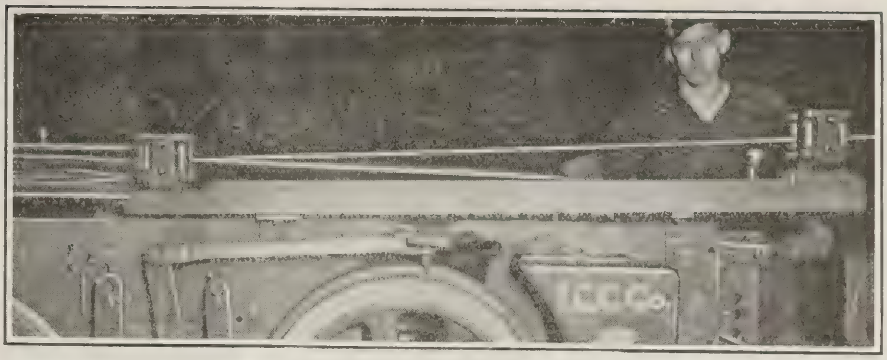
Leakage is to some extent counteracted by a coating of shellac or paraffin placed around the necks of the cell jars during the process of manufacture. This, however, is not sufficient to prevent the acid creeping by capillary attraction down the outside of the cells to the box and setting up leakage which prematurely discharges the whole battery, causing increased maintenance costs and interfering with the efficient operation of the cells. This trouble is often aggravated by operators allowing water or acid to spill when the cells are being recharged.

Much of this leakage can be overcome by dividing the cells into small groups placing each on a board supported on insulators. A better plan is to employ insulators provided with a groove for carrying a small quantity of heavy insulating oil or grease as shown at the left in the accompanying drawing. An alternative is to have the cell jars made with an oil groove just below the lip as shown at the right in the sketch. The advantage of this method is that each cell is provided with its own insulation ring, which effectively prevents creeping of acid, and insures protection against leakage.

L. Fokes.

England.

## Grounds Are Reduced by Insulated Guides



**These Cable Guides Are Safe**

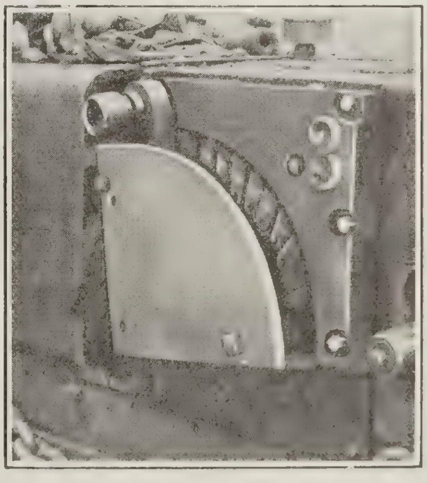
When they are not insulated the combination of a bad cable and a worn roller results in a short circuit close to the motorman's eyes. With the arrangement shown here there is little chance of the cable touching any part of the locomotive and becoming grounded. The guide unit can be changed by removing two bolts.

Several years ago the Island Creek Coal Co. found that it is worth while to insulate cable reels from the frame of the locomotives. A comparatively recent practice of the same order is that of insulating the cable guides. This not only reduces delays and repair costs, but also is a safety feature of importance.

In time, reel cable becomes frayed and likewise the wooden rollers of the guides wear or break, thus exposing the metal parts. When the body of the guide is not insulated from the locomotive frame, the combination of a bad cable and a worn roller will result in a ground which forms a short circuit from the trolley to the rail through the cable. The common result is a severed cable and an interruption of power to that section or to the whole mine by the opening of a circuit breaker. Far more serious results are injury to the motorman by the arc, and a wreck caused by his falling or jumping off the locomotive.

The method used at the Island Creek mines to insulate the cable guide from the locomotive is shown in the accompanying illustration. The two guides are mounted at the ends of a piece of 3x4-in. oak plank, the use of which brings one guide beyond the end of the top of the locomotive. This, and the fact that the wood is continuous between the two guides minimizes the chance of the cable touching any of the grounded parts of the machine.

All of the gathering locomotives of the Island Creek company are equipped with wood supports. Extra mountings complete with cable guides are kept at each mine. The fact that but two bolts hold the support in place makes the changing of a guide unit an easy matter. The locomotve shown in the picture is one of the oldest in use at the Island Creek mines. It was purchased about 1910 and recently was entirely rebuilt; this included the renewal of all rivets, and it is again practically as good as new.



**Controllers are Guarded**

This electric undercutting machine, No. 3, was "snapped" while being repaired, at No. 8 mine, Stone, Ky. The old type of open controller, with which the machine is equipped, has been guarded by the addition of a sheet of $\frac{3}{8}$-in. fibre, thus minimizing the chance of burns or shock.

# Problems In Underground Management

## "Slab System" Increases Percentage of Lump and Lessens Labor

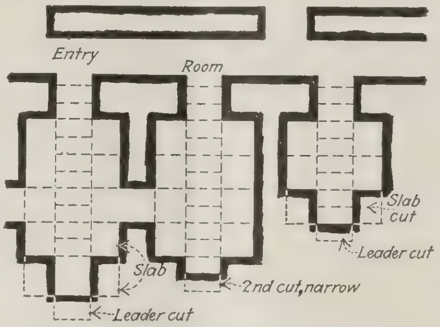
Various methods for increasing the proportion of lump coal produced in mining have been suggested from time to time. Most or all of these schemes have tended either to increase the labor necessarily expended or the cost per ton. Under the plan of working about to be outlined, however, and which I shall term the "slab system," the cost should not be increased and the labor expended should be appreciably lessened while a larger percentage of lump should be obtained.

Under the present usual plan of mine operation a room is necked off the entry or heading. After a certain depth has been attained it is widened out to the full width desired, after which it is driven to the depth limit by a succession of cuts under a straight face.

By the slab system the room would be turned narrow as before, that is, with a width of, say, 12 ft. After this width had been carried in for about 36 ft. a slab cut 12 ft. long is made to the full depth of the cutterbar upon each side of the room thus widening it. On the same shift a face cut is made of the original 12-ft. width. Thereafter two face cuts, or one leader and one finishing cut, are made to each pair of side or slab cuts, the idea being to successively develop 12-ft. slab cuts. To this end, if the cutterbar is more than 6 ft. long the second or finishing face cut may be made of less depth than full bar length.

### Order of Undercutting

After the first two slab cuts (one on either side) have been removed all succeeding slab cuts are left with loose ends. Coal from such cuts requires appreciably less explosive to bring it down than does that for ordinary cuts with tight ends. The order of undercutting would be: On one shift, a leader face cut and two slab cuts would be made; on the next cutting shift, the second or finishing face cut only would be made. This cutting sequence would be followed until the room had attained its full depth limit. The appearance of a mine section operated on this plan may be seen in the accompanying illustration. Naturally, breakthroughs will be driven between rooms at the required intervals and in the ordinary manner.



**Section of Mine Worked by Slabbing.**

Rooms are turned narrow as in the ordinary method, but after a suitable width of entry pillar has been penetrated, slab cuts are made on each side of the room, thus widening it out to both right and left. Thereafter two slab cuts and one face cut alternate with a single face cut. All slab cuts have a loose end and, consequently, do not require as much explosive to bring them down and the proportion of lump is higher than that obtained from faces merely undermined in the ordinary manner.

### System Aids Safety

From the standpoint of safety this system offers many advantages. The method of operation outlined affords an excellent opportunity to support bad roof for the reason that the slab on one side can be shot down, loaded out and the roof timbered even before that on the other side is drilled. The powder consumed per ton of coal produced would be somewhat less than is necessary under the present system, but the proportion of lump would be appreciably increased because of the loose ends of the slab cuts. The drilling required would be exactly the same as under present conditions. The coal brought down, however, would be easier to load because it would naturally fall and roll out toward the track. Impurities could be separated from the coal with greater ease because the pieces would be larger and would not have to be thrown so far to reach the gob. Plenty of coal would always be available for loading because the finishing cut could be made before the slab cuts had been entirely cleaned up.

Opposition from the miners could be anticipated if an attempt were made to introduce this system of working. This is always the case with any improvement. Such opposition would probably center on the narrow work at the face, but I believe that any miner after giving this method a fair trial would find his work so much easier and safer that he would not willingly revert to the system now prevalent.

George E. Harkess.
Shelburn, Ind.

## Booster Sometimes Decreases Ventilating Power

By F. C. Cornet
Brussels, Belgium

It often happens, when developing a mine, where nothing but coal of a certain height is thought to exist, that the entries eventually penetrate a region that is lower than expected, thus choking ventilation and creating opportunities for the use of booster fans. This low-coal area is connected with the shaft or other mine opening by passages through higher coal. The area of high coal already proved may be sufficiently extensive to permit of attaining a large output but the entries in low coal, or some of them, will be driven on in order to ascertain what conditions lie ahead and plans made accordingly.

Headings and air courses in low coal must, of course, be ventilated, and when driving require a water gage higher than places of the same width driving in high coal. If such passages are widened out their resistance to air flow would be lessened. The reverse of this, however, is what occurs in most cases, for as soon as a mine foreman discovers that the coal taken out of an entry ceases to pay the cost of driving he generally reduces the width of the place to just what is necessary to allow the cars and locomotives to pass. The coal may be so low, in places, that the top or bottom, or both, must be cut into, in order to provide sufficient headroom. But slate work is costly and the foreman, consequently, will reduce it to what is strictly necessary. The increase in cross-sectional area resulting from increased height, consequently, will afford but small relief so far as ventilation is concerned.

### TO REDUCE CROSSCUTS

Crosscuts, probably, will be spaced according to law, but certainly they will be reduced throughout a portion of their lengths, to a hole just large enough to allow a man to pass through. Holes of this kind have the undeniable advantage of reducing the cost of the stoppings. Unfortunately, their cross-sectional area is but a fraction of that of the heading, which is already small. Such passages, therefore, interpose an excessive resistance in the path of the air current. The throttling to which this current is thus subjected in the last breakthroughs makes it especially important to arrange for an energetic ventilation when plans are made for driving entries in low coal.

Experience with this kind of work, mostly in Tucker and Randolph counties, West Virginia, has convinced me that one must not base his provisions for ventilating air on what the coal height actually is, nor on what other conditions may appear to be when so-called low coal is encountered, for in all probability things will get worse before they show any sign of improvement. One may be certain in advance that, before the worst is passed, a ventilating water gage higher than that found to be adequate in the contiguous high-coal workings will be necessary. This higher water gage might well be provided for from the beginning.

### WOULD WASTE POWER

Even though the fan ventilating the contiguous high-coal workings may be capable of furnishing the increased water gage necessary this pressure cannot be obtained except by subjecting the entire volume of air handled to this same increased head. In other words, the water gage affecting a comparatively large volume of air would have to be raised unnecessarily for the sake of furnishing a small ventilating current to the low places. I say "unnecessarily," for if the workings in high coal are well ventilated under a given water gage, it is a waste of power and money, to run the fan at a speed greater than that necessary to develop this pressure. The power waste would be proportional to the difference between the volumes required respectively by the high- and low-coal workings. This difference, under most circumstances, would be large.

Suppose the high-coal operation requires 150,000 cu.ft. of air per minute, under a water gage of 1 in. Suppose also, that three pairs of headings in low coal need altogether 3,000 cu.ft. of air per minute, which a water gage of 3 in. is required to insure. Would it be economical to treble the water gage on the whole 153,000 cu.ft. when the result desired could be attained by making the increased pressure affect only 3,000 cu.ft., which could be done with the help of a small booster fan?

### BOOSTER SAVES ENERGY

In the first case, the power necessary to impel the 153,000 cu.ft. of air would be 72 hp. In the second, the corresponding power would be 24 hp., to which must be added 1.4 hp. or that expended on the air handled by the booster. This makes a total of 25.4 hp. The saving in energy resulting from the use of the booster, would thus amount to 65 per cent.

Whether or not the use of a booster would be advisable in this case probably would depend on its purchase price, its cost of installation and on the length of time it would be needed. The latter factor, in most cases, would be unknown.

### WHERE RESISTANCE IS SMALL

However, one other consideration must be taken into account. Where mine workings offer so little resistance to ventilation that such a small water gage as 1 in. is capable of keeping in circulation a volume of more than 150,000 cu.ft. of air per minute, it would be necessary to create an artificial resistance of some kind, somewhere in the path of the air current, before undertaking to drive the fan, which must obviously be large, to a speed capable of generating the desired water gage of 3 in. Otherwise, two new factors will surely come into play that will raise the power consumption well above the 72 hp. mentioned previously. The new factors are an increase in both the volume and the velocity of the air circulating through the high-coal workings. Power consumption varies directly with the volume of air driven, but as the square of the velocity at which this volume travels.

Another contingency that must be considered is that the stoppings and air bridges which, perhaps, were lightly built, may crack and leak under the new conditions that would prevail in the atmosphere of the high-coal workings, due to the trebling of the water gage. Operators, therefore, will do well to think twice before placing artificial obstacles in the path of the air current ventilating their mines. When confronted with conditions similar to those assumed above, most men would probably go the booster way.

---

## Runaway Switch Saves Time and Money

In the Aug. 6 issue of *Coal Age* on page 195 was a sketch of a double-track runaway switch which is in operation at No. 2 Mine of the Union Pacific Coal Co., at Rock Springs, Wyo. This double track is about 500 ft. long, starting from the mine opening to the first entry on a grade of about 10 per cent.

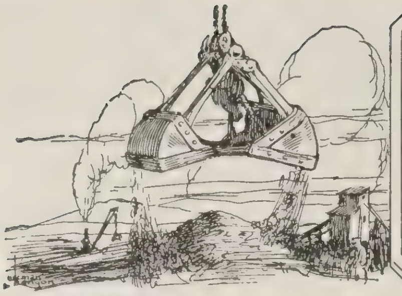
On Oct. 13 it certainly proved itself worthy of mention. A coupling broke near the top, letting eleven cars go back. The runaway cars didn't go far. They were derailed within 100 ft., rubbing against the rib and causing no damage whatever. The other part of the trip was brought back, coupled onto the runaway cars, pulled onto the track again and operation started within 30 min.

### CARS SPILLED LITTLE

The cars are loaded with about a 12-in. top and some were not even broken down. Not more than a ton of coal was thrown off the cars.

Prior to the time this switch was put into operation a runaway of that kind usually caused a delay of from 4 to 16 hr., broken cars and track, and knocked out timber that caused caves. Another feature, no dust was noticed. Does it work? We'll say it does!

CHAS. GREGORY,
Mine Foreman.



# Production And the Market

## Politics Holds Commanding Place in Coal Trade; Mild Weather Handicaps Business

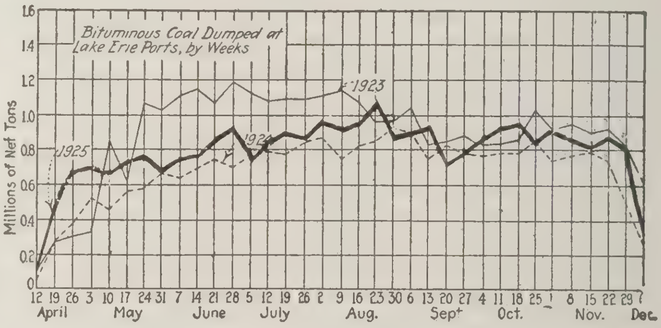
Having taken the stage in the hard-coal controversy, Governor Pinchot of Pennsylvania seems disposed to stick until something tangible has been accomplished—like Mrs. Wiggs, when one plan fails to work he promptly gets to work on another—but whether anything approaching a lasting settlement will result from the Governor's meeting in Harrisburg this week remains to be seen. Some observers profess to see an early end to the strike in the fact that the miners' leaders are at all receptive to plans, but there is nothing surprising about their interest when one remembers —as the operators do—the terms of the Pennsylvania executive's adjustment in 1923.

In most quarters the portions of President Coolidge's message to Congress devoted to coal were considered unusually mild, lacking the specific recommendations for putting the industry in order that many expected. The opening of Congress, however, is fraught with far-reaching possibilities.

Maintenance of bituminous coal production at almost a record rate and the continuance of mild weather have caused symptoms of weakness in the market, though price levels on the whole are being fairly well maintained. Trade in domestic grades is somewhat quieter, steam business pursuing a comparatively even course. The cessation of shipments to the lakes has brought about the usual readjustment, as a result of which there has been a cut in the output of lump and a corresponding falling off in the supply of slack and screenings, with higher prices on the latter.

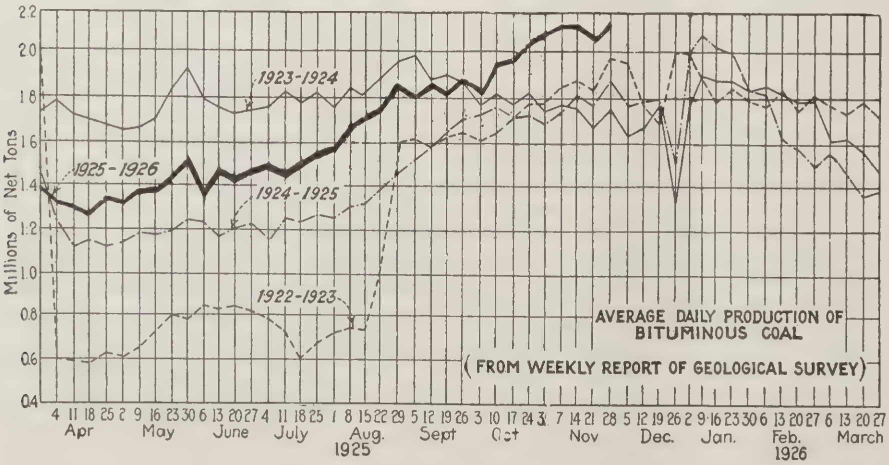
Talk of peace plans in connection with the anthracite situation has made inroads in the market for hard-coal substitutes, consumers showing a disposition to hold back and see what happens. As a result cancellations of orders have been common. There is little doubt, however, that there will be a shortage of hard coal lasting throughout the winter even if Governor Pinchot's efforts should bring about a settlement, and many dealers are of the opinion that heavy buying of coke will continue even when the suspension ends.

Bituminous coal output in the week ended Nov. 28 is estimated by the Bureau of Mines at 11,600,000 net tons, compared with 12,596,000 tons in the previous week. The decline was due to the observance of the Thanksgiving Day holiday. Anthracite production in the week ended Nov. 28 was 36,000 net tons, a decline of 10,000 tons from the week before.



*Coal Age* Index of spot prices of bituminous coal on Dec. 7 stood at 184, the corresponding price being $2.22, compared with 187 and $2.26 on Nov. 30.

Dumpings of coal at Lake Erie ports during the week ended Dec. 6, according to the Ore & Coal Exchange, were: Cargo, 347,329 net tons; steamship fuel, 15,896 tons—a total of 363,225 net tons, compared with 805,424 tons in the preceding week. Hampton Roads dumpings in the week ended Dec. 3 totaled 464,217 net tons, against 483,234 tons in the previous week.



### Estimates of Production

(Net Tons)

**BITUMINOUS**

| | 1924 | 1925 |
|---|---|---|

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Weak Symptoms Appear in Middle West

The Midwestern market during the last week has shown symptoms of weakness, principally because the weather has been mild. Domestic coals have suffered most in the decline in prices. Western Kentucky lump, which had been moving at around $2.50, fell as low as $1.85 for a few cars in distress, with the average around $2@$2.15. High grade 6-in. lump coals from southern Illinois are holding firm at $3.50, principally because the operators are still working on a large number of orders that accumulated at $3.25 before they raised their price last November. Eastern Kentucky and West Virginia high-volatile coals are very weak now. Prices vary all the way from $2.25 for 4-in. block up to $3.75. In short, there is no price, as operators and sales agencies are quoting in accordance with the state of their order books and with the idea of keeping their mines on full running time.

Nobody is interested in hard coal. There is no fuel shortage and the demand for coke continues to be satisfactory. Coke prices remain steady as no demand has developed sufficient to increase current quotations. Nobody appears to take much interest in the hard-coal strike situation.

Steam coals are uniformly stronger. Enough talk has gone around that there is danger of a bituminous strike to stimulate purchases, though no sharp advances in prices can be noted. The industries buying are the larger organizations who consume ten to twelve cars a day and more.

Business is not good in the high-grade field of Williamson and Franklin counties nor is it as good as might be in the Herrin field except on lump, and even some mines have some lump "no bills" while others are a couple of weeks behind, but egg and nut and smaller sizes are slow and hard to move and the circular is not always adhered to. The mines that are working are getting from three to five days a week and railroad tonnage is fairly good. Car shortage shows up here and there and the movement of coal is slow, presaging trouble when severe weather comes. Strip-mine operations show good working time although it has been retarded by quiet weather. Their prices are made to meet competition and competition in Illinois coal is bad when Kentucky coal sells from $1.50 to $2 under Illinois prices with the freight rate 25c. higher on Kentucky than Illinois, and in the face of this, Illinois operators raise their prices.

In the Duquoin field there is not a ready market. Strip mines in this field are doing fairly well while shaft mines are getting four and five days a week. In the Mt. Olive field working time is fairly good. This field enjoys rates to points that beat Kentucky coal out. Steam is slow and railroad tonnage fell off sharply Dec. 1. Prices apparently are maintained in spots. Working time is three to four days. In the Standard field it is a hand to mouth existence with prices about at cost of production and plenty of "no bills" of all sizes except 6-in. lump. Prices vary as much

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Dec. 7 | Nov. 30 | Nov. 23 | Dec. 8 |
| Index | 184 | 187 | 192 | 171 |
| Weighted average price | $2.22 | $2.26 | $2.32 | $2.07 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to he proportions ach of slack, prepared and run-of-mine normally shipped, and, second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1924, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," publshed by the Geological Survey and the War Industries Board.

---

as 50c. a ton on lump coal at different mines. Indications are strong that a proposed merger will go through. Railroad tonnage is light. Working time is three to four days a week with the usual exception. Several mines are idle and all mines carry "no bills." Prices are unchanged.

There is little change in the situation at St. Louis. Coal is moving fairly well for domestic use locally on middle grades and west Kentucky coals, which are beginning to come in heavily; some dealers have given up southern Illinois coal altogether. There is little call for anthracite or smokeless although coke is holding its own. In a general way domestic business is not good and collections are slow. Local wagonload steam continues to show improvement and carload is fairly good, but there is a surplus of coal in the market at all times at all mines on steam. Country steam is quiet but country domestic is fair—buying cheaper coals principally—and there has been a change from Franklin County coals to western Kentucky non-union. No change in prices.

## Kentucky Market Has Possibilities

The Kentucky market is in fair shape, offerings being better on prepared coal, while screenings are tightening up just a trifle. Prices are a little firmer in western Kentucky, where there isn't much shading, but eastern Kentucky prepared sizes have been shaded somewhat on account of larger production, closing down of most of the lake movement and the fact that retailers and other buyers of domestic coal refuse to pay top prices.

Car supply in all sections of the state has improved, loading being faster and cars not being held for long intervals under load at Lake ports awaiting boats.

Domestic consumption is picking up a trifle, although the weather as a whole has been mild over the past ten days. Retailers' stocks are not large, and severe weather would soon bring an active movement of fuel.

Generally speaking, industrial, heating and utility movements are good. Domestic coal is moving into the North and East in better than normal tonnage.

River movement has been somewhat better due to good boating conditions on the Ohio and the fact that some of the West Virginia river shippers are now hustling for river business to replace the lake movement, which is over.

Some eastern Kentucky block coal is priced as low as $2.75 a ton, and some as high as $4, for specialty coal, but the market is around $3@$3.50 for good grade; lump, $2.75 @$3.25; egg, $2.50@$2.75; nut, $2.40@$2.60; mine-run, $1.50@$1.75, and screenings, $1.25@$1.50.

In western Kentucky 6-in. block is $2@$2.25; lump and egg, $1.75@$2; nut, $1.35@$1.50; mine-run, $1.25@$1.50; screenings, pea and slack, 75@85c., and nut and slack, 85c.@95c.

## Warm Weather Brings Lull in Northwest

Warmer weather over the Northwest has been promptly reflected in somewhat of a lull in shipments from Duluth and Superior docks. Car loadings have fallen off during the last ten days, though they are substantially higher than at this time last year. Buying of steam and gas coals by iron and steel plants is especially active. Substantial shipments are going to the Twin Cities to replace Illinois and Indiana coal, which had pre-empted that market before all-rail freight rates were adjusted upward.

Orders from retailers have been light lately, but as stocks are running low in some districts, buying from that quarter is expected to spurt soon. Demand for Pocahontas and other smokeless substitutes for anthracite continues a feature on the market.

Thirty-three cargoes of bituminous coal were unloaded at the docks last week and eleven were reported en route. Coal stocks on the docks at Duluth and Superior have increased to about 4,750,000 tons, of which approximately 2,000,000 tons is owned by railroads.

Quotations are steady and unchanged for both anthracite and bituminous coals, the trade showing no disposition to take advantage of conditions brought about through the miners' strike in the anthracite fields. Inquiry for domestic coke and briquets is gaining and production is being increased correspondingly.

Milwaukee dock managers and retailers report a weather market for fuel. Buying is in small lots and for immediate needs. There is no change in prices, which are steady. The receipts of cargo coal at Milwaukee up to Dec. 3 total 3,609,333 tons. Last year's total on the same date was 3,322,132 tons. During November the receipts by rail were 4,683 tons of anthracite and 45,086 tons of bituminous coal.

The Twin Cities market has been uncertain and irregular, despite the approach of the time when severe weather may set in at any time. The retail domestic consumption is fairly stable, but the steam trade, of which so much had been expected, is still reluctant to take hold. The price schedule is holding fairly steady.

## Supply Catches Demand in Kansas

Continued mild weather has resulted in a light accumulation of lump at Kansas mines. The supply of nut is about equal to the demand, while screenings are a bit short. A little shading is reported, but not as much as in former years under similar conditions. Some operators blame the custom of shading in the mid-season mild-weather slump for the spasmodic market.

In Colorado a sudden rise in temperature has caused a recession in the movement of domestic coal, but few cancellations are coming in. There have been no changes in prices and labor conditions are much improved, with all the mines operating close to capacity.

All sizes of coal are selling in Utah now, but due to weather conditions the demand is not heavy. There is little demand for coal for domestic storage purposes, consumers purchasing in small quantities as they need the fuel. The heating plants are taking coal steadily now, and the demand for steam coal is about normal for the season. Prices are as steady as they ever were; there has been no change since the early fall of last year. Labor conditions are excellent and the car situation is good.

### Readjustment On at Cincinnati

The usual readjustments coincident to the closing of the lakes have been responsible for the feeling-out process that has been on for the last two or three weeks at Cincinnati, regardless of the anthracite strike, weather conditions and all the other market influences.

The tensity of the smokeless situation has eased. While some of the standard Pocahontas houses still held out for $5.50 spot for egg, nut and lump early in the week more of the tonnage was moving between $5 and $5.25 than higher. Mine-run smokeless also was a bit easier, with the market between $2.25@$2.50, the low being obtainable by a little bargaining. Screenings, too, were weaker, more because the big furnaces have come to a place where the market can be squeezed through a letdown in buying orders.

The high-volatile market fared no better. There was a drop of 25c. for West Virginia lump, and egg offerings to the trade went as low as $2.25, where demurrage or "no bills" forced the hand of the seller. A goodly tonnage is still taking as high as $3 or even 25c. better—coal that was bought a couple of weeks ago or stuff that has created a market for itself.

Kentucky block holds up fairly well, but though the price for the month seemed to be around $3.25 a week or so ago, some is being offered around $3 here and there, and a little more warm weather, it is said, would knock it even lower. Because of the Canadian demand for egg the price on this holds up fairly well. Mine-run seems disposed to be the steadiest of the list. A drop in demand for slack has weakened the offerings from both Kentucky and West Virginia another 5c. with $1.10 as the low. High quality slack, such as the Harlans, which had been selling up to $1.50, have eased off to $1.35.

In a retail way there has been little or no change.

River business is at good volume as the tows are favored with a stage that allows an almost regular schedule of discharge.

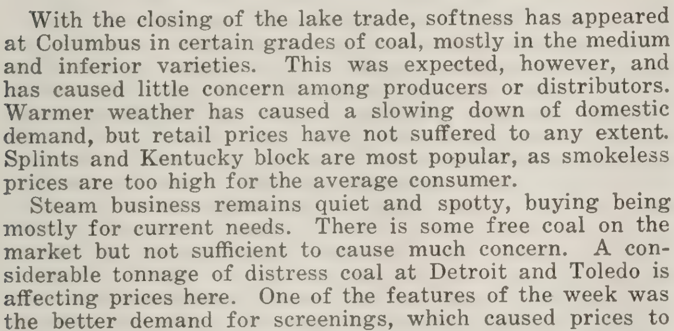
### Lake Closing Brings Softness

With the closing of the lake trade, softness has appeared at Columbus in certain grades of coal, mostly in the medium and inferior varieties. This was expected, however, and has caused little concern among producers or distributors. Warmer weather has caused a slowing down of domestic demand, but retail prices have not suffered to any extent. Splints and Kentucky block are most popular, as smokeless prices are too high for the average consumer.

Steam business remains quiet and spotty, buying being mostly for current needs. There is some free coal on the market but not sufficient to cause much concern. A considerable tonnage of distress coal at Detroit and Toledo is affecting prices here. One of the features of the week was the better demand for screenings, which caused prices to be increased 10c.@15c. per ton. Production is holding up well.

With the cessation of shipments from the mines to the lakes and the prevalence of mild weather, stagnation has overtaken the eastern Ohio market, except on slack and nut-and-slack. "Distress" coal has developed during the week and a slowing up in domestic purchases has caused some cancellations of orders. Pocahontas is now offered at $3.50@$3.75 as compared with $5.50@$6.50 six weeks ago. Other West Virginia and eastern Kentucky domestic coals have suffered a like reaction.

In the steam trade the output of lump has been cut drastically and hence a dearth of slack and screenings has developed, with higher spot prices.



During the week ended Nov. 28 the eastern Ohio No. 8 district produced 297,000 tons or at about the same ratio of operations as in the previous week, but an increase of 57,000 tons over the same week a year ago.

### Pittsburgh Market Still Slipping

The Pittsburgh market has undergone some further weakening both as to demand and as to prices. Regular customers in Pittsburgh and nearby territory are less disposed to act, not that their requirements are diminished but that they have less fear as to supplies in future, with more competition from West Virginia than in the late weeks of the lake movement.

The price of lump has continued to soften, and 3-in. is now quotable at $3@$3.25, with 2-in. and 1¼-in. somewhat easier. There has not been much trading in steam mine-run, but with lower prices for lump the realization is lower and mine-run is affected, being now quotable at $2@$2.10 against $2.10@$2.25 recently. The present market is only a trifle above the level of last summer. Steam slack has now had a second 10c. advance, evidently a reflection of lighter shipments of lump, there being no apparent change in demand. Steam slack is now $1.40@$1.50, gas slack being quotable, as usual, at a 10c. differential above steam.

The market in central Pennsylvania has stiffened noticeably since the anthracite operators rejected Governor Pinchot's peace proposal. Mine-run quotations are as follows: Pool 18, $1.65@$1.75; pool 11, $1.80@$2; pool 10, $2.15@$2.25; pool 9, $2.25@$2.35; pool 71, $2.40@$2.55; pool 1, $2.65@$2.90. Prepared sizes: Lump, $4; egg, $4.50@$4.75; nut, $4. Slack is quoted at $1.50 and prepared coke at $6. Production in central Pennsylvania in November totaled 74,125 cars, compared with 77,974 cars in October. The shorter month, several holidays and five Sundays are responsible for the falling off.

The straight bituminous market at Buffalo is very dull, and there is not much prospect of a revival soon. Recent anthracite developments have hurt the trade some, and the weather is against a brisk market in any sort of fuel. Gas coal is stronger than steam and sometimes brings a little more than regular quotations, which are $1.60@$1.75 for Fairmont lump, $1.40@$1.50 for mine-run and $1.25@$1.40 for slack; $2.25@$2.50 for Youghiogheny gas lump, $2@$2.25 for Pittsburgh and No. 8 steam lump and $1.30@$1.60 for all slack; $1.75@$2 for Allegheny Valley mine-run.

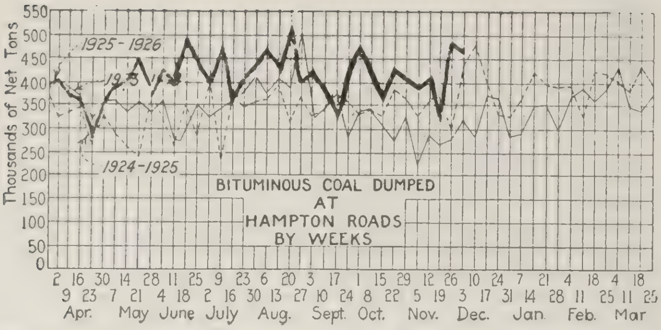
### Demand Is Light in New England

The steam coal market in New England drags along with no developments of any consequence. There is only light demand in every direction, and shippers without seasonal contracts are being pressed to move coal. Not only industries but retail dealers are buying in very sparing amounts; the public is frankly not interested, at least for the present, and the quantity of bituminous actually replacing anthracite has not yet reached any large proportion. Most retail dealers are offering a variety of substitutes from cannel, splint and gas coal to Scotch and Westphalian coke. Connellsville furnace coke had a little vogue here for a time, but high prices turned the demand in other directions and it is probable that during the remainder of the anthracite suspension it will hardly be heard from. Factors here who are trying to merchandise foreign metallurgical coke are having their troubles, and even at $12 on cars the trade is by no means receptive.

At Hampton Roads the volume on cars is heavy and spot sales are only occasional and for relatively small tonnages. Prices range upward from $5.25 for No. 1 Navy standard, but each possible buyer is closely watched. As high as $4.75 per gross ton on board vessel is being asked for New River slack, but almost no sales are reported. This figure compares with a basis close to $4 during the summer.

Shipments all-rail from the smokeless districts to this territory are sloping off, quite contrary to trade expectations. A few operators not in touch with this market have had their fingers burned as a result of sending prepared sizes on consignment. Houses here have been deluged with telegrams asking for offers on coal standing at New England points. With quality grades available from central Pennsylvania at prices less than $5 per net ton at the mine there is no very wide-open market for Pocahontas and New River at much over $4.

Retail dealers are noticing that for the most part con-



sumers are not so critical over substitutes as might have been expected. Apparently there is a disposition to help fight the thing out.

### Mine-Run Has Call at New York

Mine-run continues to feature the market at New York. Buying is heavy as consumers are increasing their reserve stocks as well as using a large tonnage for current consumption.

The failure of screened bituminous to take the place of anthracite, instead of mine-run, has been a surprise to many coal men. Further efforts to spread the use of the latter by house consumers is to be made by the city authorities, who have appropriated $25,000 for the estabishment of coal-burning demonstration stations.

Trade dullness has had its effect upon the shipping of New River and Pocahontas domestic sizes into this market, although several cars have been shipped to Long Island points and further orders have been placed. Quotations range $5@$5.50.

At Philadelphia demand has further decreased following the efforts of Governor Pinchot to bring the anthracite factions together with the idea of resuming mining. The biggest falling off has been in the sized bituminous coals originating in Pennsylvania. The call now is for the better grades, such as pools 1, 9 and 10. There was a slight increase in demand for railway fuel recently, although the prices received are, as usual, a bit under spot quotations. The situation at tidewater is unchanged, with bunkering constituting the chief interest.

Demand at Baltimore, except for prepared sizes, now used as a substitute for hard coal, is not more than seasonal. Prices continue about on the same range as for several weeks past. Industrial demand generally is not overactive, as the majority of business interests, while reporting fair volume, are by no means in the boom stage, or even near it. Exports of coal during November exhibited a gain of 35 per cent over October.

The problem with the Birmingham trade now is not finding buyers but finding coal to meet the market demands. All mines are well booked up on business and there is very little free coal of any quality to be found. Consumers of most every class are represented in the inquiries received and brokers and sales agents are having difficulty in placing orders—in fact much new business is being turned down. Coking coal is short of requirements, the demand for this being especially strong, and the bunker trade is absorbing an unusually heavy tonnage. Railroads, utilities and manufacturing interests are using an abnormal amount of fuel for current requirements and at the same time are endeavoring to creat a reserve supply for the holiday period. All byproduct coke plants are operating at capacity and practically all the beehive ovens in usable condition are now producing coke for commercial use.

Domestic coal is active and the demand for shipments is insistent.

Quotations have shown some increase in the past week, Big Seam ranging $2@$2.25 for mine-run, $2.10@$2.50 for washed, $2.50@$3 for lump; Carbon Hill, $2@$2.25 for mine-run, $2.25@$2.50 for washed, $3.25@$3.50 for lump; Cahaba mine-run, $2.25@$2.50; washed, $2.50@$3; lump, $4.25@$5; Black Creek washed, $2.50@$3; lump, $4.50@$5; Corona mine-run, $2.50; washed, $2.75; lump, $4; Montevallo lump, $5.75@$6 mines.

The coke market is strong with foundry grades quoted $6@$6.50; nut and egg sizes, $4.75@$5.50 per ton ovens. Demand exceeds the supply.

Coal production is at the rate of approximately 420,000 tons per week. Car supply is reasonably adequate now.

### Pinchot's Activity Dulls Hard-Coal Market

With the domestic sizes of anthracite practically out of the New York market and retail dealers' supplies well-nigh depleted, consumers are inclined to use substitutes in larger volume. Peace rumors, coupled with Governor Pinchot's efforts to settle the strike resulted in some cancellations of orders. Buying during the week has been spasmodic. There has been no steadiness and quotations for the available pea and No. 1 buckwheat fluctuated considerably.

Some British coal arrived during the week and it is reported that another cargo of German product is about due in the New York harbor. The British coal is finding a ready market as a substitute.

Quotations for independent pea coal range $16@$16 alongside; No. 1 buckwheat, $8@$8.25; for rice, a small quantity of which was offered, at $8@$8.75, alongside.

Coke's place as a substitute is well established and most retail dealers look for a continuance of heavy buying even after the ending of the hard-coal strike. Retail dealers in various parts of the greater city are quoting coke at $13.50, delivered in bins. An abundance of coke is to be had, but buying is easy. Some grades of crushed beehive coke are quoted at $6@$6.50, ovens. Run of oven product is quoted at around $4.

Governor Pinchot's efforts to end the strike and a continuance of mild weather brought the Philadelphia trade to a standstill. Such buying as is being done by the retail trade is mostly confined to byproduct coke, but buying is so light that there is a plentiful supply. The market for Connellsville and other beehive coke has momentarily disappeared.

Outside of some occasional cars of buckwheat there is very little anthracite moving from company storage yards, and the report is that the largest company has cleaned up all but 50,000 tons of its buckwheat, which is being held in reserve for the local water works and other institutions.

At Baltimore the public is apparently almost uninterested in whether the miners return to work or not as the use of anthracite substitutes grows, and in many cases at less cost than it took to operate heating apparatus with hard coal.

At Buffalo there has been quite an effort to sell bituminous sizes to take the place of the same sizes of anthracite, but the success has not been great. Pea and buckwheat sizes are about all sold out, at $6.85 and $10.35 and that leaves the consumer with nothing to depend on but coke and smokeless, both of which are fairly low in price now. Some retailers are laying down coke at the curb for $12, but the local gas company sticks to $9.50.

### Connellsville Coke Boom Over for Good

Another week has passed without Eastern demand for Connellsville coke reviving and there is no longer any hope that there will be a repetition of the insistent demand, and corresponding prices, that occurred in the latter part of October. Run-of-oven furnace coke then advanced to about $9 as its top, but for only a short time. Some ten days ago it dropped to $4, where it has since been. Iron and steel trade conditions at present would easily warrant a price materially above $3 and perhaps not far from $4.

There is much better demand for broken coke, egg coke, etc., than for run-of-oven, which has not taken well, but some of the prepared stuff is not well prepared. Regular crushed coke with a reputation would sell readily at much above $4.

The blast furnaces using purchased Connellsville coke are no longer seriously concerned as to supplies after present contracts expire Dec. 31. Probably they could contract now for first quarter at $4.50, possibly at $4.25, but apparently they prefer to wait.

Spot foundry coke remains quotable at $5@$6.

# Foreign Market And Export News

## British Coal Trade Reflects Brisk but Irregular Recovery

There is now great loading activity in the Welsh steam coal trade, many steamers having to wait short periods for loading berths at Cardiff and other docks, and there is good prospect of a substantial recovery in shipments for the remainder of the year. The improvement has not been evenly divided, the Monmouthshire market still lagging in demand, although prospects are brightening for that class of coal. Generally speaking the demand has recovered to about the level of twelve months ago but is still far behind the volume of trade of 1923, and until that year's level is reached full activity cannot be restored at the collieries. Prices are now becoming stabilized. In smalls, the tendency is rather firmer for best classes, owing to the increasing bunkering demand in view of the heavier exports.

The strong tone for all sections of the coal market in Newcastle-on-Tyne has been well maintained, for forward and prompt business was easier only because of the difficulty in obtaining tonnage. The general position indicates that the improvement which has set in is more than a passing phase. This is especially the case with coke. The demand has raised values, absorbed heavy stocks and justified the restarting of many ovens in Durham County. Gas coals have the best demand, but all brands of steams move as rapidly as the fuel is turned out. Coking coals have improved with coke.

Production by British coal mines during the week ended Nov. 21, according to a special cable to *Coal Age*, totaled 4,870,000 gross tons, compared with 4,880,000 tons in the preceding week.

## Belgian Outlook Brightens

Weakness still pervades the Belgian coal market, but the steps taken by the government to help the collieries through the present critical period seem destined to improve the position of national products in a certain degree.

The decision of the State Railways not to admit indemnity deliveries from Nov. 10 to Dec. 15 will enable the Belgians to furnish about 50,000 tons, but it is said that this tonnage will be taken only from the Borinage district. The government has decided not to grant any import licenses for free German coals for a month and to suppress all deliveries of indemnity coke dating from Dec. 1, which will improve conditions in the Belgian market and bring pressure to bear on the Germans to reduce official prices.

Industrial coal prices are still hotly disputed. In domestic coals the tendency is more favorable, as cold weather has brought forth more orders than for several weeks.

## French Market Feels Stimulus Of Industrial Pick-Up

In the French coal market the demand for industrial coals is fairly well maintained due to the recovery of industrial activity, and improved financial situation. Winter weather has caused an increased demand for domestic coals. French collieries producing domestic fuels are late with deliveries, British coals are—in some categories—at prohibitive prices, and German coals are arriving in such small quantities that they hardly enter into calculations.

Deliveries of indemnity fuels from the Ruhr in October included 451,400 tons of coal, 231,000 tons of coke and 34,600 tons of lignite briquets. In the first sixteen days of November 104,692 tons of coke was received.

## Trade Regains Momentum At Hampton Roads

Business at Hampton Roads last week was more brisk, with stronger demand and an increase in foreign business. The bunker trade held up well, an increase in general shipping promising well for this end of the business.

Though the tropical storm that swept the coast slowed down shipping for several days, it has picked up without serious mishap. Domestic coal is still high, selling around $12.50 to $13 at retail, but leaving the retailer little margin from his wholesale costs, the price at the mines for Pocahontas grades having gone well above $7. The tone of the market is stronger and the outlook brighter.

# Field and Trade

### ALABAMA

Coal holdings totaling 36,000 acres in Tuscaloosa County, near Lock 17, on the Warrior River, formerly belonging to the Friedman interests, have been sold to the Gulf States Steel Co., it is announced. Although no official statement has been made by the new owners it is understood that the property will be developed in the near future. The Gulf States Steel Co. operates coal mines in Jefferson and Blount counties, with a large steel mill, furnaces and byproduct oven plant located at Gadsden. The general offices of the corporation are in Birmingham, Charles H. Moffett being president.

### COLORADO

The Colorado-Utah Coal Co. recently installed an Ottumwa car loader at Mt. Harris.

### ILLINOIS

At a meeting of the Board of Directors of the Chicago Wholesale Coal Shippers' Association held at the Illinois Athletic Club Dec. 1, the following nominating committee was appointed to present a slate of the officers of the association for the coming year at the annual meeting, which is to be held at the Great Northern Hotel on Jan. 6, 1926: P. H. Holland, James Anderson and T. C. Irwin.

B. Lee Hutchinson, of the West Virginia Coal & Coke Co., went to Chicago Dec. 1 to open a branch office for that corporation in the Windy City.

The stock and property of the defunct Southern Gem Coal Corporation was sold at public auction Nov. 27 in Benton, Franklin County. The purchaser was the Brewerton Coal Co., of Lincoln, and the price paid was stated as $100,000. In buying the properties the purchaser also takes responsibility of all outstanding obligations, including $42,000 in bonds, $91,000 in taxes and payrolls which were unpaid in Sesser, West Frankfort, Pinckneyville and Cutler, aggregating approximately $90,000. The sale was in accordance with orders of Federal Judge George English and is subject to the approval of the court.

William Brinley, who has been the general superintendent for the Middle Fork Mine of the United States Fuel Co., at Benton, for a number of years, has been transferred by his company to the Pittsburgh (Pa.) district and will leave early in December for his new home.

### INDIANA

A terrific boiler explosion Nov. 25 at the Garlett wagon mine, east of Clay City, caused fatal injuries to Robert Garlett, a fireman and son of one of the mine's owners. It is believed that Garlett allowed water in the boiler to get too low, the blast following his turning cold water into the boiler. Top structures of the mine were practically demolished, windows were shattered in nearby residences and parts of the boiler blown more than half a mile from the scene of the explosion.

Willow Creek mine, located near Seelyville, resumed operations Nov. 24, after having been closed down since March 31.

Harold Henderson, Terre Haute, for the past six years general counsel for the United Mine Workers of District 11, has resigned his post in order to devote his attention to his property holdings in Florida, where he also will practice law. His resignation becomes effective Dec. 15. It is understood that John Riddle, at present Henderson's assistant, will be offered the position as head of the union's counsel in the district. The position carries a salary of $7,500 a year.

### IOWA

An agreement whereby the Indian Valley coal mine at Hartford will be operated on a union basis has been reached. Officials of the company told Joe Morris, president of the union, they would make a check-off of half of the initiation fee for admission to the union Dec. 1 and collect the remainder Dec. 15.

### KANSAS

Eighty miners in Clemens Coal Co. mine No. 17, in the southeastern Kansas field, who walked out Nov. 25 in protest against alleged discrimination by the company in hiring new men in preference to old, returned to work Nov. 30 by order of district officials pending an investigation of their charges.

William Hislop, superintendent of the Arma mine-rescue station, assumed the direction of the Kansas central station at Pittsburg, Dec. 1. He was succeeded at Arma by Jesse Rogers, of Dunkirk.

A special election to choose a district auditor to fill the vacancy caused by the registration of Jonah Jenkins was held in District 14, United Mine Workers, Nov. 30. There were thirteen candidates. Returns must be made to the district board before Dec. 10, at which time the results of the election will be announced.

A referendum vote on the question of removal of the headquarters of District 14, United Mine Workers, from Pittsburg to either Frontenac or Arma will be held Dec. 29. The decision was made at a board meeting in Pittsburgh Nov. 24, at which Arma, by written bid, promised $18,000 toward the construction of headquarters, and Frontenac, by the same means, promised free use of a building.

### KENTUCKY

It is reported from eastern Kentucky that the Hatfield Reliance Coal Co. has taken over the mines at Dakota, near Viper, and that car loading started at this plant on Dec. 1, after it had been idle for some time.

Federal Judge Charles I. Dawson issued a permanent injunction at Louisville, on Dec. 1, against the United Mine Workers, restraining members of District 23 (western Kentucky) from interfering with operation of the Lee Land & Mining Co., at Island, McLean County. A temporary injunction was granted several months ago, during strike troubles at the plant.

### MARYLAND

The Stanley Coal Co., which is operating two coal mines adjoining the town of Cullin, has purchased from the Kendall Lumber Co. the town, which is located four miles west of Oakland, for the sum of $60,000. The sale includes 65 dwellings, a large storehouse, wareroom and about 25 acres of ground, but does not include dwellings and lots which are now owned by individuals. The town has a population of about 400 and was founded by R. P. Cullin, in 1892.

### MINNESOTA

The Inland Coal & Dock Co. has let contracts for the building of a 375-ft. addition to its dock at Duluth and the work is now proceeding with a view to its being ready for operation next spring. With the completion of that addition the Inland dock will be one of the largest and most modern at the Head of the Lakes. This is the second addition to it to be undertaken within a year.

### MISSOURI

A verdict disconcerting to operators and dealers interested in the Kansas

City (Mo.) market was returned by a jury in circuit court in Kansas City, Dec. 2, on an appeal by James C. Wilson, a coal dealer, from a police court fine of $100 for delivering coal from the Hume field on an order for Cherokee. Wilson maintained the Hume coal was from the same vein as the Cherokee in an argument which brought a reversal of the police court decision. Cherokee lump is quoted at $5 at the mines on the Kansas City market, Hume coal at $3 to $3.50.

## NEW YORK

The demolition of the New York, Ontario & Western coal trestle at Oswego is planned. It is found that the use for it to handle coal is small and that the traffic needs the space for an extension of the package-freight docks. The Pennsylvania R.R. also is expected to tear down its soft-coal trestle at Sodus, on account of poor business. Anthracite shipments from Lake Ontario ports, mostly from Oswego and some from Fair Haven, for the season of 1925 were 152,474 gross tons, as against 220,510 in 1924. For a long time shipments ran above 600,000 tons annually.

## OHIO

The offices of the Lorain Coal & Dock Co., which have been located in the Huntington National Bank Bldg., Columbus, for about ten years, are to be moved about Dec. 15 to the eighth floor of the New First National Bank Bldg. The company will occupy about two-thirds of the space of the entire eighth floor.

Dumpings at the docks of the Hocking Valley Ry. during the week ended Dec. 2 were 197,213 tons as compared with 188,903 tons in the corresponding week last year. So far this season the docks have handled 8,301,670 tons as compared with 6,777,357 tons during the same period last year. The docks will be kept open for at least another week and possibly longer. One of the loading machines was stopped Dec. 5 but the other loader will be kept going, as the Ford Motor Co. will continue to ship coal from lower lake ports to Detroit as long as Lake Erie is free from ice.

Production is increasing in eastern Ohio. The Barton Coal Co. mine at Taggart has been placed on full time, after being operated three days per week for a few weeks. The Bixler Coal Co. has opened its Cochran mine, which had been idle for several months. This will be operated full time. The Jefferson Coal Co. has started operations at Mines No. 1, 2 and 3, on Piney Fork, which had been idle for months, and the announcement is that they will be operated with a full force. The United States Coal Co. has opened its mine at Plum Run on the New York Central lines and also has put its mines No. 1 and 2 in full operation. The last two named mines are at Bradley and have been operating on part time. The Maher Collieries Co. has opened Mine No. 2, which had been idle for weeks. This is the largest mine in the eastern Ohio field to resume operations.

## OKLAHOMA

Ten miners exploring the Lucky Jew mine near Picher, were injured Nov. 27 by an explosion following the ignition of gas by the open cap lamp of one of the men.

## PENNSYLVANIA

John C. Brydon, formerly president of the Quemahoning Creek Coal Co. and of the National Coal Association, has been appointed vice-president of the Hagey H. Campbell Co., general insurance agents, of Pittsburgh, and resident vice-president of the Commercial Casualty Insurance Co., of Newark, N. J. The appointments became effective Dec. 1.

A new steel tipple for the Adrian mine, now operated by the Jefferson & Indiana Coal Corp. under lease from the Rochester & Pittsburgh Coal & Iron Co. was put into operation Nov. 30. It cost $80,000 and was built in 23 days, which is called a record for speed. The mine now employs 270 men and puts out 1,500 tons of coal a day, the heaviest since 1914.

The power plant and fan house of the Good Clay & Coal Co., located at Johnston's Ridge, about one mile from the village of Bells Landing, was totally destroyed by an explosion of dynamite about 2 a.m., Nov. 28. The mine had been working for some time under the 1917 scale but several weeks ago some trouble arose between the miners and their employers and the mine was shut down. The loss will exceed $25,000. The work was done by one man, the tracks being plainly visible in the soft earth about the place. State police and county detectives are making an investigation.

The Rosedale Coal Co. announced sale of its No. 2 mine, at Poland, in Greene County, to Ben Evans, of Fairmont, W. Va., on Nov. 18. It will be operated under the name of the Evans Coal Co., with main offices in Fairmont. The property is a complete mining and tipple plant with 763 acres of coal land valued at about $750,000, according to John L. Hatfield, president of the Rosedale Coal Co., but has been operated at only part capacity for several years, the Rosedale company concentrating most of its activity on the No. 1 mine, near Morgantown, W. Va. The new owners are considering enlargement of tipple facilities to increase production, which is 10 railroad cars daily at the present time.

Decision has been reached at Harrisburg by the state sanitary waters board that no objection will be made to the removal of culm from banks of streams in the anthracite field by means of steam shovels but that the removal of culm by washery or wet process will be considered stream pollution and will not be tolerated. It is understood that the decision was made in regard to plans for the removal of culm from a Delaware & Hudson right of way near Carbondale, where it is said that there are several hundred thousand tons of culm that may be reclaimed and prepared for market.

## UTAH

The Peerless Coal Co., Newhouse Building, Salt Lake City, following the dispute with its local retail agent, the Marsh Coal Co., has purchased the old yard of the Central Coal & Coke Co. and will go into the retail business in Salt Lake City. The Peerless Coal Co. is owned by the Murdock interests and is one of the more important coal-mining companies with headquarters in Salt Lake City.

L. E. Adams, of the sales department of the Spring Canyon Coal Co., Salt Lake City, has been appointed head of the department, succeeding the late J. A. Stallings, whose death occurred recently.

## WASHINGTON

Extensive experiments with Washington coal to determine its most efficient application to industry is planned by the U. S. Bureau of Mines in co-operation with the College of Mines of the University of Washington. Owing to the nature of the coal beds, a great deal of waste in the form of fine coal is experienced. The mining experts hope to find new uses for this fine coal, but also will study the specialized uses of other grades and qualities of coals. At present the fine coal is used extensively for briqueting.

## WEST VIRGINIA

Deeds placed on record in Fairmont and Morgantown Dec. 4, show that Edward H. Thomas, treasurer of the Hines Lumber Co., of Chicago, sold 4,000 acres of Sewickley coal land and between 500 and 600 acres of surface land along Indian Creek, in Monongalia and Marion Counties, to the Continental Coal Co. of Fairmount for $467,000. Most of the coal land lies in Marion County.

Union leaders in the Scott's Run field of Monongalia County were surprised, according to their own version, when the Golden mine of the By-Products Coal Co., which was leased by Scatchell Brothers from the Watson interests, was placed on a non-union basis early this month. The mine had been idle for some time but when the miners were offered 45c. a ton for their labor in preparing to resume, some of them ceased work. The lessees then decided to operate the mine independent of any agreement with the union. The property at Osage upon which the union miners' barracks were built more than a year ago is owned by the Scatchells.

Mines on the Monongah and Charleston divisions of the Baltimore & Ohio R.R. loaded 1,796,800 net tons of coal to the lake docks this season. Most of this coal originated at mines on the Monongah Division.

George Gaskill has been made superintendent of the Parker Run mine of the Fairmont & Cleveland Coal Co., at Rivesville, one of the largest mines in the region. He succeeds J. W. Bischoff, formerly of Elkins, who went to Montgomery to be superintendent of the mine of the Kanawha & Hocking Coal & Coke Co.

Junior mine of the West Virginia Coal & Coke Co. resumed recently in the Elkins section with M. Benton Mitchell, formerly connected with the Bethlehem Mines Corporation, as superintendent.

Presterly B. Robinson, who was superintendent of the Elk Horn Coal Corporation's mine at Interstate, has accepted a position as superintendent of Hughes mine of the Robinson Coal Co.

The Long Coal Mining Co. resumed operation at its Gladius mine in the Clarksburg section recently on a non-union basis. L. R. Collins, a mine engineer, is now superintendent.

C. D. M. Kramer, of Clarksburg, has been appointed a district state mine inspector, but thus far has not been assigned to any particular district.

It is reported that within a short time Robert M. Lambie, of Charleston, chief of the West Virginia Department of Mines, will announce the appointment of five division safety inspectors. All of the men are the product of the school of engineering of West Virginia University in Morgantown. L. S. Magee, of Morgantown, will be inspector assigned to Monongalia, Marion and Harrison counties. It will be the duty of these men to instruct the men around the mines in safe practices, first-aid and mine-rescue work, according to reports.

Prof. Charles E. Lawall, of the mining engineering department of West Virginia University, has called the annual conference of mining extension instructors in the field for Dec. 21 and 22 in the McClure Hotel, in Wheeling. The instructors will visit the mine of the Windsor Power Co., said to be the largest mine in the state, producing more than 4,000 tons in eight hours.

The Lick Fork Coal Co., operating on the main line of the Virginian near Mullens, in Fayette County, has been reorganized and will be known in the future as the Hysteam Coal Co. The mines of the old company were out of commission for a number of months. Since the reorganization production has been resumed.

The recent purchase of the Low Moor Iron Co.'s mining operations at Kay-Moor and the coal lands of the Coal Land Co. by the Berwind-White interests for $1,001,000 is reported to be a part of the policy of the Berwind-White concern to acquire the larger part of the coal holdings fronting the New River. It is stated that overtures are being made to acquire the holdings of the Stover Coal Co. located not far from the Low Moor property. The Coal Run Land Co., through Josiah Low, president, received $150,000 for two tracts of 1,684 acres of fee land and 407 acres of mineral in the transaction. Frank Lyman, president of the Low Moor company conveyed all interests in approximately 3,000 acres, of which about one-half was in fee, in this transaction, for $851,000.

The Marcus tipple of the Upland Coal & Coke Co., at Elkhorn, contract for which was awarded to the Roberts & Schaefer Co., Chicago, is rapidly nearing completion. This tipple will be completed with retarding conveyor, Marcus screen, and "RandS" shaker loading booms.

## WYOMING

For the first time in more than four years a fatality occurred in the Blairtown properties of the Lion Coal Co. on Nov. 27, when Theodore Poupakies, a miner, was killed by a fall of roof rock. This was the first death in four months in the Rock Springs district, in which several thousand men are employed.

John A. Smith, safety engineer of the Union Pacific Coal Co. at Rock Springs is spending ten days in Pennsylvania at the Bureau of Mines station at Pittsburgh and the Bureau's experimental mine at Brucetown. His time will be taken up with the study of rock-dusting methods.

The U. P. First Aid Association celebrated its 16th anniversary Nov. 21 with a banquet and dance. This association is the most active in southern Wyoming and is at present holding weekly classes in first-aid and mine-rescue work.

At the November meeting of the Rock Springs chapter of the Rocky Mountain Coal Mining Institute, embracing membership in Rock Springs and the surrounding camps, E. H. Denny, of Denver, district supervising engineer for the Bureau of Mines, addressed the meeting upon general mining conditions, with particular reference to the use of rock dust throughout the United States as a preventive of coal-mine disasters.

## CANADA

Twenty-six miners were arraigned before Judge Boyle in the Criminal Court at Calgary, Alta., on Nov. 30 on charges arising out of the strike at the Drumheller coal mines last summer. Eight are charged with unlawful assembly to compel certain persons to abstain from working and to compel the Alberta Block Coal Mining Co. to abstain from employing any persons not belonging to the United Mine Workers. Seven are charged with watching and besetting the Alberta Block mine.

Coal output in British Columbia during the first ten months of this year was 393,040 tons greater than for the corresponding period of 1924, according to a statement by the provincial Department of Mines. Output by districts during the first ten months of 1925 was: Crows Nest Pass, 727,350 tons; Nicola-Princeton, 136,925 tons; Vancouver Island, 1,140,169 tons a total of 2,004,599 tons. For the first time within the last two years nearly all of the Vancouver Island collieries are operating at capacity. A large amount of exploration is being done in the Princeton district and several promising coal prospects recently have changed hands.

The Ontario Government will bend every possible effort to obtain as soon as possible the remaining 6,000 tons of Alberta coal still due that province under the contract entered into by the Alberta, Ontario and federal governments through the Canadian National Rys., Charles McCrea, Ontario Minister of Mines, stated last week. About 19,000 tons of coal was received out of the 25,000 tons trial order prior to the railway withdrawing its cars for the grain movement. "The grain movement should be pretty well completed by the middle of December," stated Mr. McCrea. "We are taking the matter up with Sir Henry Thornton, first as to the balance of the 6,000 or 7,000 tons shipment, and, secondly, to see if, under the conditions now existing, this tonnage could not be increased."

# Traffic

### Sanctions New Coke Rates In New York

The New York Public Service Commission has approved new rates of the New York Central (East) on coke and coke breeze from Harriet to New York Central (West) stations: Fredonia, $1.39; Falconer, $1.76 per net ton; no joint rates heretofore in effect; effective Dec. 22, 1925.

Also of the New York, Chicago & St. Louis R.R. on coke, and coke breeze from Buffalo and Buffalo Junction to Falconer (on Erie and New York Central), $1.76, and to Fredonia (on New York Central), $1.39 per net ton; no joint rates hitherto in effect; effective Dec. 19.

The Commission has approved a new rule of the New York, Ontario & Western R.R. governing diversion or reconsignment of coal and coke so as to make the same applicable on coke breeze, dust and screenings. The new regulation provides mileage charges to apply for excess haul when shipments are out of direct route; effective Dec. 22, 1925; P. S. C. No. 4804.

# Obituary

**Isaac G. Hall**, 40 years old, well known coal man of Indianapolis, died at his home Nov. 29. He had been in ill health for several months, but remained actively in business as an officer of the Knox Consolidated Coal Co. until two weeks before his death. Mr. Hall was born in Brazil., Ind., and was educated at Purdue University. In addition to his connection with the coal company he was a director of the First National Bank at Brazil.

**John Quincy Dickinson**, pioneer in the industrial development of the Kanawha Valley and Southern West Virginia, died at his home in Charleston, W. Va., Nov. 26, after an illness of several years. He was the father of John L. Dickinson, Charleston banker, and of Charles C. Dickinson, who has extensive coal interests. He early recognized the value of coal lands in the Kanawha Valley and acquired extensive holdings of coal, gas and oil properties in Boone, Kanawha, Fayette and Raleigh counties. He also was extensively interested in a number of coal mining companies but in his later years turned the management of these interests over to his sons.

## Coming Meetings

**New River Coal Operators' Association.** Annual meeting, Dec. 17, at Mount Hope, W. Va. Secretary, S. C. Higgins, Mount Hope, W. Va.

**Chicago Wholesale Coal Shippers' Association.** Annual meeting, Great Northern Hotel, Chicago, Ill., Jan. 6, 1926. Secretary, G. H. Merryweather, Temple Bldg., Chicago, Ill.

**American Wood Preservers' Association.** Annual meeting, Jan. 26-28, 1926, at Cleveland, Ohio. Secretary, E. J. Stocking, Chicago, Ill.

**Coal Club of Philadelphia.** Annual meeting, Jan. 28, 1926, at the Bellevue-Stratford Hotel, Philadelphia, Pa. Secretary, C. K. Scull, Philadelphia, Pa.

**American Institute of Electrical Engineers.** Annual convention, Feb. 8-12, 1926, at Engineering Societies Bldg., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Companies

**The Fairplay Coal & Development Co.**, with a capital of $75,000 has been incorporated at Excelsior Springs, Mo. The company will operate coal mines and buy and sell coal. The incorporators are J. D. McDermott, George W. Maidment and Preston Denton.

**The David Thomas Coal Co.**, Columbus, Ohio, has been chartered with an authorized capital of 100 shares, no par value designated, to operate a mine in West Virginia. Operations will start as soon as work is completed on the placing of new equipment in the mine, which will have a capacity of 200 tons daily. Temporary offices will be located at 1113 Bryden Road, Columbus. David R. Thomas is president of the concern. Other incorporators are: David S. Thomas, Walter L. Thomas, Warren H. B. Thomas and Mary A. Thomas.

**The Red Star Coal Co.**, of Whitesburg, Ky., on Nov. 24 filed articles at the State Secretary's office, Frankfort, Ky., capital being $10,000. Alex Taylor, Frank Grimes and W. T. Taylor are the incorporators.

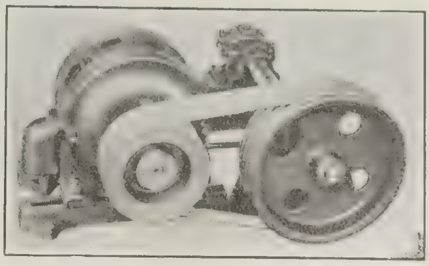
## Industrial Notes

W. J. Nugent, vice-president and general manager of the *Nugent Steel Castings Co.*, Chicago, has been elected president to succeed Charles Piez. Prentiss Coonley was elected vice-president and C. A. MacDonald, secretary, was elected to fill a vacancy on the board of directors. Mr. Nugent has been associated with the company since 1918, when the present plant was erected. From 1918 to 1921 he served as vice-president and in 1921 became general manager as well. It is announced that there will be no change in policy as a result of the recent changes in officials. The interests of Mr. Piez have been taken over by Mr. Nugent and others. The company was organized in 1916 and has made electric steel castings since its inception. A large electric annealing furnace of reciprocating type was recently installed and the entire output is now annealed in this furnace.

Robert Wolfers has joined the **McGraw-Hill Co.** and will be in charge of directories, lists and a direct-mail department which is being developed to serve McGraw-Hill advertisers. The E M F Electrical Year Book recently was purchased. Other McGraw-Hill reference publications are McGraw Central Station Directory, McGraw Electric Railway Directory and the Radio Trade Directory. It is planned to extend the directory and list services into other industries now served by McGraw-Hill publications. Mr. Wolfers was formerly connected with the Automobile Trade Directory and Chilton Automobile Directory. J. S. Cortelyou, who for the last year has been devoting his time to the Radio Trade Directory, will in future direct the compilation of all McGraw-Hill directories and lists. Mr. Cortelyou was associated for many years with Mr. Wolfers in the automotive directory business.

# New Equipment

## Short Coupled Texrope Drive Smooths Transmission



**Model of New Drive**

This means of power transmission is practically a cross between an English rope drive and that employed on many an automobile to operate the fan. The utility of both of these types of drive has been thoroughly proven by long hard usage, the one for transmitting large amounts of power and the other in operating over extended periods under the most trying conditions, subjected to grease, dirt and neglect. Coming of such parentage this drive should prove of high utility.

A new development in the field of power transmission recently has been announced by the Allis-Chalmers Manufacturing Co., of Milwaukee, Wis. This firm has perfected a short-center, flexible drive, known as the Texrope. This consists of two grooved sheaves and a number of specially constructed endless "V"-belts. The sheaves are set at such a distance apart that the belts fit the grooves with neither tension nor slack. In outward appearance this drive strongly resembles the well known English rope drive, except that the place of Manila rope is taken by the "V"-shaped fabric and rubber belts.

Inasmuch as the new type of belts just fit the sheaves, there is no slack or lost motion in the drive. Because of the "V" construction, also, slip of the belts upon their pulleys is minimized, since the harder the belts pull the more firmly do they grip in the grooves. Being somewhat elastic, they cannot jerk, either in starting, accelerating or running, neither can they transmit vibrations, but act as cushions between the driving and driven pulleys. This results in a smoothness of transmission, seldom, if ever, previously attained.

Inasmuch as there is no tension on the belt, the bearing pressures are low and the drive occupies extremely small space. It is silent, clean, unaffected by either moisture or dirt, safe, simple and trouble proof. As the slip is small, the speed ratios are approximately fixed. The drive is durable and each belt carries its proportional share of the load.

These drives range in size from ½ to 250-hp. each, with ratios up to 7 to 1. Belt speeds range from 800 to 6,000 ft. per minute. Drives of this kind have been applied to almost every industry. They are particularly applicable to textile machinery, fans and blowers, machine tools, refrigeration, mining, crushing, wood and metal-working machines, elevators and conveyors, and similar contrivances.

**The Climax Engineering Co.**, Clinton, Iowa, announces the appointment of T. L. Keeling, as Sales Representative for Ohio, western New York, and western Pennsylvania, with offices at 657 Leader Building, Cleveland.

## Publications Received

**Power-Plant Lubrication**, by Wm. F. Osborne. McGraw-Hill Book Co., Inc., New York City. Pp. 275; 5½x8 in.; illustrated. Price, $3. A practical book for the power-plant engineer explaining the physical and chemical properties of lubricants, their action under changing influences of heat, pressure, etc., and the methods of determining their relative value.

**Alternating-Current Circuits**, by John M. Bryant and James A. Correll. McGraw-Hill Book Co., Inc., New York City. Pp. 405; 6x9 in.; illustrated. Price, $4. This book is intended as an introduction to the study of alternating-current circuits and transmission lines.

**Analyses of Alberta Coal**, by Edgar Stansfield, Robert T. Hollies and William P. Campbell. Scientific and Industrial Research Council of Alberta, Edmonton, Alta., Can. Pp. 63; 6x9 in.; illustrated.

**The Case of Bituminous Coal**, by Walton H. Hamilton and Helen R. Wright, with the aid of the council and staff of the Institute of Economics. The Macmillan Co., New York City. Price, $2.50. Pp. 307; 5x7½ in.; illustrated.

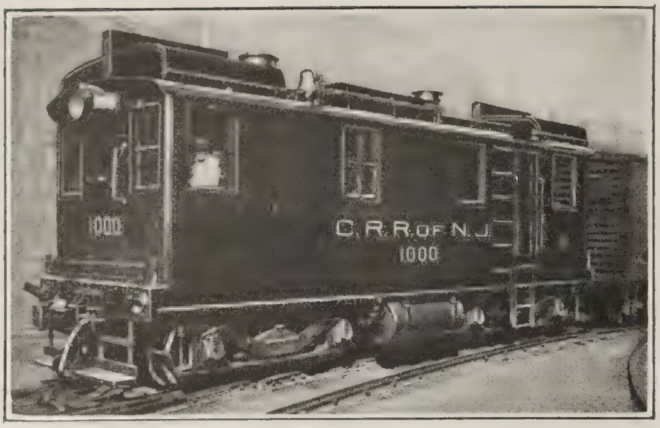
**Annual Report of the Director of the Census to the Secretary of Commerce for the Fiscal Year Ended June 30, 1925.** Pp. 34; 6x9 in.; tables.

**Annual Report of the Secretary of Commerce.** Pp. 43; 6x9 in.

## Thermo-Electric Locomotive Obviates Smoke

Recent years have witnessed a gradual decrease of steam in all industry. A recent advance in railway engineering is represented by the development of a locomotive driven by an oil engine through the medium of an electric generator and motor. The Central Railroad of New Jersey recently purchased a 60-ton machine of this kind and was followed closely by the Long Island R.R. with a 100-ton machine. Other railroads are also trying out oil-electrics. If service performances of these locomotives bear out their demonstration performances, it may possibly foreshadow a wide substitution of the oil-electric locomotive for the steam engine in railroading throughout the United States, in the operation of coal company short lines and yards and in haulage about strip pits.

In the construction of one type of these locomotives the oil engine, which is the product of the Ingersoll-Rand Co., has six vertical cylinders operating on the four-stroke cycle. Fuel oil is injected directly into the cylinders under pressure and is ignited by the heat resulting from the compression. The action of the engine is similar to



**In the Switching Yard**

This 60-ton locomotive is built to attain a speed of only 30 m.p.h., with a draw bar pull of 36,000 lb. Machines of this kind can, of course, be designed with equal facility for higher speeds. The thermo-dynamic efficiency attained with this machine is from three to five times that of steam locomotives.

that of an ordinary automobile engine with the heat of compression doing the work of the spark plug. Forced lubrication is employed and circulating water is distributed to all parts of the engine by a centrifugal pump.

Directly connected to this oil engine is a General Electric generator, the voltage of which ranges from 200 to 750. The output of this machine is regulated by the throttle control of the engine. The framework or chassis is built by the American Locomotive Works.

Control of a locomotive of this kind is extremely simple, being centered in the manipulation of two levers. One of these serves as a throttle for the engine, while the other is a master controller or electric switch which places the tractive motors either in series or in parallel as circumstances may require. Tractive efforts may be varied to suit any operating condition.

Performance records of these locomotives show that they are far more economical in cost of operation than steam-driven machines of like capacities. The thermal efficiency, as referred to the effort delivered to the driving wheels, ranges from 25 to 27 per cent, as compared with from 5 to 8 per cent in steam locomotives. The engines used by the Central Railroad of New Jersey and the Long Island R.R. have been designed and constructed for slow speed switching service. The 60-ton machine develops 300 hp. and is capable of traveling at 30 m.p.h., exerting a tractive effort of 36,000 lb. The larger machine is of 600 hp., travels the same rate per hour, but has a draw-bar pull of 60,000 lb. Machines of this type may, however, be designed for high speed road service with equal facility.

## Big Fuse Puller Will Not Twist or Slip

The Trico Fuse Manufacturing Co., of Milwaukee, Wis., makers of cartridge fuses, announces the addition of a "Giant" fuse puller and replacer to its present model, the pocket-size tool. The giant-size fuse puller is the big brother to the pocket size puller and it has been aptly termed a "brute for strength." It is 12 in. long and made with seven laminations of the finest genuine gray horn fibre, securely riveted at all points subject to strain. Inserts placed between the laminations provide a firm, even grip on the fuse and prevent any tendency to twist or slip in the hands of the user. The puller and replacer is designed for use on fuses from 100 to 600 amp. at 250 volts and 60 to 400 amp. at 400 volts, making it an ideal tool for safely and conveniently handling fuses of large capacity.

**Makes Fuse Pulling Safe**

Seven laminations of fibre securely held together prevent this device from twisting.

## Hood with Respirator Protects Worker

In many occupations dust or fine particles of other matter pervades the air in large quantities. These particles, if inhaled, cause serious discomfort to the worker if not even endangering or impairing his health. Before a workman may safely breathe such an atmosphere it is necessary that the dust or other particles be screened out of it. To accomplish this result the Engineering Products Corporation of New York has placed on the market the dust mask shown in the accompanying illustration.

This mask consists essentially of two parts or elements namely, a dust proof hood and a respirator. The hood is made of a closely woven washable twill that fits down over the shoulders, but allows free movement to the arms. At the neck it is provided with a gathering string or strap which may be drawn up effectively excluding all dust that might find its way under the hood skirts. This hood may readily be washed or otherwise cleaned without injuring its fabric or impairing its efficiency.

The respirator is made up of spun and cast aluminum, the cushion touching the face being made of rubber. The tape or strap drawing the hood about the neck also draws the respirator firmly against the mouth and nose. The flutter or exhalation valve is attached to the bottom of the respirator preventing the exhaled air from fogging the sight lenses. The strainer element is made up of a series of felt disks the exact number of which is governed by the size of dust particles encountered and their density in the air. The vision lenses are of nonshatterable, clear, two-ply, laminated glass. They are held in their machined, cast aluminum receptacles by means of spring clips.

Because of the materials of which this equipment is made as well as the care in detail with which it is manufactured this dust mask is extremely efficient in use. If forms an effective protection for the wearer when working in an atmosphere laden with sharp abrasive dust that would irritate the lungs or one filled with fine particles or globules of paint, varnish or enamel as that encountered when using a paint spray or gun, and which may have an equally detrimental effect upon the organs of respiration.

**No Fine Ashes Penetrate This Man's Lungs**

Blowing down the tubes of a boiler is often an extremely dusty job, and the ash dust encountered is sharp and abrasive and highly irritating to the lung tissues. Use of this dust mask precludes all possibility of such particles entering the workman's respiratory organs, no matter how thick may be the cloud of it in the air breathed.

## Recent Patents

**Mining Machine**; 1,552,909. Harry L. Brown, Glen Ridge, N. J. Sept. 8, 1925. Filed May 22, 1922; serial No. 562,829.

**Coking-Retort Oven**; 1,553,662. Joseph Becker, Pittsburgh, Pa., assignor to the Koppers Co., Pittsburgh, Pa. Sept. 15, 1925. Filed June 11, 1921; serial No. 476,677.

**Coal-Loading Bucket**; 1,554,164. Norman H. McClevey, Petersburg, Ind. Sept. 15, 1925. Filed July 14, 1924; serial No. 725,852.

**Loading Machine**; 1,554,725. Isidor S. Hochreiter, Luzerne, Pa. Sept. 22, 1925. Filed Feb. 19, 1923; serial No. 619,943.

## Pinchot Prolongs the Strike

FOR A MAN who professes to be so ardent in his desire to effect an immediate resumption of anthracite mining, the Governor of Pennsylvania pursues strange means to achieve his ends. To the ill-timed folly of his conference of Nov. 28 he now adds the call for a special session of the state legislature to consider, among other things, the enactment of measures to declare anthracite mining a public utility and place the industry under state control.

In the light of the terms presented to an emissary of the union by the operators—terms of which Mr. Pinchot must have had full knowledge before making public his "peace" program—the presentation of that program could have but one result. That result was to drive operators and miners, who were nearing a common ground, farther apart. This would probably have been true even had the Governor's program had real merit; any outside interference at such a stage would have endangered negotiations: with Pinchot's eleven points what they were, their rejection was inevitable.

The chances of a speedy rapprochement—not overly bright after that flare-up—are now still further postponed by the Governor's threat of regulation. By that action he definitely and openly aligns himself with Mr. Lewis and the union cohorts. The thin mask of impartiality with which he had covered his earlier unwelcome participation in the situation is dropped. Under a guise of acting in the public interest, Mr. Pinchot in effect says to Mr. Lewis: "Don't worry, John; if the operators won't yield willingly to our terms of surrender, I'll swing the big stick over their heads and make them wish they had."

Under such an implied promise will it be strange if the strikers take new heart and resolve to turn a deaf ear to reason until the success or failure of the threat has been determined? Hardly. Mr. Pinchot offers them chimerical hope where there had been darking despair. But what of the public for which the Governor has expressed such sympathy? What of the business interests of the anthracite region whose future has been so dear to Mr. Pinchot's heart? How will these interests, how will the public at large be served by steeling the miners to refuse honorable terms of peace—terms which only ask them to justify their demands before an impartial board of arbitration?

This is the question of immediate importance. The sequence of events, the background against which the proposals for legislative control have been projected make it distressingly plain that those proposals are brought forward, not to be considered on their dubious merits, but to bludgeon the operators into accepting the Governor's "peace" program of Nov. 28. To accomplish that Mr. Pinchot seems willing to block a settlement for months since he cannot expect that the responsible leaders of the industry are so spineless or so blind to the best interests of the public as to meekly swallow his "peace" program or his campaign of legislative reprisals. The Governor of Pennsylvania, therefore, must now shoulder the responsibility for prolonging the anthracite suspension.

## Making Headway

PLACING THEMSELVES at the head of the procession and looking back at the train behind, the critics of the coal industry question why it is that some of the travelers are ahead and some in the rear. We would suggest that the reason why there are leaders and stragglers is because there is progress. Sanford E. Thompson in the United States Coal Commission report and in a lesser degree Walton H. Hamilton and Helen R. Wright in their book just published on "The Case of Bituminous Coal" are examples of such critics. They have their place in the human economy of course. They are advocates of higher purposes, but it might be well if they realized that inequality in practice is not so much an evidence of inertia as a sign of progress. There is no inequality, for instance, in India's native industries. So long as there is a fore and an aft in the progress of the coal industry, we may be sure that it is progress and not stagnation we are viewing.

In what industry have revolutionary changes come in a night? Are all the isolated power plants, for instance, burning coal in the most modern of boilers? Has not the return-tubular boiler persisted for thirty or forty years despite many radical changes in boiler practice? Did the mechanical blowing of glass invade the window-glass industry in a few short years or did it take a decade? Did flotation come in a year in the metal industry, or was it an affair of long continued growth? In the late war we sweat blood to get ready for battle and when we got our men to the front they had to fight with guns bought from the Allies. Secretary Davis has said that without such help our men could not have withstood the enemy for a single hour. Why? Because industry cannot be mobilized in a year or so to make these marvelous changes. The manufacturer cannot provide the facilities even if the consumer is ready to purchase them—even when we have mastered the new technique and know just what we want and just what to do with it when we have it.

In no industry is progress as rapid as it should be. It certainly is not as fast as might be desired in the coal industry, but we have yet to think that the bituminous-coal industry should be held up to public reprobation for its dilatoriness in this respect, especially in the matter of loading machines.

THE PAPERS DECLARE that the miners made concessions in accepting Mr. Pinchot's offer, but the truth is they conceded nothing, they merely reduced some of their demands. It is the operator who is being asked by Mr. Pinchot to make the concessions.

## Planning Public Relations

IN ALL INDUSTRIES the consumers are more numerous than the producers, and if there is conflict the consumers have the power and the vote to mold legislation to suit their wishes, subject only to constitutional law. So it is well for the producers to think first and correctly, lest the action of the consumer be unfortunate for the producer.

Most industries are giving thought to this condition and asking themselves just what course will satisfy the consumer or, as it is more usually put, the "public." The producers, wholesalers and retailers of coal would do well to keep this same question of public relations constantly in view.

When a severe difference of opinion, a quarrel in fact, exists between two persons it is amazing how almost impossible it is to avoid controversy, because every expression is either misinterpreted or misquoted. If the operator declares, for instance, that there will be a coal shortage, he is told that he is trying to create a panic so that he may sell more coal and sell it at an extortionate figure. If he says nothing and a shortage comes, he is accused of lulling the public to sleep so that he can get the public into a trap and make unreasonable profits. The accusation will be even more bitter if he declares that there is no reason to fear a shortage.

If he builds a store or a town he is accused of feudalism and an attempt to victimize his employees and if he decides he will neither enter the store business, nor construct a town, he is reproached with an indifference to his employees' needs and with the fact that his workmen are not living in decent houses or are being victimized by third parties with whom the operator is said to be in collusion.

The trouble with such criticism is that it is always hard to refute. It is always difficult to show that the action or non-action was not the outcome of an evil intention.

It is important for an industry to be on proper terms with the consumer of its products. What the coal industry needs is to have the public assured that it is working for safety, the happiness and health of its employees, for steady operation, for a satisfactory supply at all times of the necessary fuel supplies and for the production of fuel that is clean, suitably sized and sold at a fair price. To this end the industry should be willing to let the public know the actual facts. To hide them will only result in suspicion.

The public bases its judgment on the actions of individuals. A nation is condemned for the action of one of its nationals, a race for the evil deeds of one of its members, an industry for the business methods of one of its merchants. It is, therefore, necessary to create a right sentiment in the industry, a correct standard by which the many operators may judge the actions of others and may themselves judge of their own actions. There must be instant condemnation of violations of these standards. In the words of our British cousins there must be certain things that "are just simply never done, don't you know."

We cannot show a lenient judgment to the man who runs an unsafe mine, builds or maintains rows of shacks, hires enough men to mine twice as much coal as he can sell, sends dirty, unsized coal to market or sells coal at unreasonable price at a time of scarcity. To condone such offenses is to make "coal man" a byword, to bring merited contempt on the industry.

No one who is in a line of business for life, who has his capital invested in it, can see individuals bringing it in disrepute without a feeling of indignation and regret. The health of industry depends on the honesty of its decisions, and no man who has devoted his life and his capital to an industry can be other than sensitive as to its honor. To a good man, his industry is only second to his country and the good name of his product only second to the honor of its flag.

## Quantity Designing

IN MOST large companies equipment is installed in many ways—some good, some bad, according to the ability of the man on the job—and if it is discovered that the design of some detail is not of the best it is probably not corrected, because it would be expensive to tear it down and re-erect it, the reconstruction would reflect on someone, delay operation and perhaps might cause a lengthy dispute.

All these questions of how any piece of apparatus should be installed should be settled once and for all by standards. The best and safest way should be determined after careful inquiry and perhaps after study of records, exhaustive tests, correspondence and discussion. Men in other and kindred industries may be consulted and the standard practices of other companies examined.

The Union Pacific Coal Co. has by some such means adopted tentative standards for its mines. Other mines may need slightly different rules and the company does not itself believe that it has made standards that cover all equipment, all contingencies or that are the final word even for its own conditions.

To make these standards a mining engineer was specially appointed having no other duties to distract his attention. He consulted with the operating and engineering staff and visited the mines to ascertain the specific conditions to be met.

Every working copy of the standards has been numbered serially and a receipt requested of mine superintendents, mine managers, foremen and others, and this receipt is intended as a recognition on the part of the recipient that having given the standard due consideration, he recognizes its desirability and is prepared to make it a guide in his future work. Time will show what changes are needed, and every sheet is a loose leaf that can be replaced by another if experience, new equipment, study or a changed condition should dictate.

*Coal Age* takes pleasure in being the vehicle by which these standards may be available to its readers. It is hoped that it will serve to formulate the ideas of the industry as to details of installation.

A mine does not manufacture equipment but it puts it into place, it prepares for its placing, it assembles and it operates it. For this purpose it should have, in a degree, quantity design and quantity methods as the manufacturer has quantity production. Unfortunately, hitherto most installations have been placed as if they were the first of the kind ever planned. No past experience has been invoked, no records, no study. The installer, if he has time, searches only his own intelligence and, often being rushed, leaves the matter to a subordinate. This way lies failure.

To avoid such untoward results the standards which will appear beginning with this number were devised and issued, and the Union Pacific Coal Co. takes pleasure in placing them at the service of the industry.

# Many Mining Men Discuss Today's Coal Problems In Coal Mining Institute of America

## Underground Conveyors and New Methods of Using Them Prove Absorbing Subjects—Loading Machines Are Much at the Fore—Institute Sees Explosions in Bruceton

**By R. Dawson Hall and Alphonse F. Brosky**
Engineering Editor and Assistant Editor of *Coal Age*

THE AUDITORIUM in the Chamber of Commerce building, Pittsburgh, Pa., did not quite accommodate the large number of men who flocked to the thirty-ninth meeting of the Coal Mining Institute of America, Dec. 9, 10 and 11, to hear about and discuss the changes, that are being, and ought to be, made in the bituminous mining industry—mechanical loading and conveying, unique recovery methods of old abandoned Big Vein pillars, modern practice in underground substations, timber preservation and reforestation by coal companies and other subjects which were slightly less fully covered by discussions of questions from the floor. The last day of the meeting was set aside for an inspection trip to the Bruceton experimental mine of the Bureau of Mines where various tests were staged to remove any doubts of members regarding the dangers lurking in coal mines and the effectiveness of safety practices as a means to avoid them.

Following the custom of past years the Institute opened with a business session which lasted a scant one hour. Secretary H. D. (Joe) Mason quickly disposed of reports of activities during the year and then turned to news. The assets of the Institute at the opening of the meeting amounted to $2,128.45; seventeen members died during the year; the membership was increased by 192, bringing the total up to 3,021; Joseph Williams and Joseph Knapper, two veteran mine inspectors, were proposed for honorary membership. Mr. Mason announced that Scott Turner, the new director of the Bureau of Mines, has been elected automatically as an honorary member in accordance with the tradition of the Institute. The report of the board of tellers an-

**W. C. Hood**

New president of the Institute and assistant general superintendent of the H. C. Frick Coke Co.

**A. C. Fieldner**

Chief chemist of the U. S. Bureau of Mines and Superintendent of the Pittsburgh Experiment Station.

**J. J. Rutledge**

Elected second vice-president of the Institute. He is chief engineer, Maryland State Bureau of Mines.

**Nicholas Evans**

Retiring president of the Institute. He is mine inspector of the 24th bituminous district of Pennsylvania.

nounced the following election of officers President, W. C. Hood,, assistant general superintendent, H. C. Frick Coke Co., Uniontown, Pa.; first vice-president, Frank R. Lyons, vice-president in charge of operations, Consolidation Coal Co., Fairmont, W. Va.; second vice-president, J. J. Rutledge, chief engineer, Maryland State Bureau of Mines, Baltimore, Md., and third vice-president, N. D. Levin, chief engineer, Jeffrey Mfg. Co., Columbus, Ohio. Mr. Mason was re-elected secretary and treasurer for the ensuing year.

The opening address by President Nicholas Evans dealt with the success of the Institute and pointed to the things which must be done in the future to insure its advancement. He declared the Institute cannot stand still; it must advance and make progress if it is to live. It has seen progress, from mule to rope, and from rope to electric haulage and must make further changes for the better by co-operation in research. It already has given its moral support and expects to contribute more actively henceforth.

# Underground Mechanical Loading Makes Progress

Mechanical loading was discussed in the first paper of the day by Walter M. Dake, mining engineer, Joy Machine Co., Franklin, Pa. He said the success of mechanized mining in specific cases will depend upon the attitude of the mine owners and their officials. Without the support of the entire personnel the project undoubtedly will fail. Purchase of the necessary equipment should follow only after a thorough investigation has been made and complete estimates of cost have been compiled. Hourly wage rates for mechanical loading have made the companies put more force behind all innovations. And because loading equipment must of necessity be more complicated than cutters, for instance, intense inspection and careful maintenance are required to avoid breakdowns. Antiquated auxiliary equipment has caused many failures and should have no place in mechanical mining. There is even greater need for co-operation between purchaser and manufacturer than has been displayed in the past. Absolute costs should and must be kept.

In his paper he cited several experiences of companies with mechanical loaders. One firm in a high wage rate field started as early as 1922 and gradually installed six machines of a certain make. Their operation was merely experimental in that the machines were not entirely successful and their weakness developed. But so convincingly were the possibilities of mechanical loading brought home to this company during these early days that it has since installed seven rugged machines of the same make. Following the later installation savings were immediately apparent and as the various operations were stabilized a gradual reduction in costs was effected. In a recent six-month run during which 120,670 tons was produced mechanically, a saving over hand loading of 41.2c. per ton or a total of $49,716, was effected. At that, this company reports a low average rate of 112 tons per machine per shift and the average loading time of only 30 per cent of each shift.

E. H. Coxe inquired whether interest and depreciation were included in the computation of costs by this company. He was informed that these items were not included but that maintenance was. Mr. Dake answered a question relative to clearance, put by D. J. Parker, by saying that timbers must be kept 10 to 12 ft. from the face. J. J. Forbes asked what is being done to allay the dust stirred up by mechanical loaders. The reply was that nothing had been done in this direction with certain types of machine. Inquiry was made of the use of the Joy machine in the Pittsburgh coal seam. Mr. Dake said that two machines of this kind at work in this bed are averaging about 110 tons per shift each; drawslate is gobbed by hand.

Moving pictures of the Joy machine in operation in a mine were then shown. The audience was amused by the speed with which cars were shifted in the picture and was told that only in movies is this being so successfully accomplished.

Some of the accomplishments of the Myers-Whaley loader in coal mine work were reviewed in an interesting paper by Charles C. Whaley of the Myers-Whaley Co., Knoxville, Tenn. He described conditions and results attained in one mine paying the high wage scale of the Central Competitive field. The bed averages 6 ft. thick and is overlaid with 6 to 14 in. of clod which falls with the coal. Rooms are driven 36 ft. wide and the coal is undercut and snubbed, and is well shot. A crew of 13 or 14 men, depending upon the quantity of clod which must be handled, and including one foreman, performs all duties incident to mining and loading. This crew in a month of 25 working days placed on the parting an average per shift of 191 tons at a cost of somewhat less than 82c. per ton, including all items, as against a cost of hand loading of about $1.32, thus making a saving of 50c. per ton.

### Keep Airway Clean

He next called attention to an editorial in the Oct. 15 issue of *Coal Age* relative to keeping airways clean. The Myers-Whaley shovel is being used in a number of mines for this work and for taking top and bottom in other entries as well. The first machine of this kind used for lifting bottom was installed in 1922 in a central Pennsylvania mine in the Miller seam which averages about 36 in. thick. The machine lifted 3 to 4 ft. of bottom composed of bastard fire clay which broke in large pieces. Despite the fact that the work of the machine was confined to two dip headings which were wet and where the coal could be mined only one cut in advance of bottom taking, not to mention other difficulties encountered, the machine succeeded in loading, over a wide period, an average of fifty 1½-ton cars per shift, advancing each of the pair of entries 15 ft. per shift. The management reports that the cost of dead work was more than cut in half and the rate of entry advance was doubled. On the merit of these results this company has installed additional machines.

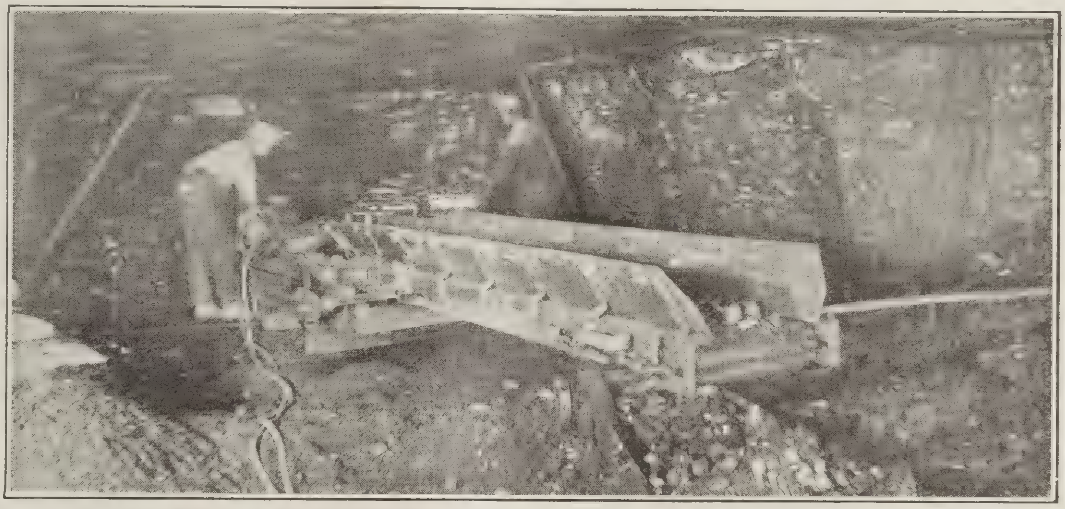
In 1923 another company installed a No. 3 Myers-Whaley for taking top and since has installed five more. Here again the Miller bed is being mined. This averages about 40 in. in thickness and is overlaid by a roof of laminated shale. Entries are driven 11 ft. wide and 3 to 4 ft. of top rock is brushed on all the mains. Coal is loaded by hand in a stretch of about 100 ft. in advance of top taking, throughout which distance permanent track is laid. Roof to the necessary clearance height in this entire stretch is brought down before the machine starts to load. Holes are shot in twos, one near each rib, producing clean breaks. Jackhammers are used for drilling. By this means, barring haulage delays, continuous loading is afforded the machine and the cleanup advances regularly about 65 ft. each shift, the material filling eighty-five 1½-ton cars. The best record is 127 cars per shift. The crew consists of one runner, one helper and one motorman.

This company is using the same type of machines for cleaning up falls in aircourses in the Lower Freeport bed. Here the roof is of fire clay and falls to a height of about 2 ft. above the coal. Track is extended as required in built-up sections 7½ ft. long. Such a section can be added in about 10 min. The crew consists of two men who perform all duties connected with this job. The average loading rate is about forty 1½-ton cars per shift.

At still another operation during last July this company advanced an entry through 1½ ft. of coal and 6 ft. of rock, on a dip of 7½ per cent, with considerable water, 214 lin.ft. in 26 working days. Two crews of 2 men each, performed all the duties including tramming.

**Short Face Loader in Entry**

This machine will load out a place as wide as 35 ft. The rear conveyor reaches sidewise 13½ ft. from the main body of the machine which can also be swung at an angle to give 4 ft. additional reach from the center of the place. By using a face conveyor the workable width can be further increased. This unit cuts and loads coal in an advance of 5 cuts or 30 ft. in a place 15 ft. wide in 8 hr. regularly and has made an advance of 42 ft. in 8 hr.



W. L. Affelder, assistant to the president Hillman Coal & Coke Co., sees real value in the use of the Myers-Whaley for taking top or bottom in low beds and for cleaning up air courses in high ones. He is confident its use will be widened after it is equipped with an explosion-proof motor. Trot Dodson, vice-president in charge of operations, Pittsburgh Coal Co., asked if coal was separated from the rock in the last mentioned application in Mr. Whaley's paper, and was told that it was not. Thomas S. Lowther, mine inspector, Indiana, Pa., said that at the No. 45 mine of the Russell Coal Mining Co. at Clymer, Pa., top rock is taken with a Myers-Whaley in stretches of 200 ft. The rock is brought down 2 or 3 cuts in advance of the machine. The roof is a bastard fire clay that cannot be timbered economically. The machine loads 70 to 110 one-ton cars per shift. W. B. Wardrop, mine inspector, Barnesboro, Pa., pointed to the advantage of uniform head clearance which the machine provides. He stated that one company asserts that the yardage cost has been cut in half by this machine.

Continuing the treatment of mechanical loading devices, A. R. Anderson, Jeffrey Mfg. Co., of Columbus, Ohio, gave a number of results attained by the Jeffrey shortwaloader and conveyor, which equipment has been designed with the purpose in mind of concentrating the workings. None of this equipment is supposed to be moved from place to place after each cut. As an aid to the driving of narrow work the shortwaloader has been developed. This machine both cuts and loads. The average advance being made with it is 30 ft. per shift.

In one mine in 3½ ft. of coal a pair of entries was driven 1,800 ft. in three months by two shortwaloaders which worked single shifts. Breakthroughs were cut by these machines during the advance. In another mine in a 3½-ft. seam one machine cut and loaded 643 ft. in a month of 25½ working days, an average of 25.2 ft. per day. Still another machine advanced an entry 726 ft. in a month of 25 working days at an average of 29 ft. per day. This same machine maintained an average of 33 ft. per shift during 14 consecutive days. The longest advance made in any one day thus far is 42 ft.

Mr. Anderson said that in two mines where the entire output is loaded with shortwaloaders the output per man including everyone in the mine and tipple amounts to 10 tons, or more than double the average of 4 to 5 tons per man attained by the bituminous industry.

He next introduced the Jeffrey 44-B conveyor loader which is at work in several mines. This machine extends along the entire length of the face. As it is only 28 in. wide and 17 in. high, it is applicable to low coal as well as high and is well suited for long face work where timbers must be maintained close to the coal. In one mine where this machine is being used the coal is 3 to 3½ ft. thick. This machine is taking out two cuts on a 100-ft. face per shift. He declared that in high coal two cuts per shift can be taken, yielding a correspondingly higher tonnage.

In one mine the Jeffrey 47-A sectional conveyor is being used on a 300-ft. face. The coal is undercut and shot down on the night shift and loaded by 15 men on the day shift. This crew and equipment has loaded 480 tons in one shift, which is an average of 32 tons per loader. Moving pictures of the equipment described by Mr. Anderson were shown prior to adjournment for lunch.

The afternoon program of the first day was opened by the showing of a motion picture which presented the complete process of manufacturing wire rope in the plant of John A. Roebling's Sons Co.

Then Richard Maize, mine inspector, conducted the discussion on a group of questions, the first of which was "What New Work Has Been Done in Recent Years to Prevent or Reduce Mine Accidents?" William German focused attention on the prevailing dangerous practice of handling black powder in metal kegs. He

**Conveyor on 300-Ft. Face**

Here the sectional type conveyor is used on the face. Fifteen men are stationed at 20-ft. intervals along this face and have loaded as much as 480 tons of 5½ ft. coal in 8 hr. A night crew does the cutting, shooting, etc. Here a room pillar is being slabbed. The practice in this mine is to drive 12-ft. rooms on 95-ft. centers and then to take the pillar by slab cuts until it is only 30 ft. wide.

remarked that Du Pont now offers a black powder in pellet form which is not exposed and, therefore, is comparatively safe to handle.

E. J. Gleim, of the Bureau of Mines, related the work which the Bureau has accomplished during the last two years in testing and approving certain classes of machines and devices which meet the prescribed minimum safety requirements. During this time it has issued 24 new approvals so that now the Bureau's list of permissible equipment is wider and far more complete than heretofore. Prior to Jan. 1, 1924, there were no permissible room hoists, air compressors, mine pumps, power trucks and storage battery locomotives for main line haulage, but now this equipment is on the list. Further additions consist of four types of mining machines, one coal drill, six storage-battery gathering locomotives, five shot-blasting units, one flash light and one methane detector.

Two of the above approvals—the storage-battery power truck and the storage-battery locomotive—provide considerable possibilities for the reduction and prevention of accidents by enabling operation of a mine without the use of feeder circuits.

### Discuss Safety Devices

H. H. Hamilton pointed to a safety blasting cap offered by Du Pont, the two ends of which are short-circuited to guard against stray currents and conducted currents up to 550 volts. H. D. Mason said the most available means of bettering safety is by living up to the compensation laws. A new safety device which automatically keeps sand dry and free-running was described by G. M. Crawford. It is offered by the Safety Electric Corp., of Philadelphia, Pa.

That codes of standardization go a long way toward eliminating hazards and bettering operations was the view presented by R. D. Hall, engineering editor, *Coal Age*. A few remarks were added by S. W. Blakslee, division superintendent, Pennsylvania Coal & Coke Co., Ehrenfeld, Pa., on the two-pointed merit of mechanical loading which affords concentration and, therefore, better supervision and increases the output per man which is not accompanied by any increase in accidents. A. N. Young, superintendent, Hillman Coal & Coke Co., mentioned a practice which has been established in a number of mines of inserting a wooden wedge between the brake lever and the ratchet of a mine car to avoid inopportune releasing of the brake after it is set.

W. L. Affelder believes the colored man is safer than the white because he is timid and cautious and, therefore, is careful. White men have been the victims of every fatal accident this year in one of his mines in which one-fourth to one-third of the men are colored. An issue arose as to the advisability of forcing men to sound roof frequently. Mr. Young explained a rule which one company has adopted requiring officials to compel miners to sound the roof every time an official visits their working place to get them into the habit. Mr. Affelder believes this rule attacks safety from the wrong end, making roof sounding mechanical and compulsory instead of premeditated.

According to E. E. Girod, mine inspector, a number of dusty mines in the southwestern part of the state provide water hose for every working place. He wants to see coal dust settled at the point of origin. Six mines have provided hose for each of their 1,500 workers and two other mines are following the suggestion. In five mines in his district water is applied to the ingoing bits of mining machines. In one of the latter mines coal dust was scarcely noticeable anywhere five weeks after the mine had been rock dusted.

T. G. Fear, general superintendent, Inland Collieries Co., Indianola, Pa., related one of his experiences at an Alabama mine. Here out of five fatal accidents only one victim was a negro despite the fact that 60 per cent of the miners were colored. He claims that superintendents and foremen should be held responsible for accidents to a greater degree than they are. Many accidents occur because of a lack of knowledge of conditions on the part of the management. One company in Pennsylvania having 14 mines provides its underground officials with printed forms in a book in which must be entered the conditions of each working place at each visit. Every two weeks these data are transferred to a master sheet for comparison studies, when various charges are counted. Two charges to any one man calls a warning and three brings dismissal.

The next question asked was whether or not it is an economy to leave a 100-ft. water barrier in mines adjoining worked out mines as in the coke region of Pennsylvania where the coal acreage is high-priced. H. S. Harrok, consulting engineer, of Pittsburgh, Pa., opened the discussion. He is of the opinion that the leaving of such a barrier, which is following precedent only, is a needless waste. He would leave only a 15-ft. pillar to protect ventilation and would pump the water. In a fair-sized mine the loss apportioned over the life of the mine might be as much as 7c. per ton, whereas handling about 3 tons of water for every ton of coal mined (the coke region ratio) would cost only about 2½c.

George Steinneiser, of Punxsutawney, Pa., declared that a 15-ft. pillar would not be sufficiently large to hold in the ventilating currents as it would undoubtedly crush. George S. Rice seconded that remark and called attention to the danger of encountering unexpected bodies of gas in the old workings. Mr. Harrok thinks that even a 100-ft. barrier is unsafe as the exact courses of the boundary of old workings are generally not known, for which reason there is danger of puncturing them. C. P. Bryne, mine inspector, advised drilling as a means of determining the extent of the barrier.

The vicissitudes of the water problem in the anthracite region have in some cases been due to punctured barriers, according to T. M. Chance, consulting engineer, of Philadelphia. He favors the leaving of an adequate barrier of a width fixed by conditions, half of which should lie on each side of the boundary line. He added that the danger of puncturing is removed by accurate mapping. Mr. Hall would donate a recoverable barrier to the mine that handles the water.

### Wood Ties for Steel?

The third question of the day was: "Is the Arcing of Electricity Between Steel Rails and Steel Ties Likely to Cause a Mine Fire?" Mr. Affelder opened and led the discussion. Evidence and subsequent tests following a fire in one of the mines of the Hillman Coal & Coke Co., leads him to believe that a fire can be started in this way and caused him to replace steel ties with those of wood in this mine. The fire referred to occurred at the end of a retreating butt entry, about 200 ft. from the face entry on which had been shifted, before the fire was detected, a large trip of cars by a trolley locomotive which pulled away at a point abreast of the butt entry. He thinks that broken cross bonds outby of the locomotive caused the return circuit to travel only to the end of the temporary track where it arced between the rail and a steel tie, as the butt entry track was bonded on one side only, thus igniting fine coal on the bottom.

He described a condition which might have significance in the case, namely, a cannel coal roof over the coal which is so volatile that it can be lit to a glow with a match and which flakes and falls to the floor.

An investigation disclosed no other possible factors in the fire. A series of tests were staged in which arcing was caused in the manner described. Mr. Rice knows of fires which are assumed to have been started by such arcing in mines where wooden ties were installed. Graham Bright suggested the use of a double-conductor cable where a reel locomotive is used, or a storage-battery locomotive as a means to avoid the arcing. Mr. Affelder said that such provisions would not serve the specific purpose in that no wire extended within 200 ft. of the origin of the fire. Mr. Rice believed the cause was obviously that chosen by Mr. Affelder.

Edwin H. Johnson, mining engineer, Coloder Co., Columbus, Ohio, added a paper to the meeting's symposium on mechanical loading achievements. He sees the greatest future growth in mechanical loading machines in organized fields where it would be utilized as a weapon to reduce the cost differential between high and low wages. He looks for little opposition from the miners' organization whose leaders are ready to support gradual changes which will improve the working conditions of the miner. The surety of economies in mechanical loading at this early date is evidenced by remarks coming from operators in fields where labor is scarce, to the effect that without mechanical loaders they would be unable to maintain their present level of production.

He referred to a new factor in mechanical loading, namely, machine accounting characteristics, which can be determined only after a long period of observation. This factor includes definite knowledge of "the capacity of a machine under known conditions, the degree of dependability for uninterrupted operation, the maintenance cost in repair parts and repair labor, the oil and power consumption per ton and the rate of depreciation." In this connection Mr. Johnson's paper briefed a statement by James Elwood Jones, general manager of the Pocahontas Fuel Co., which this year will produce by machine loading more than 1,500,000 tons of coal, that he can foretell a month or a year in advance, what tonnage can be produced at almost exactly what cost at any of his mines, some of which are being operated exclusively with loading machines.

He brought out the point that the loading machine is not so much needed as the engineering viewpoint in approaching the solution of physical and economic problems confronting the mine owner. He characterized the room-and-pillar system of mining as traditional, institutional, "from which any deviation is frowned upon by older heads." Departures from the old methods involve new problems which must be solved. Loading machines have stirred up revolutionary practice so that today operators everywhere are improving their haulage and tipples, experimenting with new shooting methods, studying roof action and developing long faces, hoping to obtain more efficient operation through the use of mechanical loaders.

## Banquet Program Includes Movies and Music

The outstanding feature of the banquet was the story of the "Exploration of the Grand Canyon," delivered by Col. C. H. Birdseye, of the U. S. Geological Survey. It was accompanied by photographic slides and moving pictures of the explorers' boats shooting the rapids and of the topographers making their observations, the purpose of the survey and level, which was carried through the canyon, being to ascertain where sites for dams could be established advantageously. To this end explorations were made of canyons entering on both banks of the river to a level such as would be invaded by the water if the proposed dams were erected. One of the proposed dams will, if erected, be 566 ft. high, and the water behind one dam will back up in every instance to the bottom of the next above it.

Jesse K. Johnson, president, Ridgeview Coal Co., Boliver, Pa., addressed the institute on the problems of the coal industry. He declared the operators were each engaged in seeking his own individual industrial advantage and viewed each question as a personal matter and not as one affecting the group. If they followed a principle of group action like the mine workers, they would gain for all what they could not obtain if each worked for himself.

Mr. Johnson said that not only had the miners in Illinois and Indiana penalized the operators by making a rate of $12 per day for the loading machine operatives, but they had added to the handicap by producing only

125 tons per day per machine. The non-union mines in West Virginia paid $5.67 per day and the machinery produced 300 tons daily. Yet the conditions in both regions were essentially the same. The "cost of operating the mechanical loader in union Illinois is 33.5c. per ton as against 7.08c. per ton in non-union West Virginia."

Mr. Johnson declared that the representatives of the U. S. Geological Survey had ascertained that at one large union mine where a careful check system is kept the miner only worked 27 per cent of the time. But this wage difficulty is not all. Mr. Johnson cited the freight-rate problems, saying that "The Pennsylvania R.R. has a rate to tide of $2.50 per net ton for an average of 227 miles and a rate from central Pennsylvania to East St. Louis of $3.82 for a haul of 700 miles. Anybody in a kindergarten would see that these rates are not equitable."

To the speaker it seemed that mergers were the only solution for the difficulties surrounding the operation of coal mines. "The operator," said he, "who thinks that overproduction will adjust itself is living in a fool's paradise and is due for a fool's awakening." Mr. Johnson called attention to the fact that a freight locomotive that in 1915 used 160 lb. of coal would do the same work in 1925 with only 55 lb., "L. F. Loree, president of the Delaware & Hudson Ry.," he stated, "said recently that in the present year $200,000,000 may be saved in the operation of the trains of this country, and that the 90,000,000 tons of coal now used in freight service can be reduced to 27,000,000 tons." "Cars," added Mr. Johnson, "driven with engines of the Diesel type running between Ottawa and Montreal on the Canadian National Rys., consumed fuel of the value of $5.87, while coal for an equal trip would have cost $35 or more.

William C. Hood, the incoming president, made a short address and excellent music was furnished by the Johnstown Glee Club, which is composed of members of the Safety and Welfare Association of the Bethlehem Mines Corporation. The Club was represented by 22 male members and two lady pianists. They consisted wholly of employees of the Bethlehem company's mines at Johnstown, which company provides for their entertainment and transportation. Dressed in tuxedos the club made an "immense hit" with the audience, their technical talent being remarkable.

---

# Pillar Recovery and Underground Substations

In the expectation that some of the mines that have been operated at a low rate of extraction might avail themselves of means by which their abandoned coal may be recovered, Dr. J. J. Rutledge described the work of recovering pillars at the former Detmold, Savage and Jackson mines in Lonaconing, Md. These mines are some of the real old operations of the bituminous fields. Detmold, for instance, was opened in 1853 and Savage in 1861. The three mines have caved extensively but now are being worked, Detmold and Savage by the Maryland Coal Co., and Jackson by the Georges Creek Coal Co. The first concern is using less timber than the second but is failing to recover the bottom coal and roof coal in the rooms. This coal is being retrieved, however, in the mines of the Georges Creek Coal Co. There the old workings are completely opened up and the material that has fallen is cast over into the gob except what is clean coal, that material being loaded out into mine cars for the market.

Mr. Rutledge declared that in areas where the original operating concerns had removed only 5,000 tons per acre, the Maryland Coal Co. was now loading out a further 10,000 tons per acre, for there is as much breast coal in the pillars as there was in the rooms and there is also bottom coal and top coal in those pillars 3 ft. of the one and from 2 to 3 ft. of the other, and, moreover, both bottom and top coal are retrieved from old rooms as they drive their new entries and as they crosscut from their new rooms to standing pillars. The methods of working were described in *Coal Age*, June 20, 1925.

Dr. Rutledge explained that the Maryland law and that of Kentucky provided that juries could be taken on the ground to view the damage made by mining and that in consequence the awards were tempered in those states with better judgment than in Indiana and Illinois. It would be well if those mid-west states had such laws. It might be possible then to remove the greater part of the coal.

The mines in Maryland where the recovery of coal is going on have such a high degree of concentration, especially as they are worked double shift, that an inspector can make a thorough investigation of such a mine in four hours whereas a similar examination of the thin Tyson-bed Mines above would take days, even though their outputs are no larger.

Elkins Read, of the Maryland Coal Co., in discussion said that in opening up the old rooms every alternate pillar might be skipped. If that were done it would be necessary to cross only one room when driving forepoling work through to recover the pillars. However, the skipping of every alternate pillar was found to weaken the roof so it was necessary to make the skipping only in one pillar of every three. In consequence two rooms have to be crossed by forepoling.

The cover being about 500 ft., the pressure is considerable. Mr. Read said that the miners, including those who were doing the forepoling work, averaged six tons per man. So far 350,000 tons had been removed by these methods without a single fatal or serious accident, though the work was dangerous. The men knowing the danger used due precautions, and consequently the excellent safety record detailed was attained despite the natural difficulties.

It was resolved after discussion that the Coal Mining Institute of America should become sponsor for George H. Ashley's coal classification, presenting it to the Mine Standards Correlating Committee for admission to the standards of the American Engineering Standards Committee. The standards were submitted to the Institute two years ago and were then studied by a committee which reported back to the Institute, giving them their approval.

C. H. Matthews read a paper on "Modern Practice in Underground Substations," saying that it was preferable to put substations underground where such stations were placed for the purpose of providing power at the working face. It was better to run the alternating-current cable down the borehole than to convert the current on the surface to direct current and put a direct-current feeder down the borehole.

He suggested that "permanent pumprooms generally make good locations for underground substations, as there is an attendant available and as the alternating current power for the pump motors and for the converting equipment can be transmitted over the same cables from the surface. Recent application of complete automatic operation of centrifugal pumps may, in time, eliminate the pumproom attendant, but automatic control can, of course, also be used on the substation equipment. Even if an attendant were present the use of automatic reclosing circuit breakers on the direct-current feeders is recommended. Their use eliminates delays in operating the circuit breakers and prevents a careless attendant successively reclosing breakers on short circuits, thus injuring the machines.

"Where hoists are located underground it is sometimes possible to locate the converting equipment in the hoist room. In this case reclosing direct-current circuit breakers are a necessity as the hoist operator must give close attention to his hoist and cannot stop a trip to reclose circuit breakers. On the other hand, production cannot be held up waiting for circuit breakers to be closed."

In response to this statement Graham Bright remarked that the attendant on a substation had the easiest job around a mining plant. Mr. Bright regarded it as desirable that the station runner should have other duties than operating the converting equipment, enough at least to keep him from falling asleep. As the result of his freedom from toil he often neglected his few but important duties and, therefore, it was well not only to put an automatic reclosing circuit breaker on the line but to protect the alternating-current motor automatically against phase failure and the bearings against excessive heating.

Question No. 4, relative to arcing of electricity between steel rails and steel ties and the possibility of thereby starting a mine fire, was presented anew by M. D. Cooper, in reopening the question box. G. S. Rice said that he believed imperfect bonding was the cause of many mine fires even with wood ties. He had noticed evidences of such danger. Consequently the problem was solely: Did steel ties accentuate that risk? The menace was present in some degree no matter what kind of tie was used.

The next question, "What items should be entered on a coal company's cost sheet?" and "What constitutes what is known as strictly operating cost?" revealed that the standards of accounting prepared at great expense and much labor by the National Coal Association are not getting the observance their value and authority demand.

A. K. Pollock, of the Ford Collieries Co., said that as an operating man he naturally sought to have as little as possible charged to operating cost. F. B. Dunbar, general superintendent, Hillman Coal & Coke Co., wanted the most careful and day-to-day operating costs and the most general knowledge of those costs among the men in charge at his mines. Only when they were so provided and understood would the mine officials interest themselves in economical operation. J. K. Johnston urged that accurate operating costs be kept so that no one could fool himself that he was cutting costs when all he was doing was hiding his eyes to economic loss. Mr. Rice said that classifications and arrangements of costs were too often such that it was impossible to find out what costs were chargeable to mining, what to haulage, what to ventilation and what to drainage.

### SINGLE ENTRY IMPERMISSIBLE

Mr. Dunbar, in replying to Question No. 6, as to the best method of ventilating single-entry work especially where new methods of mining are being tried out, said there was no proper method of driving single entry for single-entry development was itself impermissible. H. I. Smith wanted permissible motors and a permissible switch where auxiliary fans were in use, but Mr. Rice declared that if these fans were stopped there would be gas pockets and that if kept running 24 hr. per day it would be necessary to have continuous attendance, otherwise they might stop or a fall might cause an untoward accident.

Mr. Rice said that foreign practice in regard to boosters had been misrepresented. Booster fans were used, it is true, in foreign mines. Where the extension of the workings was considerable and leakage great and irreducible, the water gage used, though high, might be unable to cause the air to circulate in sufficient volume, where a single fan was employed. In consequence boosters might be used to meet this condi-

**Ralph Beerbower** **A. K. Pollack** **A. E. Holbrook**

Were among the members of the Coal Mining Institute of America at the annual meeting in Pittsburgh. Mr. Beerbower, of Pittsburgh, and Mr. Holbrook, of State College, Pa., retired as managing directors of the Institute. Mr. Pollock is general manager of the Ford Collieries Co., Curtisville, Pa.

tion, one unusual in this country. This need is particularly pressing in the mines which, being driven far away under the sea, cannot shorten the length of their aircourses by auxiliary shafts.

In Germany and France tunnels driven across the strata are, it is true, ventilated during construction by auxiliary fans and air ducts, but these fans are driven by compressed air and no development is attempted till these tunnels have reached workings so as to permit the ventilation to be established by the action of the main fan. H. N. Eavenson declared he had given the matter no thought, but he didn't like single-entry methods at all and E. H. Coxe was about equally unfavorable.

# What Shall We Do About Mine Timber?

The Thursday afternoon session opened with a paper by H. S. Newins, Department of Wood Utilization, State College, Pa., on "Our Mine Timber Supply in Pennsylvania and in Other Coal Producing States." This will appear in a later issue of *Coal Age*. He mentioned the fact that where the moisture content of the wood is kept below about 20 per cent rot is largely eliminated; but this condition would require a low relative humidity. Inspector Girod for obvious reasons would avoid the establishing of this condition as a means of preserving mine timbers and stated that mine owners must adopt some other expedient or else suffer the loss caused by rot. In his paper Mr. Newins suggested for secondary preservation and for protection the use of plastered or projected concrete on creosoted timber lining in downcast shafts. Graham Bright wanted to know whether projected concrete alone would serve the purpose and was told that the timbers must first be immersed in or brushed with a preservative solution if rot is to be avoided.

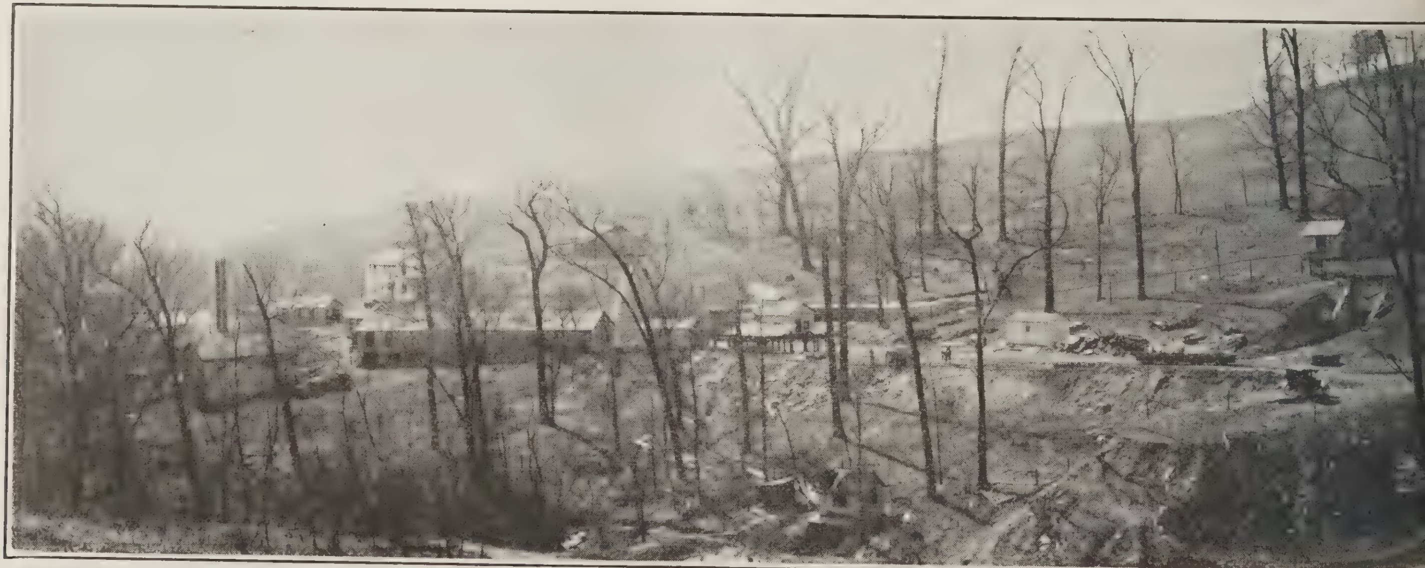
Mr. Newins explained that dry rot is contagious; that the practice of scraping from wood exterior growths of fungi is not beneficial and may serve to spread the disease to nearby healthy timbers. Dry-rot fungi are not necessarily developed by a low relative humidity nor by a high. Good ventilation checks their growth. J. T. Ryan asked if limestone dust has any tendency toward preserving timbers. He was informed that it has none. Patrick S. King, mine inspector, wonders why conifers are so widely chosen by coal companies in the reforestation of denuded or partly stripped timber lands. The answer is that conifers are most easily handled and transplanted because of their shallow rooting as against the hard woods which are hardest to handle.

Mine Inspector Ira Thomas, of Johnstown, Pa., sought an explanation of the methods of creosoting timbers. One way is by brushing; another by immersion in a bath of creosote which is alternately heated and cooled until the desired penetration is obtained. J. J. Forbes, of the Bureau, desired to know what degree of penetration is needed and was told that penetration must be deeper than injuries by abrasion. Brushing is quite satisfactory on timbers not exposed to abrasion.

The next paper on "What Some Coal Companies Are Doing to Replenish the Mine Timber Supply" was read by Graham Bright in the absence of the author, Newell G. Alford. This paper also will appear in an early issue of *Coal Age*. The paper indicated what might be expected as the normal growth in the consumption of timbers by coal mines in the future. Mr. Rice expressed a thought that concrete and other substitutes, might lower the consumption of timber by mines because of the increasing cost of the latter. Mr. Bright looks for no such effect in the next ten years at least.

Because of its rapid growth, would not the catalpa tree be well suited for reforestation, wondered Nicholas Evans. Mr. Newins answered this question. Quick growth is not a factor inasmuch as properly developed reforestation programs involving trees of stronger wood structure will meet and exceed normal demands upon them. Mr. Rice was told in answer to a question in this regard that the catalpa is about as susceptable as and less desirable than many other trees.

At this point R. M. (Bob) Lambie, chief of the West



**Bruceton Experimental Station, Near Pittsburgh, of the U. S. Bureau of Mines.**

On the last day of the Institute's meeting the men went to this station where various demonstrations of rescue and safety equipment were given, and where a coal dust explosion was put on. At the right is seen the steel testing gallery. In this gallery

Virginia Department of Mines, was asked to make a few remarks. He is not bothering about, nor is he elated by, high production in his state which is now leading all others. He has an eye more for safety and was happy in being able to announce that his force has been increased by three men. His department is doing things in the interest of safety. The Bureau of Mines has loaned him the services of W. H. Forbes of Huntington, W. Va., who is now engaged co-operatively in a study of roof conditions in West Virginia mines, toward the end of uncovering wider knowledge of roof control which will be passed on to the operators.

A question box discussion then ensued, led by Mr. Fear. The lead-off to this part of the program was a paper by J. E. Tiffany, Bureau of Mines, covering methods of producing more and better lump coal, in which he gave several methods of shooting under various conditions. One mine in Illinois producing 4,000 tons of coal a day has been able by a standard system of shooting alone to increase by 2 per cent its yield of 6-in. lump. It is possible to get straight ribs with top cutting but not always uniformity of depth of the cut. Rib holes always should be placed parallel to the rib at a point from 1 to 3 ft. from the latter.

Exception was taken by Mr. Fear to one of Mr. Tiffany's statements regarding the degree of increase of lump coal by the use of rock dust stemming. This practice when properly followed will yield a good deal more than a 5.4 per cent increase in lump coal. The rock dust should be deposited lightly in dummy cartridges which should have a 1¼-in. diameter for a 1½-in. hole, and the ends should be more or less open. Mr. Maize wanted to know whether more lump coal can be produced by tight tamping of rock dust stemming. Mr. Fear said "yes" but Mr. Tiffany said "no." The latter has been able to increase the lump by 5 per cent by this means. Tests show that tightly tamped rock dust can be compressed to at least one-half its original volume by heavy hydraulic pressures.

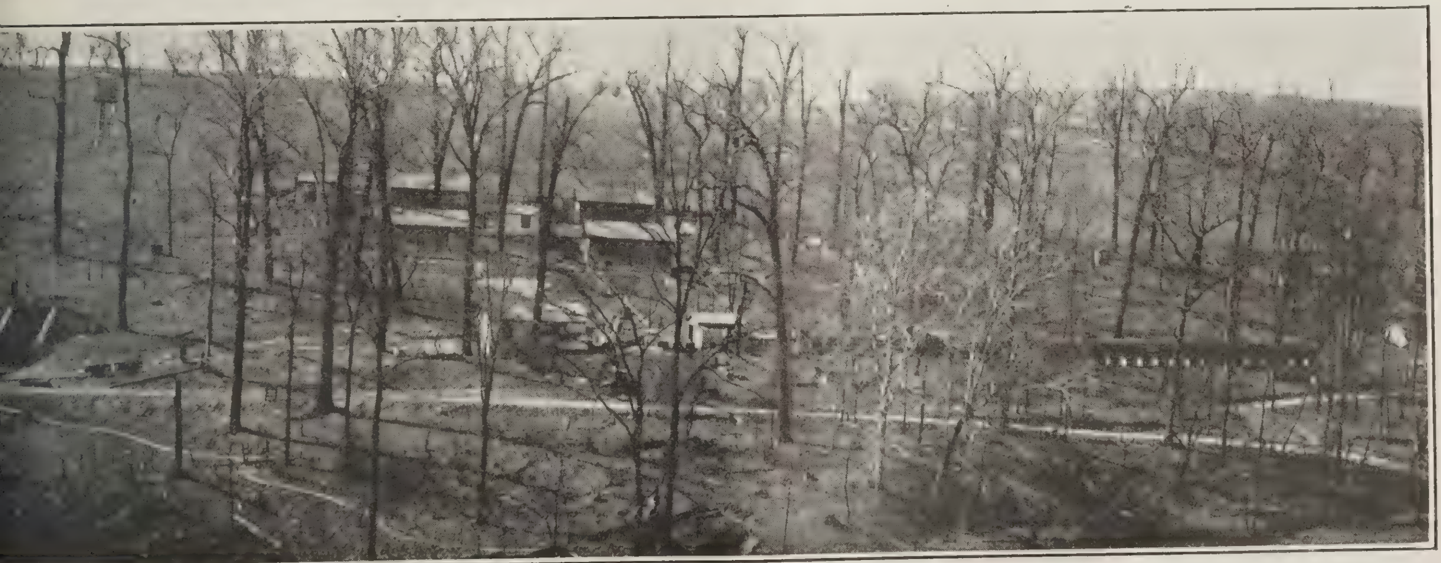
C. W. Nelson, explosives engineer, Hillman Coal & Coke Co., has found certain plants increasing the production of lump by reducing the diameter of the cartridge and lessening the weight. The length of the charge is an important consideration. At one mine the diameter of the cartridge was reduced from 1½ to 1¼ and then to 1⅛ in. with increasingly better results and at a saving in powder cost. Companies should find out how small a diameter can be used and what is the deterioration in the explosive of a cartridge of the minimum diameter. Supervision in shooting is of little benefit without standard and uniform powder.

E. H. Johnson believes as good results can be obtained with permissible explosives and rock dust stemming as can be obtained in the same way with black powder, providing the charges are scattered. B. L. Lubelsky, explosives engineer of Washington Gas Coal Co., and former research man of the Bureau of Mines, discouraged the propensity toward the use of black powder as a producer of more lump coal. His research tests show that a high-rate permissible gives the best results. In a loose coal the gases arising from a slow powder escape along the bedding planes. Slow powder is all right in hard coal but in soft coal he encourages the use of a fast powder.

### BLASTING COAL FOR LOADERS

Here the discussion turned to a specific question: "What is the best practice for the blasting of coal for mechanical loaders and do the latter have any decided effect on lump coal?" To get best results in shooting coal for mechanical loading he would use four or five shots instead of two or three, without increasing the total quantity of powder. Snubbing shots are quite beneficial. Mr. Nelson asked if it would be practicable to shoot and load mecahnically a cut in two steps. That procedure would further reduce the now comparatively low running time of the loading machine. H. H. Hamilton called attention to the fact that the deeper cuts which mechanical loading is generally commanding will require radical changes in methods of shooting.

Mr. Johnson stated that unduly hard shooting and not the loading machine causes pronounced degradation of coal in mechanical mining. A comparison of results attained in two mines by a company in the Pocahontas field—one producing 50 per cent of its output with loading machines and the other its entire output by hand loading—showed that the former loaded 17 per cent less slack than the latter



**It was Visited by the Coal Mining Institute of America Last Week**

miniature explosions of gas, coal dust or both are staged. In it developed pressures, temperatures, etc., are carefully recorded and the manifestations studied. Some of the explosion tests the Institute saw were terrifying to novices.

The eighth question was "Is scientific management applicable to the coal mining industry and can anything be learned from manufacturers?" Mr. Fear regards mine supervision wholly inadequate as compared, for instance, with outside gang labor where in spite of the fact that the men work together in large groups, and in plain sight of the overseers, a larger number of the latter for a given number of workmen are provided than in the coal mines. Of recent years, however, supervision has improved. He prefers the name "section foreman" to "assistant foremen" and does not extend the authority of any beyond the limits of a section.

J. K. Johnson, Bolivar, Pa., believes there are wide possibilities in scientific management especially in laying definite construction plans in advance. One company asked a superintedent to lay out and estimate the cost of a five-year construction program for his mine. This was passed on by the engineering department and then reconsidered by an outside party after which it was presented to the board of directors. The latter approved the program and appropriated the necessary funds without argument, chiefly because the program was carefully planned.

Mr. Fieldner believes the industry can learn much from other industries and by research. He pointed to the accomplishments of the co-operative research fellowships between the Carnegie Institute of Technology and the Bureau of Mines which are being supported by industries, as convincing evidence. Mr. Hall said that the manufacturer does not leave design to workmen. In the factory everyone knows what to do and how but in the mines there are no standards and, consequently, jobs are done in a hundred different ways apparently without knowledge of the best. Mr. Fear thinks every operation should have a good mechanical man as well as a mining engineer and a chief electrician.

### Must Consider All Problems

M. D. Cooper, assistant general superintendent of the Hillman Coal & Coke Co., believes the widest avenue leading to improvement lies in the rerouting of coal as it lies in the rerouting of materials in the factory. There is danger of concentrating too much on one aspect of the problem, as, for instance, the mechanical loading of coal, and forgetting other interconnected problems.

Mr. Rice let it be known that the industry owes much to the manufacturer, who has supplied much of the mechanical brains. Sometimes, however, the manufacturer forces the mine owner to fit his conditions to a machine instead of vice versa. Capt. Steidle deplored the fact that few mine owners really know what is being done, nor how long it takes to do a job or what it costs. This fact was brought home to him during his investigations on behalf of the Coal Commission. The Lynch mines of the U. S. Coal & Coke Co. in Kentucky have, and continually compile, data of this sort which are weighted and averaged as standards. These are the tools of the officials.

The last question of the day, "Is it safe practice to use open lights in so-called non-gassy coal mines?" unloosened some pointed remarks. Frank Dunbar, of the Hillman Coal & Coke Co., knows of no non-gassy mines. One can't be too careful, he warned, and the open light is a danger in itself in home, factory or mine.

**D. R. Blower**

A member of the Institute from California, Pa., who served as a managing director during the past year.

Mr. Thomas said that while the state mining law allows open lights in some mines he condemns the practice even though in a number of old mines, as in those of the Broad Top field and surrounding regions of Pennsylvania, no gas has been detected by ordinary means in 60 or 70 years.

Mr. Hall insists that laws governing other practices must follow immediately after exclusive use of electric cap lamps in our mines, as compulsory use of permissible equipment and flame safety lamps everywhere. Otherwise, he believed men would carry matches and resort to other unsafe practices. Mr. Rice said that too much reliance should not be placed in ventilation as a means of keeping mines clear of accumulations of gas. Men not of that belief have had disastrous explosions. He seconded Mr. Hall to the extent of expressing a view that flame safety lamps should be installed for inspection purposes in conjunction with electric cap lamps. The flame safety lamps should be magnetically locked.

Mr. Bright said the rock dusting committee showed no discrimination in its recommendations as between so-called non-gassy mines and gassy mines. He believes this would be a good suggestion to apply to the case of electric lamps vs. closed lamps. As the flame safety lamp will not detect methane in quantities much less than 1 per cent many men feel safe in this regard but the chemist always finds it. Mr. Fear said it costs the mine owner nothing to install electric cap lamps.

The program closed with the reading of the following resolution:

Whereas, the U. S. Bureau of Mines has established stationary and traveling centers of instruction in safety, mine rescue, first aid and mine recovery; has given valuable aid to the industry in making mines safe; has assisted helpfully in mine rescue work, and has accumulated stores of information relative to safe conduct of mines, be it

Resolved, that the Coal Mining Institute of America emphasize to the new director of the U. S. Bureau of Mines, Mr. Scott Turner, Mr. Hoover and others the importance of this work, which has proved so helpful to the industry, and urges that this work shall in no way be restricted on account of other activities.

## Institute Sees Explosions in Bruceton Experimental Mine

ONE OF THE TESTS being made as a part of the regular investigations of the U. S. Bureau of Mines was staged on Friday morning, Dec. 11, for the edification of the members of the Coal Mining Institute of America, most of whom journeyed in automobiles to the experimental mine at Bruceton, Pa., where the tests were made.

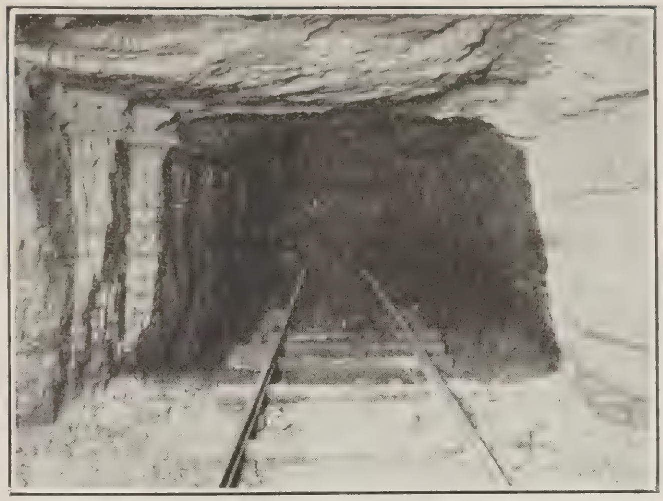
In the end of the right-hand main entry a large number of gas jets had been installed on the floor, and arrangements were made to shut in these jets behind a paper diaphragm located at a point 50 ft. from the face. The cross-section of the entry measures 6x10 ft. approximately, so it is estimated that back of the diaphragm was about 3,000 cu.ft. of air. Enough gas was released to bring the gas content up to 10 per cent. The gas used was the natural gas which is conveyed to Bruceton by pipes.

In front of the diaphragm were shelves which extended 475 ft. outby and were covered with a mixture of 65 per cent shale dust and 35 per cent subbituminous coal from Hanna, Wyo., both reduced to powder of standard fineness. Similar charges of a like mixture of Hanna coal dust and shale dust were placed in the crosscut near the diaphragm and in the heading parallel to the right-hand entry which also comes to the surface.

The dust-charged shelving in this case extended to a point 25 ft. further from the surface than the shelving in the right-hand main entry. The gas behind the diaphragm was set on fire by a black powder igniter. When the gas was exploded the crowd alongside the portals was immensely impressed by the terrific rush of wind laden with dust which swept out of the mine and licked up everything in its path. Some of the visitors who were located alongside the right-hand main entry, which was the one in which the gas was released, declare that they saw flame in the whirlwind and the Bureau of Mines officials announced later that evidence of the passage of flame beyond the dust-charged shelving was obtained by observations made in the instrument station on the hill.

At the close of the explosion four men wearing four different types of oxygen-breathing apparatus and four men wearing all-service gas masks entered the mine to take samples. Later these samples were tested with the Orsat apparatus and no carbon monoxide was found, but it was stated that the Orsat apparatus gives unsatisfactory indications of this gas, and being correct within one- or two-tenths per cent. Such a concentration would be sufficient to paralyze a man in an hour or so. However, the canary and the hoolamite indicator both showed that carbon monoxide, if present, was in low concentrations.

Rock Dusted Entry in Experimental Mine



Where Rock Dust Zone Ends in Experimental Mine

Prior to this important test the Bureau of Mines arranged to precipitate 30 lb. of Pittsburgh-bed coal dust in the main entry of the mine near the portal in such a manner that it would be carried by the outgoing air to an electric arc and later, in another experiment, to an open flame. In each case there was a general and sudden inflammation which extended to the surface. Some stationed themselves inside the mine behind the curtain of coal dust, and the view they obtained of the rapid combustion was one never to be forgotten. The flame filled the whole cross-section of the entry. There was, however, no violence.

Rock-dust barriers of proved ability to stop mine explosions were exhibited on the surface and tripped by the pulling of wires or the operation of vanes. Later, a steel tube, 12 in. in diameter and over 100 ft. long was filled with natural gas and air, the gas concentration being 7 per cent. Flame was applied at one end and in a slow, quiet way it propagated the full length of the tube, the Institute members in stooping posture watching its progress. When the flame reached the far end of the tube, the gas exploded much to the surprise and consternation of the visitors who were not in any position to make a quick run to safety should such a run be necessary. When an inflammation starts at the open end of a gallery it travels slowly and builds up but little pressure. When it starts at the closed end of a pipe, entry or chamber, however, as did the big explosion in the mine, which was staged later and has been already described, the effect is far more violent.

Demonstration in a glass gallery of the explosion of coal dust by an open light followed after lunch. A shot of permissible was then made into a gallery designed and erected for the testing of permissibles and another also against a ballistic cannon which measured the force the explosion generated. Finally a shot of black powder in the gallery with 50 lb. of coal dust present brought the usual violent explosion with flame spouting from the end of the gallery and from the many port holes. A brilliant exhibition was the explosion of a steel keg of black powder by contact with a charged electric wire. Later a trip was made through the experimental mine to see what the results were.

# Coal Problems Get Much Attention at Washington Convention of American Mining Congress

**By E. W. Davidson**
Managing Editor of *Coal Age*
New York City

LEGISLATIVE and economic coal problems of the day absorbed a good deal of the time of the twenty-eighth annual convention of the American Mining Congress at Washington, D. C., Dec. 9, 10 and 11. Attendance, never large at this mid-winter "policy meeting," was not easy to maintain at all the sessions, but those devoted to coal held much of interest to the whole industry.

The convention gave Secretary Herbert Hoover of the Department of Commerce opportunity in a banquet address to impress his hearers with his desire to make the government a friend rather than a suspicious guard of mining industries and provided a propitious moment for him to infer his opposition to radical coal legislation by declaring, "You can't catch an economic law with a policeman."

It gave Secretary of Labor James J. Davis a chance to propose that the coal industry try curing some of its own ills by creating a fact finding commission of its own to regulate the industry from the *inside.* He suggested a coal dictator of the Will H. Hays variety and took a rap at railroads for contributing deeply to the grief of coal by buying fuel off their own lines and at less-than-cost prices.

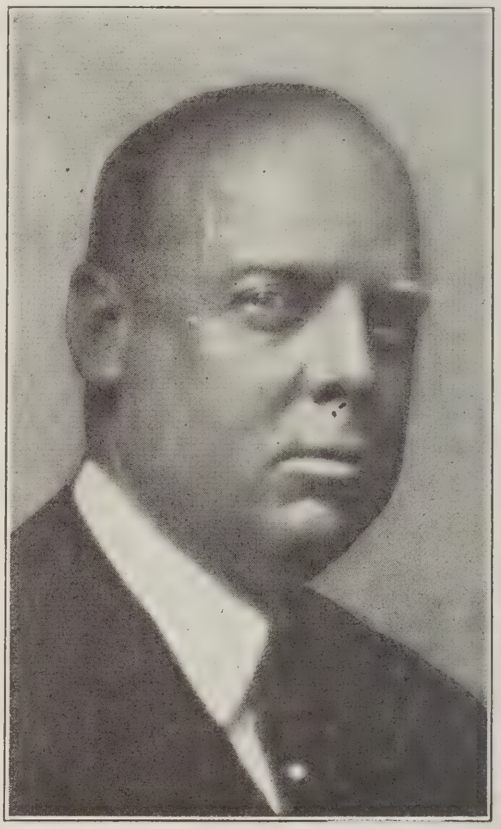
There was opportunity also for Samuel D. Warriner, chairman of the Anthracite Operators' Conference, to make a strong re-setup of the anthracite operators' case and for several other coal men to speak some truths about coal.

The meeting elected D. B. Wentz, a well-known coal operator, president of the congress for the forthcoming year, the manufacturers' division began its plans for a great coal show and technical convention next May, the standardization work of the congress moved forward a notch, government and business was discussed and nearly every man in attendance visited the White House to receive President Calvin Coolidge's how-do-hurry-along handshake. However, it was a leisurely convention.

"I am surprised that the expression 'too many miners' recurs so often in present-day discussions of what ails the coal industry," said Josiah Keeley, president of the Cabin Creek Consolidated Coal Co., the first of several speakers who reported on mining conditions in various parts of the country at the opening session Wednesday under the chairmanship of vice-president Wentz. "The real trouble is only 'too many mines.' Why, in West Virginia today I don't know a single mine that has enough men."

He appealed for some remedy for overdevelopment—probably greater consolidations—adding that he did not believe West Virginia non-union operators were fooling themselves into thinking the present labor condition there would continue indefinitely. Even though some of the men working non-union there right now are making more than they have made since 1915, still they have been fooled so often by union leaders and operators alike in past years that now they have none too much confidence in either.

Duncan Kennedy, secretary of the Kanawha Coal Operators' Association, was inclined to discount Mr. Keeley's thought that non-unionism is unstable in West Virginia. He agrees, however, that "the labor policy of the state is charged with dynamite." He thinks the union will never again rise in Kanawha, the arrogance of local and district leaders having killed it. The few union camps in the region are maintained, he said, by the United Mine Workers' payroll. The men in the mines generally are satisfied with the treatment operators give them and are working loyally.



**Col. D. B. Wentz**

Elected president of the American Mining Congress for the coming year. He served as vice-president of the congress during the past year. Colonel Wentz is head of the Stonega Coal & Coke Co. and associated interests.

The venture in 1917 wages within union territory now being made by the Pittsburgh Coal Co., the Rochester & Pittsburgh Coal Co. and the Buffalo & Susquehanna Coal & Coke Co. was mentioned by Mr. Wentz in introducing A. P. Cameron, vice-president and general manager of the Westmoreland Coal Co., long a non-union company. Mr. Cameron said his organization had spent "a mint of money" in 1910 to show union men that they could not run the company's property and that if all operators would do that, and then treat men right, the great labor difficulties handicapping the industry would be removed.

"There's a long hard fight ahead of the Pittsburgh Coal Co.," he said, "but I believe the company means business and will stick to its less-than-Jacksonville-wages program. The situation in western Pennsylvania is a little dark just now but is quite satisfactory for all that."

President Coolidge, unable to attend, sent greetings to the Congress in a letter in which he hinted at no government control or operation of anything, but said rather that "the eventual solution of the large problems of industry will be solved through the earnest, united and unselfish labors of men comprising such organizations as yours. So far as lies within its power the executive arm of the government is ready and willing to lend its aid in this work."

The Wednesday afternoon session was given over to a discussion of mine taxation but no emphasis was put upon coal tax problems. Paul Armitage, chairman of the general tax committee of the congress, presided. The speakers were Joe J. Manlove, congressman from a Missouri district, and George R. Holmes, of New York.

### "Strike Creates No Crisis"

Although Secretary Herbert Hoover was the principal speaker at the Wednesday evening banquet, Harry N. Taylor, head of the United States Distributing Corporation of New York won the most space in the next morning's newspapers by declaring that "there is no crisis created by the anthracite strike." He said 90 per cent of the people already burn soft coal and the rest can get used to it soon. Anthracite producers are losing some domestic business permanently, he declared, but their principal loss in this strike is steam business which covers 50 per cent of the anthracite produced. This they may never recover.

If the strike is not settled by Jan. 1 it might as well run until next summer so far as the people of the country are concerned, said Mr. Taylor. He hopes nothing will interfere with the anthracite operators carrying the fight to a finish for a settlement that is final and right.

Senator Oddie, chairman of the Senate committee on mines and mining and who has some coal men disturbed by his new coal bill, paid tribute to Secretary Hoover as the most favorably known engineer in all the world. Because the Bureau of Mines is now under Mr. Hoover's direction, he prophesied greater co-operation between the department and Congress on mining legislation than Washington has ever seen.

"No man with a double chin ever leads a double life," neatly epigrammed former Senator C. S. Thomas of Colorado, the nimble-witted banquet toastmaster, as he introduced Secretary Hoover. He was not defending the eminent Secretary's morals, which do not need defence, but was merely explaining why Mr. Hoover, being only one man and with but twenty-four hours a day at his disposal, has not accomplished everything everybody expects of him.

Mr. Hoover, in guarded phrases treated only indefinitely the big problem of possible legislation looking toward outside interference in the mining industries of the land. He did make it plain, however, that he favors no legislative efforts calculated to guide economic law in its operation upon industry. "You can't catch an economic law with a policeman," said he, and his attentive audience put its own obvious interpretation upon his words.

He pointed out that the mining industry is "older than the tablets handed down on the Mount" and that in all the ages it has conformed to the immutable economic laws which still delimit its functioning. Therefore, there is no need now for government correction. He holds that government can serve the mining industry technically but not by economic meddling "unless the ten commandments can be changed." However, he urged the members of the Congress to "keep up your interest in legislation. We are going to need you all."

The organic law creating the Department of Commerce provides, he said, that the Secretary shall "promote and foster" industry. This puzzles him, for anybody in Washington who sets out to "foster" any industry is under grave suspicion to say the least. But he does understand the soundness of promoting industry and that end will be served, he thinks, by the recent transfer of the Bureau of Mines from the Department of the Interior to his own department. An economic division, widening the service of the department to industry, will be created as from Dec. 15, he announced.

Mr. Hoover took occasion to pay high tribute to the type of men that have been in the service of the Bureau of Mines in the past, most of whom have made heavy financial sacrifices to remain in government employ. He expressed regret at the departure of Director H. Foster Bain but assured the Mining Congress that in Scott Turner the Bureau leadership will be of the ablest. Mr. Turner, he said, is giving up business connections that pay him five times the salary he will receive from the government.

The big coal session of the convention was that of Thursday morning when James J. Davis, Secretary of Labor, proposed an internal fact finding coal commission and declared railroads could correct many coal ills by better buying. James Murdock, former Minister of Labor in Canada, described the operation of the compulsory arbitration law of Canada, and S. D. Warriner, chairman of the Anthracite Operators' Conference, made a clear-cut statement of the operators' position in the present strike printed on another page of this issue.

Secretary Davis, approaching his proposals for the correction of coal's troubles "from within," said that great as is the necessity for curing labor troubles the greater need is to cure other economic disturbances inside the industry. Although in 23 years, from 1900 to 1922, a total of 207,000,000 man-days were lost in strikes in the American coal industry that accounts for but 14 per cent of all lost time. No markets, car shortage and mine disability roll up the far greater total.

### Industry Must Protect Itself

The problems of intermittency of operation, irregular employment, unprofitable production for owners and unsatisfactory wages for miners caused by "too many mines and too many miners," must be solved. He knows of no legal restriction that can be put upon overdevelopment or overmanning of the industry. Therefore, he thinks the industry itself must prevent them.

"It would appear," said he, "that within the industry real progress might follow the adoption of a scientifically developed plan for voluntary reduction in the number of high-cost mines, limitation of the new mines to be opened, an arrangement for absorbing into other industries the surplus mining labor, and a policy of discouraging the employment of casual mine workers in the busy seasons by confining such work to the steady employees of going concerns.

"For this very difficult undertaking I believe that a fact finding commission should be established within the industry itself to be composed of equal representation of miners and operators with a disinterested chairman. Such a commission, composed of leading minds from operators and workers, and animated by a spirit of co-operation and mutual trust, would be at once far more expert and better informed than any commission working from the outside. An inside body of this nature would possess a practical knowledge of every phase of the mining industry, from the mining to the marketing of coal, such as no other body of outside experts could hope to possess. If established by the industry itself, such an inside commission would instantly command the confidence of the public, as an expression of good faith on the part of the industry to begin with. I earnestly urge both operators and miners to consider seriously some such means—the only means available, as I see it—for overcoming the first evil of over-development.

"Among other factors necessary to stability of operation and employment I regard as important a broadening of railroad policy in the purchase of fuel. If each railroad bought its coal of mines along its own lines, and paid a price that would insure a reasonable profit, and bought at such season as to insure more regular operation, another great evil of the coal industry would disappear. As now, some railroads bargain for their coal on the lowest price offered, by mines often remote from their systems. The consequence is that operators on their own lines frequently furnish railroad fuel at a loss. The communities about these mines are impoverished, general freight and passenger business is curtailed by this custom of buying coal mined in fields away from their own roads and the railroad itself is thus the sufferer by its own fueling policy. It would seem to me good business for every road, where possible, to buy its coal from mines on its own lines and at a fair price to all concerned."

The Secretary of Labor declared for voluntary arbitration. Compulsory arbitration, however, having failed in Australia, Canada and in Kansas, is hopeless, he thinks.

As a final word to coal men, he urged them to choose a "national figure," a man skilled in law and business administration, to apply whatever corrective measures may be proposed by the suggested fact-finding commission.

Canadian compulsory arbitration is not the complete failure it is so often pictured. Mr. Murdock told the convention. The industrial disputes act prohibits strikes or lockouts before and during conciliation proceedings. Since 1907, he said, out of 638 applications for arbitration boards 450 have been granted and the remainder of the cases settled by the labor department. In only 38 cases did the machinery fail to prevent strikes or lockouts.

Some progress toward getting mining standards approved by the American Engineering Standards Committee was reported by Col. W. R. Roberts, chairman of the congress standardization division on Thursday afternoon. The congress report on mine ventilation was adopted that very day in New York by the A.E.S.C. and was said to have been sent out for a formal letter ballot.

However, there had been such difficulty getting the ventilation code adopted that Colonel Roberts was moved to charge the secretary of the A.E.S.C. with "irregularity" and violation of the rules of his own organization.

The Colonel said the ventilation report had been unanimously adopted by a section of the A.E.S.C. correlating committee and, therefore, should have received the formal approval of the correlating committee Nov. 11 in New York. It did not, however, and the correlating committee voted to send it back to the sectional committee for alteration on the ground that the Bureau of Mines, one of the original sponsors, had withdrawn its approval.

### Colonel Roberts Does Battle

It appears that one Bureau engineer, who represented the Bureau officially, had approved but that a superior objected. Colonel Roberts said that on Nov. 11 he notified the correlating committee that if it insisted upon referring the report back for change he would appeal to the whole American Engineering Standards Committee the next day. This he did and won a decision to mail the report out for a letter ballot.

He said, however, that the secretary did not mail it and that no action took place until the one in New York Dec. 10 which assured the adoption of the committee report as a tentative American standard.

Colonel Roberts reported that the congress' committee

American Mining Congress Assembled with President Coolidge reports on drainage and underground transportation are getting attention from the sectional reviewing committees of the A.E.S.C. and should soon be acted upon after more than two years of delay. This delay, he said, was largely unavoidable because of the A.E.S.C. geographical and industrial distribution of the A.E.S.C. committee personnel. However, future action ought to be swifter, he thinks. Three other reports of congress main committees are awaiting review by the A.E.S.C. —reports on outside coal handling equipment, power equipment and power transmission.

The remaining two main coal mining branch committees of the congress—those on mine timbering and on underground mining and loading machines—did not finish reports in 1924. However, several subcommittee reports on parts of the mine timbering committee's work were made at the convention. George M. Hunt read a progress report on timber preservation, B. C. Collier, former subcommittee chairman, read one on the use of "Concrete and Gunite for Underground Construction" and Newell G. Alford, the new chairman, read an important report on an investigation of "Concrete for Shaft Linings."

A final report on mine drainage embodying several previous progress reports was made during the convention as was a final report on mine tracks and signals by a subcommittee of the underground transportation committee.

During the standardization meetings an address was made by R. M. Hudson, chief of the division of simplified practice of the U. S. Department of Commerce, and a progress report by the standardization division for the metal mining branch of the congress prepared for the chairman, C. A. Mitke, was read by William A. Rowe, chief engineer, American Blower Co., Detroit, Mich.

The coal industry need no longer feel that it is going to be hounded under the anti-trust law, two speakers assured the convention at the Friday morning session. One was William E. Humphrey, of the Federal Trade Commission, who described the great change that has been made in the highly doubtful practices of that commission, and the other was Gilbert H. Montague, a New York lawyer, who urged the mining industry to obtain for itself at once the same exemption from the terms of the Sherman law that railroads, telephone companies, farmers and labor unions have long enjoyed.

Mr. Humphrey was wholehearted in his condemnation of past practices of the Federal Trade Commission. But he said two great changes in method have been in effect since last March which make the commission assist business instead of harassing it. In past years the commission, he said, has sent out investigators to work on every complaint and their reports have been made public without even hearing the respondent. In 50 per cent of these cases, after months and even years have elapsed, during which the publicity may have ruined the business under investigation, the charge has fallen flat. Now the commission uses no such public methods.

The other important change is the use of the "stipulation" system. When an investigator's report makes a prima facie case there is a hearing before a board of review. The case may be dismissed as unjustified. But if the complaint of unfair business practice proves justified the commission is willing to accept a signed stipulation from the respondent in which he agrees never to repeat the offence. Often he has broken the law without knowing it, a condition that should cause no surprise in view of the differences of Sherman law interpretation made by various agencies even including the Supreme Court itself. Only in flagrant cases of willful violation does the commission carry the matter to court.

This plan has been assailed by "the pink fringe" of both republican and democratic parties and by out-and-out radicals, but by no others, Mr. Humphrey said. It is a successful and just plan and usually produces the desired result, often in cases where it would be impossible to gather sufficient evidence to win a prosecution suit. It is square to business and it saves at least $500,000 a year to the government in court costs, he said. He declared the commission is now correcting an average of one case a day, whereas it formerly averaged only one a week. No longer, he said, will cases hang fire for years. They are handled expeditiously.

"The Federal Trade Commission now believes that business men in this country want to be honest," said Mr. Humphrey. "It no longer holds that business success and dishonesty are synonymous."

**on the White House Lawn, Washington, D. C., Wednesday, Dec. 10**

**Harry N. Taylor**

President of the United States Distributing Corp., who declared at the American Mining Congress meeting that "there is no crisis created by the anthracite strike."

Mr. Montague, following Mr. Humphrey, declared the change in the commission's methods has done more to bring order to American business than any other one thing since the passage of the Sherman act in 1890. Further, he said, there never has been a time in the last 35 years when business got such sympathetic decisions from courts and commissions as it is getting now. There is no longer any reason why coal operators should fear to deal collectively with their labor and that trade associations need not fear to function.

Mining is the greatest waster of all industries, he declared, largely because the units in it have not been able to function freely and legitimately under the various interpretations that have been put upon the anti-trust statutes. Now, however, sound consolidations of mining properties to reduce overhead and improve production are possible with impunity and trade associations can safely exchange information that will reduce the wastes of distribution.

Sidney J. Jennings, president of the American Smelting & Refining Co. of New York, after defining a "fair wage" as one that would permit a man to "feed, clothe and house himself and have enough leisure to recuperate his strength and increase his ability to earn" declared that experience has proved that "high wages coupled with high efficiency produces most profits" for both capital and labor.

Said he: "It is the manifest interest of society to see that no nationwide organization of workers arises dominated by arrogant and self seeking men, more intent on maintaining their power and its rewards than in serving labor and society as a whole. One of the most evident lessons of history is that human beings deteriorate in character and judgment when too much power is given them. Leaders of labor organizations are no exception to this rule, and society is finding that national organizations of all the workers in one industry irrespective of their trade, become tyrants.

"No absentee, autocratic labor leader will consider fairly the problems of the different conditions under which mining is carried out in various differing regions. He is too intent on making himself appear essential in the controversy to take into proper consideration the needs of the workers, and the rights of the public. A most striking illustration of this is the present coal strike. No one man can fairly represent the needs of the workers in both the bituminous and the anthracite coal mines. Inevitably he will use either one set of workers or the other as pawns in the struggle to keep himself in power.

"Why should a miner in Wyoming, who is perfectly contented with his wages and the conditions under which he works, be dependent for his right to work upon the policy of a man living in Indiana, who decides that miners working in Pennslyvania should strike in order to show that he is a power in the land? More intimate contact with the problem of each region is needed so that proper and fair agreements can be arrived at, that will allow the coal mining industry to continue its work of supplying fuel to the nation at a cheaper rate than any other nation in the world is supplied and at the same time pay its employees a higher rates of wages than is received by any other miners in the world."

Winding up the last general session, the Congress passed resolutions favoring impartial arbitration, approving the recent transfer of the Bureau of Mines to the Department of Commerce, commending Secretary Hoover for choosing the type of men he has selected to administer the Bureau's work, and endorsing the national safety competition now being conducted by the Bureau. There were other resolutions of interest only to metal mining men.

The arbitration resolution follows:

WHEREAS, The President of the United States in his message to the Congress has specifically endorsed the settlement of industrial controversies by impartial arbitration, and

WHEREAS, In order to terminate the present intolerable situation in the anthracite region, the operators have offered to submit all matters in controversy, without reservation, to arbitration, therefore,

BE IT RESOLVED, That the American Mining Congress places itself on record in support of the President's suggestions and endorses the principle of settlement of industrial controversies by arbitration.

The following officers of the congress were elected Friday:

President, Col. Daniel B. Wentz, Stonega Coal & Coke Co., Philadelphia, Pa.

Vice-presidents, Robert E. Tally, United Verde Copper Co., Jerome, Ariz.; E. L. Doheny, Los Angeles, Calif., and W. H. Lindsey, Napier Iron Works, Nashville, Tenn.

Secretary, J. F. Callbreath, Washington, D. C.

New member of the board of directors, George B. Harrington, Chicago, Wilmington & Franklin Coal Co., Chicago, Ill.

The last session connected with the congress was the luncheon of the manufacturers' division Friday noon where preliminary plans were made for the coal convention and machinery show of the congress next May. Bids are in from two or three cities for the convention. A committee composed of J. C. Wilson, Ohio Brass Co., L. W. Shugg, General Electric Co., and E. C. Porter, convention manager of the congress, was appointed to canvas the situation and make a final decision within two or three weeks.

A coal mining program to be arranged by the coal operating men of the country so as to satisfy their needs and theirs alone will be worked out. Mr. Wilson, who is chairman of the manufacturers' division, Ralph Becker, Keystone Consolidated Publishing Co. and Mr. Porter will begin at once to create a program committee that will carry out the plan. They will travel the coal regions soon so as to find out just what mining men want to have covered in the technical sessions next May.

As a tribute to Secretary Callbreath, who has been in the service of the congress ever since it was created—has been its mainspring, in fact—the manufacturers' division expects to have an oil painting of the Secretary made and hung in congress headquarters in Washington.

# The Anthracite Operators' Case Today*

By Samuel D. Warriner

Chairman, Anthracite Operators' Conference,
Philadelphia, Pa.

THE STATEMENT of President Coolidge that "perennial conflicts in the coal industry approached to a national economic failure," challenges the best thought of the American Mining Congress. There is no doubt that the disease to which the President directs attention exists. Its cure, however, may be delayed by the application of too many nostrums.

A public letter given out in the last few days by a distinguished group of nationally known engineers and economists, states that "no agreement will insure continuity of production and distribution which fails to provide a continuing joint agency that will concern itself with the constructive consideration of the underlying economic and technical facts" of the industry and that "joint effort on the part of management and workers in improving methods of production and distribution can increase wages and lift and stabilize earnings at the same time that they lower the price to the consumer."

**GOVERNOR PINCHOT'S POT OF GOLD**

**"THERE SHOULD never have been any attempt to impose the authority of government intervention upon an industry when the owners have consistently been willing to submit their case to impartial arbitration without reservation, and no judge, self-appointed or otherwise, should presume to render decision without at least hearing both sides of the case.**

**"From a practical standpoint, the governor of Pennsylvania might as well have divided a pot of gold at the end of a rainbow, as to expect his chimerical proposition would promote the interests of the industry and its workers and at the same time satisfy the reasonable expectations of the consuming public."**

The position of the operators, as stated to the joint conference at Atlantic City was and has since been in hearty accord with this expression of principle. Nevertheless, to date there has been an utter failure of negotiation and much misunderstanding on the part of the public as to underlying causes of such failure.

The basis of anthracite labor relations, since 1902, has been the award of the Roosevelt Commission. It preserved peace in the industry for 20 years. It provided a system of industrial negotiation and co-operation far in advance of its time. It endorsed in principle the open shop, but at the same time afforded full opportunity to union leadership. That the union progressed under its operation is a matter of history. While the theory of group representation in matters of joint negotiation was encouraged, it afforded every facility for the individual to express his grievance and to have his case determined by the joint board of conciliation, which was created by the award of the commission. The compensation of employees, under the sliding scale of wages, was determined to a certain extent by the economics of the industry.

The breakdown of this system came with startling suddenness in 1922, when John L. Lewis announced before negotiations were even begun that regardless of past practice, a strike would be called on April 1 if by that time a new contract had not been signed.

The objection of the Roosevelt Commission to the recognition of the United Mine Workers was that it was a bituminous organization. Before any recognition was granted by the operators, union leaders gave definite assurance that their anthracite policy would be autonomous.

Nevertheless, national union strategy influenced by bituminous policies has been substituted for the "men and management" plan of industrial government established by the Roosevelt Commission. This, together with the interjection of the strike as a weapon to be used first instead of last has produced industrial chaos. Since April, 1922, until the present time, a period of 44 months, practically 11 months or 25 per cent of the time has been spent in useless contention with appalling economic loss.

If you will study the history of the controversies of the last three years, you will agree with me that the basic issue has been the question of arbitration. The operators have consistently urged it; the union has consistently opposed it. No one believes arbitration to be a "cure-all," but the operators believe that, given full opportunity for negotiation, mediation, and conciliation, there still must be an agreement to arbitrate if strikes are to be avoided, and continuous operation of the mines, with dependable supply of fuel for the public, is to be assured. The influence of an arbitration board in the background is a powerful incentive to successful negotiation.

### Threatened Regulation Detrimental

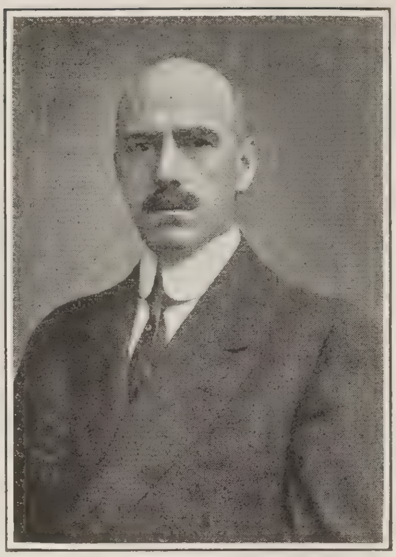
The spectre of government intervention, regulation and control, as well as the opportunities afforded for possible governmental operation or ownership, have often interfered with economic settlement of existing controversies.

The present attempted state intervention ignores commercial factors as well as all legal restrictions imposed by federal statutes. It assumes that prices can be maintained by agreement, and, on the basis of this assumption, that present wages can be maintained indefinitely, and surplus profits, if any exist, turned over from time to time by a commission to the miners in increased wages. No more impracticable theory of commercial operation can be imagined even by the most nimble mind.

No program by which prices can be maintained, or costs of operation other than labor controlled, is suggested. The fact that anthracite mine workers are receiving 10 per cent more than the highest war wages, and are already being paid higher than employees in other basic industries, is ignored. No banker or investor would loan money to such an enterprise. The acceptance of such a proposition would spell calamity to the industry. Yet the very proposal of such a plan encourages unreasoning expectation and impedes judgment.

---

*Address to the American Mining Congress Convention, Hotel Willard, Washington, D. C., Dec. 10, 1925.



Samuel D. Warriner

There should never have been any attempt to impose the authority of government intervention upon an industry when the owners have consistently been willing to submit their case to impartial arbitration without reservation, and no judge, self-appointed or otherwise, should presume to render decision without at least hearing both sides of the case.

### Dividing the Pot of Gold

From a practical standpoint the governor of Pennsylvania might as well have divided a pot of gold at the end of a rainbow, as to expect that his chimerical proposition would promote the interests of the industry and its workers and at the same time satisfy the reasonable and legitimate expectations of the anthracite consuming public.

At the opening of Congress it is pertinent to consider the possibilities of federal legislation. Unless it can be proven that anthracite is an essential and can command at all times a monopoly price, there is no warrant that the treatment accorded it should differ from the treatment accorded other mining and industrial enterprises. Any control of price inevitably presumes that whatever price may be set can be obtained. Control of methods of operation and distribution must conform to such regulations as are imposed upon other products of industry.

### Should Support Fact-Finding

The President should be supported in his recommendation that through some government authority essential facts shall be currently compiled. This eliminates at least one subject of controversy.

There should also be agencies of mediation and conciliation to promote voluntary arbitration. This is a manifestly sensible treatment, tending to make the strike, which is the cause of our troubles, more remote. The leaders of the labor movement would do well to follow the advice of Mr. Green, the president of the American Federation of Labor, who points out that labor unions have passed the militant stage, and must enter the stage of business co-operation if they are to retain the place to which they are entitled in our scheme of American industry.

Periodic strikes and suspensions of operation, whether caused by owner or employee, cannot be tolerated in one of the most important of our national industries. The common sense of the American people should compel peaceful adjudication of disputes by the rules of reason and logic, rather than by a resort to industrial warfare.

As President Coolidge says in his message to Congress, "Those who ask the protection of civilization should be ready to use the methods of civilization." The anthracite operators believe that out of this chaos will come an agreement embodying the "men and management" idea of industrial co-operation, with assured methods of adjusting disputes, and providing satisfying service to the American public.

**Good Roads Aid Development in Kentucky Coal Fields**

This road in Knox County, Ky., is constructed of concrete with an asphalt surface and links the towns of Pineville and Barboursville. These coal mining centers, formerly accessible only by train, are now also served by buses from neighboring towns.

# Book Reviews

## How It Should Be Said

The public is just beginning to value niceties of speech. Nothing more clearly brings home that fact than learning that the Westinghouse Electric & Manufacturing Co. has a literary critic and that he has published a book, "Principles of Business Writing," and that the publisher is none other than the Westinghouse Technical Night School Press, East Pittsburgh, Pa. The name of the author-critic is T. H. Bailey Whipple.

In the part of his book devoted to "Words and Phrases Often Misunderstood" he clears up for the reader many a moot point. Of course, we don't always agree with him. Stylists very seldom do agree. Language is fluid and changing. How much modern change we shall refuse to accept and how much accept no one knows. Nevertheless it is possible to find amazingly helpful a book with which you do not always find yourself wholly in agreement, and if you take Mr. Whipple as guide you will go a long way toward bettering your style.

### Grateful for Suggestions

We would not say, with Mr. Whipple, "has effected great advancement in the tone and character, etc." but rather "has bettered the tone and strengthened the character, etc." We would not refer to "a small amount of coal" but rather to "a small quantity" of that material. These, however, are details. We are grateful to Mr. Whipple for not a few happy suggestions, and have listed for our personal observance quite a few reforms that his apt advice has suggested. (Yes, he would approve that use of "apt.")

Slovenly English in letters, in reports, even in articles, often interferes with clarity. As one has said: "Words are like sunbeams, the more we condense them the deeper they burn." And we want our words to burn, do we not? We have a message to be delivered and we want it presented gracefully, courteously, correctly and not smothered in useless verbiage. To this end Mr. Whipple's book is dedicated. It contains 132 pp. measures 6 x 9½ in. and sells for $2. It has a chapter by G. M. Wood, of the U. S. Geological Survey, a stylist than whom there is perhaps none better.

---

## The Case of Bituminous Coal

With a series of lively texts from Gilbert and Sullivan operas and the "Bab Ballads," Walton H. Hamilton and Helen R. Wright, for the Institute of Economics, established in Washington, have produced a gloomy jeremiad that can be duplicated only by the choice of well-chosen parts of the Major and Minor Prophets.

To these investigators, and they appear to be well entitled to that name, for they have made a careful inquiry and seem to have their facts, if not all their deductions, straight, the coal industry appears to be getting more deeply involved every year. The promise of deflation made by the self-appointed physicians of the coal industry is not being kept, and the authors believe that just at present, despite depression in prices, inflation is rampant, every operator striving for increased production so as to lower overhead. To this tendency, the authors can see no end. The industry is sick, and its debility daily increases. The leucocytes by which its life blood should become purified are unable to overcome the germs that menace its healthy existence.

### The "Unhappy Complex"

The authors seem not to be unfavorable to the industry. In fact there are many operators who find themselves with the same unhappy complex as Hamilton and Wright. Like them they believe the skies will never clear. To a certain extent that is right. They never do and never can clear up entirely in matters mundane, but somehow the more cheerful of us at least can smile and go along with our work.

Pointing out that the demand for coal cannot be expanded except with the increase in population and general industry the authors say: "The hope for an increased demand for coal, if hope there can be, lies 'in the discovery of new uses for it.' But the only new use which a diligent search through trade periodicals reveals is 'to cool houses' in summer." That is no small use nor is it so greatly remote as this short reference would lead us to believe. Other uses that have been suggested are: larger domestic use by farmers who heat now only part of their houses, earlier and later operation of domestice fires, better and more general illumination and irrigation of farms by pumps in dry seasons. These are only indications of new uses. There will be many others that are not as yet knowable.

One should be a "bull" on the United States and industry without knowing just why. We are not troubling to name the statesman who in 1940 will meet the problems of that year and in some degree solve them, but we feel confident that he will be there. We are not naming all the new uses for coal there will be in 1940 or 1927 even, but we are quite well satisfied they are on their way, and *Coal Age* here and elsewhere has indicated some of them, only feebly perhaps.

### Will Open Other Inquiries

The book is so cheerless that it leaves one helpless and dazed but we are confident, nevertheless, that it will be made the first of a long series of jeremiads on the other industries. Overhead, overdevelopment, increased technologic efficiency, lack of vision, uncertain accounting, inability to weigh operating factors are difficulties in them all. In every direction of industrial inquiry the book on coal problems is almost always the first of such books to be written. The others follow in time. The reason is not difficult to find: Coal's illnesses are distressing for coal's services are so great. Consequently coal gets the most careful investigation and gets it first. The others follow. It is found that they are ailing too, though formerly no one cared, because either their immediate service was not needed or their abstention from work inconvenienced only a few members of the family. The science of industrial pathology starts with coal. When the subject is studied in that industry inquiries in others are soon added, the study being made in them not so much of dire necessity as because of a lesser advantage or out of mere curiosity.

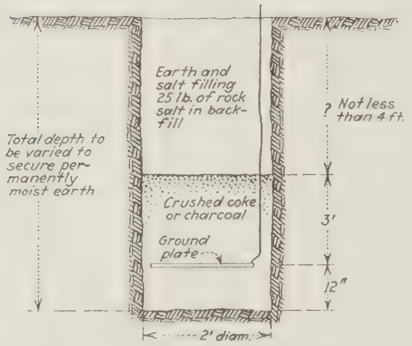
The book contains 307 pages measuring 4⅞ x 7¾ in. The publisher is The Macmillan Co. of New York City, and the price is $2.50.

# Union Pacific Coal Co.'s Code of Standards—I

STANDARDIZATION of method and equipment is carried to a high point by the Union Pacific Coal Co. at its operations in Wyoming. A new code of standards has been put into effect calculated to gain for the company all the benefits that are to be had from uniformity.

On these pages *Coal Age* begins the publication of the Union Pacific code and will, in future issues, publish the balance of it in a form that will permit of easy filing. This is done with the co-operation of President Eugene McAuliffe of the company, who practices helpfulness to the industry at every opportunity.

The standards as laid down in this code were made, of course, to cover the Union Pacific's Wyoming mines and would require modifications for use anywhere else. It was written after an exhaustive study had been made by the company's mining engineer after conferring widely with the operating and engineering staffs of many coal producing companies and after many mine inspections.



Earth and salt filling 25 lb. of rock salt in back-fill
Not less than 4 ft.
Total depth to be varied to secure permanently moist earth
Crushed coke or charcoal
Ground plate
3'
12"
2' diam.

**Fig. 1—Good Grounds Are Made**

This is the method used to obtain low-resistant ground connections for lightning arresters and electric machinery. Unless special means are used good grounds cannot be obtained in dry localities. Electric protective equipment is valueless without an efficient ground contact.

## Code of Standards

The mine foreman, who is held responsible under the law for the safety and general condition, of the mine and by the management for its production and costs, is recognized as the man in authority in the mine.

Mine electricians are expected to follow the orders of the mine foreman in performing routine work, repairs and the installation of such extensions as may be required in the regular operation of the mine. They will also receive orders from the local chief electrician as to general methods and special work when necessary.

The extensive use of electricity in our mines raises many problems that require a special training that a mine foreman should not be called upon to acquire.

The mine electrician should be impressed with the necessity of observing improper conditions and reporting them to the proper authorities with suggestions covering their remedy.

The following rules and regulations are to be considered as standards for the use of electricity both underground and on the surface at the mines of The Union Pacific Coal Co. They will be enforced, and are hereby understood to be in force and in effect as of this date.

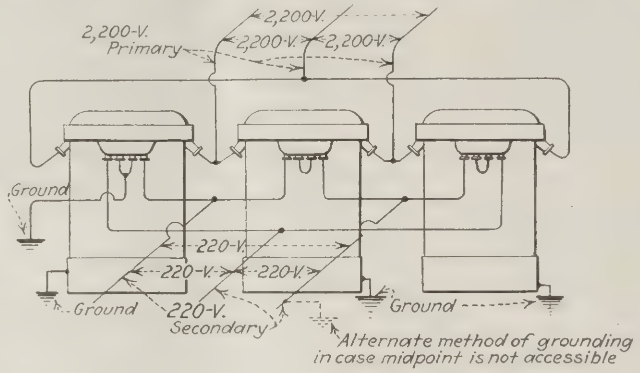


FIG. 2

**Permanent Grounds**

Transformer cases should be grounded in such a manner that the earth contact is not disturbed during ordinary inspection and repair work. If the midpoint of a transformer secondary winding is not accessible, one secondary line should be grounded.

### General Considerations

1. At each mine there shall be posted a plan map showing the mine wiring, cables, conductors and the location of permanently installed electrical machinery. The legend thereon will be as follows: Yellow, high voltage (2,200 volts); red, low voltage alternating current; brown, low voltage direct current, mining machines, pumps, hoists, locomotives, fans, etc., will be designated by note.

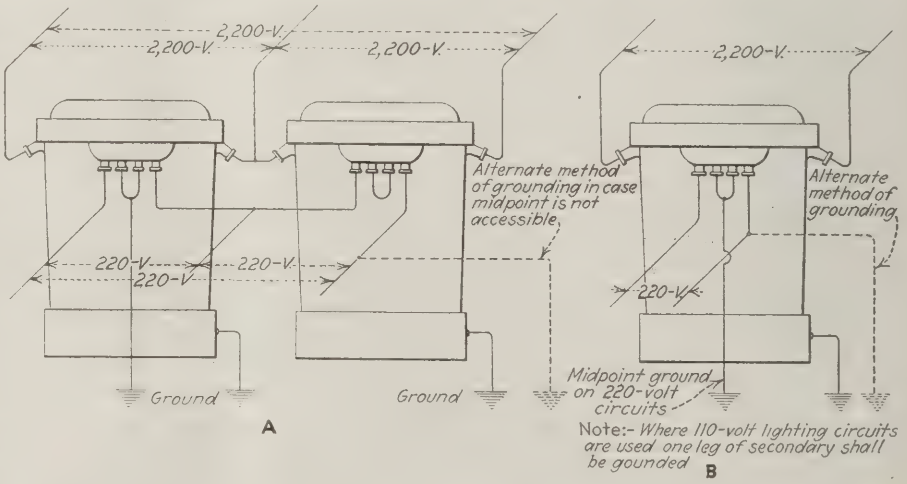
These plans shall be revised by the local chief electrician at intervals not exceeding six months, and oftener when necessary.

2. A rigid, systematic and careful inspection of all electrical equipment, cables and supply lines shall be made monthly, a report of this inspection to be forwarded to the office of the chief electrician.

(Note: This inspection shall cover the points outlined under heading—"Instructions to Persons Inspecting Electrical Equipment.")

3. In all future installations within the mines, the voltage shall not exceed 2,200. This potential may be brought in and applied to transformers, motor-generator sets, hoists, pumps or other apparatus upon the recommendation of the vice-president and general manager, and shall be installed under the direction of the chief electrical engineer. Mining machines, locomotives or small-capacity motors (less than 25 hp.) shall not have a voltage in excess of 275.

The exceptions to this are: The No. 40 Room hoist at No. 1 Cumberland; the Old No. 4 Panel hoist, in C Mine, Superior; the 100-hp. motor at No. 7 Mine, Winton; the 75-hp. motor No. 2 Mine, Rock Springs; the 50-hp. No. 4 Panel machine at No. 3 Mine, Winton; the 35-hp. motor, formerly used at No. 9 Panel, in C Mine, Superior; the 30-hp., No. 6 Panel hoist at C Mine, Superior; the 52-hp., No. 4 Panel machine in C Mine, Superior; and the mining machines and locomotives at mines Nos. 2 and 7, Rock Springs. These latter are to be subsequently changed to the lower voltage.



2,200-V.
2,200-V.

Ground
Ground
Midpoint ground on 220-volt circuits
A
Note:- Where 110-volt lighting circuits are used one leg of secondary shall be gounded
B

**Fig. 3—Protecting an Open-Delta and Single-Phase Connection**

*A*—The secondary circuit may be grounded either at the midpoint of a transformer winding or by making an earth connection to one of the line wires. In all instances the casings of the transformers should always be grounded. *B*—This arrangement is usually for lighting transformers but in all instances the tank should be grounded and also the midpoint of the secondary winding or a line wire.

4. All knife switches shall be of the safety inclosed type.

### Grounding

1. The frames, casings or inclosures of all stationary electrical apparatus such as motors, motor-generator sets, rotary converters, transformers, starting and control apparatus, oil switches, cable sheaths, or other equipment that accidentally may become charged with electric current shall be grounded. (By grounding is meant making a permanent connection to the general mass of the earth in such a manner as will insure at all times an immediate discharge of electrical energy to it without danger.)

2. All ground wires to be copper, not smaller than No. 4 B. & S. gage.

3. Ground wire connections to the apparatus shall be made by means of terminals soldered to the ground wire and securely bolted to the apparatus at such a point that its removal for inspection or repair will be unnecessary.

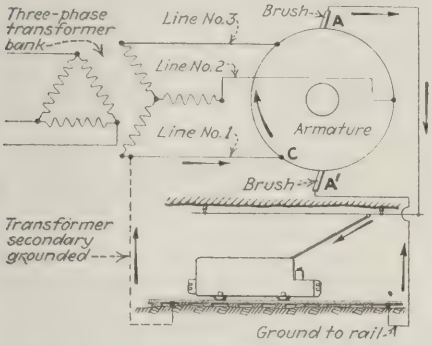

**Fig. 4—No Grounds Used on Transformers for Rotaries**

There is a physical circuit connection between the alternating-current energy and the direct-current supply in a rotary converter, consequently, since the direct-current system is normally grounded, another earth connection made to the secondary wires of the transformers creates a short current around a part of the rotary winding. For instance, if line No. 1 is grounded, current from *A* goes through the motor and returns to the rotary via two paths, one to *A'* and the other to the point *C* through line No. 1. Thus the section of the winding between *C* and *A'* is short circuited.

4. All ground connections shall be made to pipe lines, track or ground plates that are in contact with permanently moist earth; the connections to be mechanically secured and soldered. (See Fig. 1.)

5. All ground connections are to be approved by the local chief electrician.

6. Ground wires should be straight, and as short as possible and where necessarily run in pipe the ground wire shall be electrically bonded thereto.

7. Solid wire shall be used for grounds, except that flexible wire may be employed for connection to hinged or moving parts where it is necessary to make such connections.

8. Ground wires shall be installed in such a way that they can be inspected for continuity and be protected from mechanical injury.

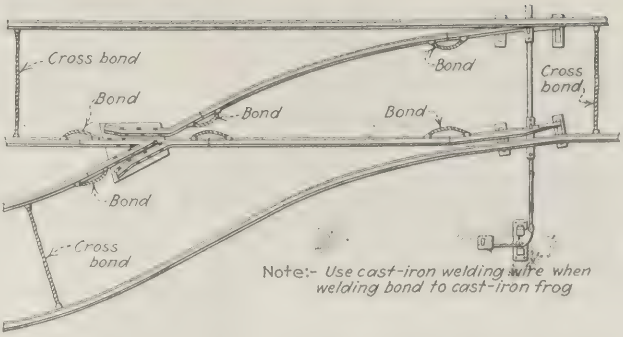
9. Transformer cases, oil switches and supporting frames shall be effectively grounded.

10. The secondaries of one transformer of each three-phase bank shall be grounded at the point which brings about the lowest voltage from ground to live conductor. (See Figs. 2 and 3.)

FIG. 5

**Bonding Around Switches**

A well bonded rail system may easily be spoiled by a poor arrangement of bonds at switches and turnouts. The aim should be to obtain a two-rail path for current both around the switch and to the tracks leading therefrom.



Cross bond
Bond
Bond
Bond
Cross bond
Bond
Bond
Cross bond
Note:- Use cast-iron welding wire when welding bond to cast-iron frog

11. Single-phase lighting transformers shall have the case and one side of the secondary grounded. (See Fig. 3.)

12. The secondaries of transformers supplying rotary converters shall not be grounded. (See Fig. 4.)

### Bonding

1. It is mandatory that all bonds found or known to be defective or broken be replaced on the same shift as that during which they are discovered or before the beginning of the succeeding shift.

2. All tracks used as a conductor for electric current shall be bonded at every joint and cross bonded at intervals not exceeding 300 ft.

3. Bonds at switches, frogs and turnouts shall be applied a shown in Fig. 5.

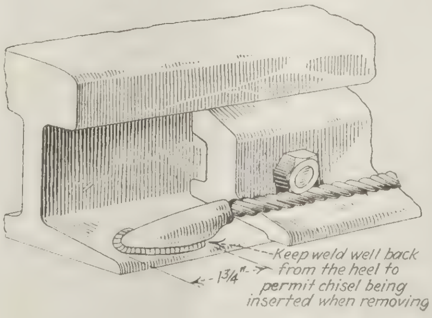
4. All bonds are to be of the arc-weld type welded to the base of the rail on the inside of the track. They must be of sufficient length to span the splice bars or fish plates. (Note: Bonds to be 4 in. longer than splice bars or fish plates.)

5. Bonds are to be welded to the rail in such a way as to give proper conductivity and permit of complete salvage. (See Fig. 6.)

6. All track bonding shall be given a thorough physical inspection every three months, and a report of findings forwarded to the chief electrician.

### Trolley Wires

1. Trolley wires shall be No. 4/0 B. & S. gage grooved and shall be supported on O. B. Cat. No. 11,309 type hangers, and O. B. Cat. No. 13,508 clamps or their equivalents.



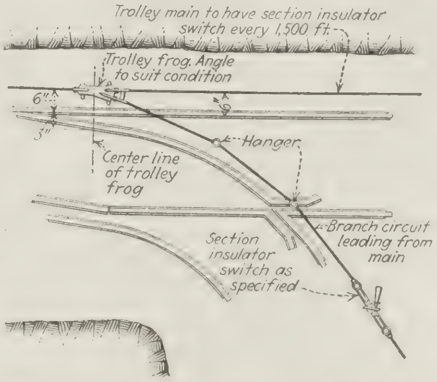
Keep weld well back from the heel to permit chisel being inserted when removing
1¾"

**Fig. 6—Where Welds Are Best**

The primary thought in applying a bond should be to obtain high conductivity at the joint. However, it should be done in such a manner that the bond may be completely salvaged. So that they will be better protected and yet be easily removed when it is necessary to do so bonds should be welded to the inside section of the base of the rail.

2. The height of the trolley wire above the rail shall be made as uniform as practicable.

3. Trolley wires shall be placed so as to give the maximum practical clearance and shall be kept in as straight a line as possible. They shall have a maximum height of not to exceed 6½ ft. and a minimum of not less than 4 ft.



Trolley main to have section insulator switch every 1,500 ft.
Trolley frog. Angle to suit condition
6"
3"
Hanger
Center line of trolley frog
Branch circuit leading from main
Section insulator switch as specified

**Fig. 7—Many Sectionalizing Switches Prevent Hazards**

Underground trolley circuits should be laid out so that a section insulator switch is located every 1,500 ft. in the line. Branch circuits should be equipped with a section insulator switch at the point where a tap is taken from a main trolley wire. Suitable signs indicating the location of switches should be placed along the line.

4. On straight runs the hangers shall be placed not more than 20 ft. apart where the height of the roof above the track is 5 ft. or less and not more than 30 ft. apart where the roof is more than 5 ft. above the track. On curves the hangers shall be placed sufficiently close together that the trolley wire at any one hanger may be entirely disconnected without exposing the locomotive runner to danger of contact.

5. Underground trolley circuits shall be sectionalized every 1,500 ft. by placing a switch in the line (similar to O. B. Cat. No. 11,600) by which the line can be entirely disconnected from the source of supply. All branch trolley lines shall be provided with a frog at the point where they leave the main and also with a switch (O. B. Cat. No. 11,600 or its equivalent) installed at or near the frog by which the branch can be disconnected from the main. (See Fig. 7.)

6. Appropriate signs designating location of disconnecting switches shall be placed along the line.

# News Of the Industry

## Pinchot Calls Special Session of Legislature to Regulate Anthracite; Governor Bitterly Attacks Operators

Governor Pinchot, still smarting under the operators' rejection of his "peace" program to end the anthracite strike, has again taken the offensive with a call for a special session of the Pennsylvania Legislature to meet on Jan. 13, 1926. At that time the Governor will ask the state lawmakers to enact measures to declare the anthracite industry a public utility and "to regulate through an appropriate state agency any and all of the businesses of producing, preparing, selling and distributing anthracite coal for domestic use." In addition, he will seek authorization of "compacts with any or all other anthracite-consuming states and the District of Columbia for the regulation of any or all of said businesses in the contracting states through an interstate commission or otherwise."

This is the second time that the Governor has urged state compacts under the tenth clause of the Constitution of the United States. In 1923, following widespread criticism of the manner in which he settled the strike in that year, he called a conference of his fellow governors and suggested state compacts as one solution of their complaints against high prices. The first conference was a fiasco; a second was a still greater failure from an attendance standpoint. At those meetings the state-compact idea was not only attacked but ridiculed. Governor Silzer of New Jersey declared it would take 31 years to get 31 states lined up. Governor Preus of Minnesota was a strong advocate of regulation through the device of declaring the industry a public utility.

### Scheme Failed Two Years Ago

The upshot of these conferences was that the Pinchot ideas in so far as they touched upon federal regulation of the anthracite industry were finally embodied in a bill which the Pennsylvania Senators at Washington declined to sponsor. Senator Borah then took the Pinchot legislative orphan under his care, but the bill was never pressed and there were no loud wails either in Washington or in Harrisburg when the measure died a peaceful death with the expiration of Congress. During the Harrisburg governors' conferences in 1923, Pinchot refused to entertain a proposal to issue a call for a special session, intimating that no favorable action by the Legislature could be expected. Attention was called at that time to the fact that a bill to declare anthracite subject to regulation had been introduced at Harrisburg by Representative Burns of Philadelphia and had made no progress in the regular session.

In announcing the call for the special session, which dockets giant power and a number of other subjects for consideration as well as coal, Governor Pinchot said:

"The present suspension in the anthracite region is a matter of the largest and most pressing importance not only to Pennsylvania but to all of the 40,000,000 anthracite-using people of America. It amounts to a dangerous crisis which must be met with promptness and courage.

### Cites Courtesy of Miners

"In an effort to settle the strike, as Governor of Pennsylvania I invited the negotiating committees of the anthracite miners and operators to meet me in Harrisburg on Nov. 18. The miners courteously honored my request by the attendance not only of their negotiating committee but of the entire membership of the scale committees of all three anthracite districts. The operators refused to attend and were not represented.

"At that meeting I submitted, as I said, the rough outline on an agreement upon which, in substance, I believe the present suspension of work in the anthracite mines could be, and ought to be, ended at once with justice to the miners, the operators and the anthracite-using people of America.

"This rough outline was a middle ground and was far from giving the miners all of their demands. Nevertheless, with a degree of moderation and regard for the public interest which does them high honor, they agreed to accept the outline agreement I proposed as a basis for settlement. If the operators had done the same the mines would have been open within a week.

"The operators, however, flatly refused to consider my rough outline as a basis for settlement. They refused to consider it even as a basis for conference and negotiation. From first to last they have refused to yield one jot or tittle of their original position. The anthracite coal strike, which was at first a strike of the miners against the operators, has therefore now become a strike of the operators against the public.

"The situation thus created amounts to an attack upon millions of anthracite users in Pennsylvania and other states, who are thus deprived of their customary fuel. The whole future of the anthracite industry is threatened by popular resentment and the use of substitutes. The prosperity of the anthracite region, now and hereafter, hangs in the balance. The public interests are gravely injured already and threatened with still more serious damage. Negotiations are at a standstill. The public must either suffer in silence or it must take measures to protect itself.

### May Regulate as Public Utility

"The anthracite industry is a monopoly which has created such a relationship to the public that the stoppage of anthracite production is materially dangerous to the life and health of the people. The Attorney General has advised me that under the clear intent of a recent decision of the Supreme Court of the United States the anthracite industry, being a monopoly, may be declared to be affected with a public interest and therefore subject to regulation as a public utility.

"Action by the Legislature declaring the anthracite monopoly to be a public utility will supply some degree of public control where none exists today; will furnish information never before revealed, and will exert the most powerful influence the public can apply toward the settlement of the strike. What is equally important, it will be the most effective step that can be taken toward securing uninterrupted prosperity for the inhabitants of the anthracite region

### *Widen Coal-Laden Sewer To Obtain Fuel*

Municipal buildings, including the fire houses and City Hall, of Shamokin Borough, Pa., in the heart of the lower anthracite field, having been without coal, making it necessary for clerks to work with the aid of electric heaters, the borough started mining coal for its own use last week.

A large sewer, built like a mine gangway, or tunnel, cuts through the Red Ash bed in the center of the town, and the Councilmen decided to widen the sewer and take out the coal for municipal purposes. Borough employees who also are experienced miners extracted the coal.

## Jail and Fine Pickets In W. Va. Strike Zone; Non-Union Output Gains

Monongah, the last stronghold of any consequence of the United Mine Workers in the heart of the Fairmont field, in northern West Virginia, continues to be the storm center in the present labor struggle. On Dec. 10 Judge Winfield Scott Meredith, in the Marion Circuit Court, passed sentence on 50 former pickets at the Monongah opening of the Watson mine of the Consolidation Coal Co., after deferring the matter several months. Patrick Buckley, president of Monongah local No. 1,643, who is a brother of Mayor Thomas V. Buckley of Fairmont, was fined $50 and sentenced to jail for 10 days. Ed Vingle, the leader of the Monongah miners' band, was fined $35 and given five days in jail. Twelve pickets were each fined $25; 24 pickets drew a $10 fine and 12 women pickets were each fined $1.

The miners gave notice of an appeal to the Supreme Court of West Virginia on the Buckley and Vingle charges and each gave bond in the sum of $1,000, pending Judge Meredith's decision. All the others paid their fines.

The Supreme Court of Appeals in Charleston on Dec. 8 heard argument on the writ of error granted to Van A. Bittner, chief international representative of the United Mine Workers in northern West Virginia. The court will pass on the matter at the January term, but it is possible that the case will not be reached until March 2. Bittner was sentenced to serve six months in the Monongalia County jail in Morgantown and was fined $100 on a charge of contempt of court by Judge I. Grant Lazelle in Monongalia County several months ago. Bittner then obtained a writ of error. The alleged contempt was made in a speech which Bittner delivered in Fairmont.

The miners' office in Fairmont was busy last week distributing clothing to the striking miners and their families. Various trade unions all over the country are sending cast-off clothing and the international organization is said to have spent $12,000 recently for new clothing that was distributed. The miners continue to hold group meetings in the region.

*Keystone View Co.*

**Col. John J. Byrne**

Appointed chairman of the State Fuel Commission last week by Gov. Al Smith of New York. Colonel Byrne has been prominently identified with state military affairs for many years and commands the 244th Artillery Regiment of the National Guard. He succeeds Major General Charles W. Berry, who was elected Comptroller of New York City in the November election.

Recently the Marion County Court met and dismissed a number of deputy sheriffs, believing that the disturbances in the mining towns were growing less numerous daily.

Non-union coal production continues to mount daily. A new daily non-union peak was attained Dec. 9, when 2,049 carloads was produced. In the first four days of last week the mines at work on a non-union basis produced 7,930 carloads of coal compared to 7,217 cars in the corresponding period of the previous week. Union mines loaded 1,136 cars of coal in the same period compared to 1,173 cars in the first four days of the preceding week.

On an average there were 226 non-union mines at work daily in the region during the first four days of last week. In the same period 14 mines worked on a union basis. Not a union mine worked on the Monongah Division, B. & O., for seven workdays, until Dec. 10, when a union mine resumed operation. The backbone of the union is on Scotts Run, where 13 mines operated daily.

---

and an uninterrupted supply of anthracite for those who need it."

Formal statements on the Governor's latest move had been withheld by spokesmen for the miners and the operators up to the time this issue of *Coal Age* went to press. Announcement was made, however, that Major Inglis had called a meeting of his associates to consider the situation. The Governor followed up his proclamation with a summons to the mayors and burgesses of the cities and towns in the anthracite region to confer with him at Harrisburg on Dec. 16.

A further gesture toward legislative action in the situation was made a few days ago when Democratic Congressmen from New York went on record as favoring the enactment of a resolution to have the President appoint another commission to investigate and report not later than Feb. 1, 1926. Governor Silzer of New Jersey, transmitting a petition from the Board of Commissioners of Jersey City, wrote Washington that he hoped federal action to end the tie-up would be taken. The business men of the anthracite region, after an abortive meeting with Governor Pinchot on Dec. 8, appealed directly to the operators and miners for a resumption of negotiations, but without evidence of success.

Late reports from the mining districts indicate that the pinch of the suspension is being felt by the strikers. Many miners are on the ragged edge financially and some cases of actual privation and suffering have developed.

---

## Hint of General Strike In Southwest

Likelihood of a strike throughout the Southwestern coal field was hinted in an announcement, Dec. 8, from headquarters of District 14, United Mine Workers (Kansas), following the return of J. V. Fitzgibbons, joint board member, from a conference with John L. Lewis, international president, in Springfield, Ill. At the meeting were representatives of districts 13, 14, 21 and 25, comprising Iowa, Kansas, Oklahoma, Arkansas and Missouri, the same districts that were represented in Kansas City in two or three secret meetings preliminary to the one in Springfield.

"Violation and abrogation by the coal operators of the joint agreement in the Southwest was the subject matter of the conference," the district 14 statement said. "A policy of procedure was agreed upon and a committee from the international union will visit the Southwest at once to decide whether violations of contract by operators, particularly in District 21 (Oklahoma), will justify a cessation of work by all union men in the four districts represented at the conference."

James Sherwood, state mine inspector, of Kansas, announced recently that the number of mines now operating in the state exceeds by more than 100 the number open at this time last year. All are working full time.

## Advisory Committee Approves Mine Bureau Plans

The recommendations of its subcommittees in regard to the reorganization of the Bureau of Mines were approved by the full Advisory Committee which met in Washingotn Dec. 12. These recommendations embody the plan for the creation of an economic branch, for the transfer of the coal and minerals divisions from the Bureau of Foreign and Domestic Commerce and certain mineral statistics from the Bureau of the Census.

Some objection has arisen to the actual rescue operations of the Bureau of Mines crews. The committee has no thought of recommending anything that would pave the way for the building up of a great mine-rescue activity. The desire is to concentrate safety work on matters of instruction and demonstration, but the committee does not see how it can restrict rescue operations when the Bureau's cars are near enough to a disaster to render aid when it is requested by the state authorities and the mine operators. Actual participation in rescue work, however, will continue to be an incident to the operation of rescue cars.

All of the recommendations which have been approved thus far are to be drafted in final form at once. The next meeting of the Advisory Committee will be held in Washington the last week in January. On that occasion the committee will meet with Director Turner, who by that time will have had an opportunity to familiarize himself with the application of the changes which have been suggested. Mr. Turner expects to begin his active duties immediately after the first of the year.

## Smokeless Operators Told Of Increasing Esteem for Non-Union Coal Producer

Never before have the non-union coal operators of the country stood so high in the public esteem. This point was expressed by J. A. Emery, chief counsel for the National Association of Manufacturers, during remarks at a luncheon of the Smokeless Coal Operators' Association of West Virginia held in Washington Dec. 10. The public is beginning to realize that it has much to be thankful for because of its great independent source of fuel supply, he said.

Mr. Emery praised the effort being made by the West Virginia operators to co-operate in a study of the "problems, the responsibilities, the rights, and the great duties" of their industry. The operators are co-operating, he said, in an effort to improve the service that they are rendering the public. While it is possible to obtain co-operation in such things, he expressed the opinion that it would be as difficult to get men accustomed to matching their judgment against that of competitors to become a part of a monopoly as it would be to get a chorus made up of prima donnas.

Mr. Emery condemned the tendency of some individual producers to be dissatisfied with association work if they do not receive $2 worth of service from the association for each dollar which they expend in dues. Much of the benefit of association work, he asserted, must be general, just as the sanitation of a city preserves the general health and is highly commendable, despite the fact that an individual who may have an attack of gallstones must call in a physician. The public is beginning to learn, he stated, that business men can co-operate and still be competitors.

Co-operation, Mr. Emery said, must be judged by its objectives. If it is used to the disadvantage of the public it is not only illegal but it is immoral. He compared such co-operation as that of the smokeless operators with that of the United Mine Workers. In the latter instance, he pointed out, the avowed purpose is the building up of a monopoly to fix wages regardless of its effect on the public. Were industry to attempt any such thing, he said, there would be an outburst on the first page of every yellow journal in America.

**Col. W. D. Ord**
Re-elected President by Smokeless Operators

The organized effort of national organizations to combat government interference with private industry and to limit the competition which the government may maintain with taxpayers was cited by Mr. Emery as indicative of the disapproval being aroused against the assumption of economic functions by the government, in addition to its proper political functions. He said there is little to fear from the soap-box socialist, for whom the public has little time, but the socialist is not so easily recognized in the habiliments of a U. S. Senator, he pointed out.

Colonel W. D. Ord was chosen to serve a second term as president of the association. E. J. McVann was reelected secretary. Major L. Rodman Page, Jr., was selected as first vice-president; Major W. P. Tams, Jr., second vice-president, and G. H. Caperton, treasurer. On the Board of Governors the Winding Gulf Association will be represented by A. J. King and C. Hooper Mead; the Pocahontas Association by Major L. Rodman Page, Jr., and T. F. Farrell; the Tug River Association by J. T. Wilson and J. L. Steinbugler; the New River Association by G. H. Caperton and D. B. Wentz; the Greenbrier Association by J. B. Laing.

## Cost of Locomotive Fuel Advances Slightly

There was little change in the quantity and average cost per ton of coal used by Class 1 railroads of the United States in locomotives in transportation train service during September as compared with August, according to figures compiled by the Bureau of Coal Economics of the National Coal Association. Figures prepared by the bureau show the following averages: Eastern district, $2.67; Southern district, $2.19; Western district, $3; United States, $2.67.

Variation from August totals was slight; there was a decrease of 3c. per ton in the average for the Eastern district, an increase of 3c. in the Southern district, an increase of 2c. in the Western district and an increase of 1c. for the entire country. Compared with September a year ago the figures show a decrease of 31c. for the Eastern district; 17c. for the Southern district; 16c. for the Western district and 24c. for the United States.

Tho total cost of coal and fuel oil for the first nine months of this year was $241,401,019, as against $265,771,476 for the first nine months of last year. This saving of $24,370,457 resulted partly from a decrease in the price of coal and partly from economies effected by the railroad management.

## John A. Bell Convicted of Embezzlement of $600,000

John A. Bell, well-known Pittsburgh coal operator, was found guilty Dec. 8 of embezzling more than $600,000 from the Carnegie Trust Co. of Carnegie. The maximum sentence under the twelve counts in the indictment is sixty years' imprisonment and $60,000 fine.

Bell also was president of the First National Bank of Carnegie and the Burgettstown National Bank of Burgettstown. Both institutions closed their doors following the Carnegie Trust Co. crash. The Carnegie Coal Co., controlled by Bell, is second only in size to the Pittsburgh Coal Co. in western Pennsylvania. He also controlled other large mining operations. At one time Bell's fortune was estimated at $25,000,000 to $30,000,000.

## Bituminous Coal Loaded Into Vessels at Lake Erie Ports During Season to End of November

(In Net Tons)

# Suppression of Coolidge Reply To Lewis Threat Piques Public; Executive Intervention Distant

**By Paul Wooton**

Washington Correspondent of *Coal Age*

Interest in the President's reply to John L. Lewis has been fanned into a flame by the unexpected withholding of the letter from the public. The general assumption is that Mr. Coolidge took advantage of the opportunity to point out with entire frankness what he thinks of the threat to call a strike in the union fields. Many express regret that the spanking was not done publicly instead of in a dark closet. As this is written the general expectation is that the text of the letter never will be made public.

The President's message to Congress, however, gives more definite form to the administration's coal policy. While the President in general only repeats the recommendations contained in the first Coolidge message, it is possible in the light of events of the past two years to get a clearer picture of his intentions. What was then vague now is understood.

Observers in Washington see in the message a definite commitment to a policy of non-intervention until sufficient authority is given to allow the executive to take steps that would have a chance to be successful. The President does not favor a policy of complete aloofness as it is apparent that he would approve legislation which would provide for the following:

(1) Fact finding and publicity, presumably through the Bureau of Mines, as the Department of Commerce is mentioned specifically.

(2) Encouragement of regional consolidations and the authorization of co-operative marketing associations.

(3) Authorization for the secretaries of Commerce and of Labor to undertake mediation proceedings.

(4) Authorization to direct the distribution of coal during emergencies. This apparently means nothing more drastic than the issuance of priorities and the control of rail distribution along the lines of the Fuel Distribution act of 1923.

### What Does the President Mean?

The least definite of the foregoing is the suggestion concerning mediation. Those interested in the President's views, both inside and outside of Congress, would like to see him elaborate this point. Does Mr. Coolidge mean the tendering of good offices through some Cabinet officer? If so, that would not differ greatly from the present conciliation work of the Department of Labor. Does he mean compulsory investigation and report to the President in the event of a big strike without compulsory acceptance of the findings as recommended by the Coal Commission? Would he set up machinery for voluntary arbitration?

Though the President's program clearly embraces the points enumerated, it is obvious that he is not pressing his ideas on Congress. His attitude rather is that Barkis is willin'. The center of interest, therefore, has shifted to Congress, where the action likely to be taken will depend largely on the anthracite strike. If the strike is settled without great public inconvenience there would be little chance for legislation. This would happen not so much because Congress is averse to dealing with the matter but because the other business crowding for attention then would appear to be relatively more important.

### Much Depends Upon the Weather

An unusual number of coal bills have been introduced or are under preparation. If the strike should drag on with little prospect of settlement or if Mr. Lewis should create the impression that a bituminous strike is imminent, the prospects would be favorable for obtaining some sort of legislation. The chances would be increased greatly were there to be a period of severe weather. Thus far this autumn the weather man has been with the operators. Were the weather to turn colder it might reveal a condition of unpreparedness which thus far the mild weather has covered up.

## Utilities Consume More Coal And Oil in October

Public utility power plants in the United States consumed 3,699,207 net tons of coal in October, according to a report by the U. S. Geological Survey. This compares with 3,471,638 tons in September, as shown by revised figures. Fuel oil consumption by utilities in October totaled 837,741 barrels, compared with 807,406 barrels in September as shown by revised figures.

The average daily production of electricity by public-utility power plants in October was 191,300,000 kw.-hr. More electricity was generated by electric public-utility power plants in the United States in October than ever before. The daily output exceeded that of September by nearly 5 per cent and that of January, whose daily rate was next to September, by 6½ per cent. The output in October of this year exceeded that of October, 1924, by more than 14 per cent. The total output for the 4-month period from July to October of this year was 15 per cent greater than for the same period in 1924.

## *British Coal Subsidy Nearly Doubled*

A supplementary allowance of £9,000,000 for the coal mining subsidy, bringing the total voted to £19,000,000, was adopted by the British House of Commons, Dec. 10.

Winston Churchill, Chancellor of the Exchequer, in moving the vote, explained that 90 per cent of the subsidy had gone directly to wages.

Over the whole coal fields the mine owners were making scarcely any profit, he asserted, but were just able to keep themselves going. He estimated that the total cost of the subsidy would approach £21,000,000.

**William L. Abbott**

Newly elected president of the American Society of Mechanical Engineers, who assumed office Dec. 4. He is well known as the foe of coal waste, having been chairman of the committee of the American Engineering Council which conducted a nationwide study of coal storage in co-operation with the Department of Commerce and the U. S. Coal Commission.

## Fraud Warning

Warning has been broadcast by the Post Office Department of a fraudulent coal-selling scheme perpetrated by J. W. McCarthy, who at various times has operated under the name John Webster McCarthy, the Kanawha-Hazard Coal Co. and the Wood Coal Co.

By means of false financial statements and other false representations he induced coal operators to ship on his orders without paying the operators, the coal being shipped and billed with the name of his company as the shipper, and the purchaser remitting direct to him or his company. He also secured advance payments for anthracite by furnishing the prospective purchaser with false bills of lading in some instances, and in others by merely representing that the coal would be or had been shipped. He succeeded in swindling several coal companies in West Virginia, Virginia, Pennsylvania and New York.

McCarthy was indicted at Charleston, W. Va., May 27, 1925, for using the mails to defraud. He was arrested in New York Oct. 14, 1925, and furnished bail in the amount of $17,000, but has since defaulted and his present whereabouts are unknown.

## Winding Gulf Mining Men Honor E. E. White; Make Snyder President

The Winding Gulf Operators Association at its seventeenth annual meeting in Washington, D. C., Dec. 9, accepted the resignation of E. E. White, who has been president of that association for seventeen consecutive years and honored him with a luncheon and an elaborate watch and chain. Mr. White retires because he has disposed of his holdings in the district to the Massachusetts Coke & Gas Co., and temporarily, at least, severs his connections with West Virginia smokeless coals to give closer attention to his banking and mining interests in the anthracite fields of Pennsylvania.

The association elected P. M. Snyder, of Mt. Hope, W. Va., president; W. Gaston Caperton, of Slab Fork, vice president; George Wolfe, of Beckley, secretary, and A. W. Laing, of McAlpin, W. Va., treasurer. The following were elected to serve on the executive committee: A. W. Laing, C. H. Mead, L. Epperly, W. B. Beale and T. H. Wickham.

At the testimonial luncheon Mr. Snyder, the newly elected president, presided and after a few appropriate remarks turned the meeting over to John Laing, who acted as toastmaster. Outlining the condition of Raleigh County some twenty years ago, when Mr. White first entered the field, and clearly defining the vision and progressive action in policy carried out under the leadership of Mr. White, the various speakers emphasized the high regard and esteem in which the coal industry of southern West Virginia holds Mr. White and the great regret that is felt at his departure.

E. E. White

Among those who spoke were W. J. Harahan, president, Chesapeake & Ohio R. R.; S. M. Adsit, traffic manager, Virginian Ry.; D. E. Spangler, superintendent of transportation, Norfolk & Western Ry.; Harry L. Gandy, executive secretary, National Coal Association; E. J. McVann, secretary, Smokeless Coal Operators' Association; A. M. Belcher, attorney, from Charleston, W. Va.; Holly Stover, Chicago; Rev. H. P. Pullin, McKeesport, Pa.; George W. Williams, attorney, Beckley, W. Va.; A. M. Dudley, coal freight agent, Chesapeake & Ohio Ry.; George I. Neal, attorney, Huntington, W. Va.; William McKell, Glen Jean, W. Va.; Frank Wadleigh, New York City; A. J. King, Huntington, W. Va.; Ernest Chilson, Raleigh, W. Va.; G. H. Caperton, president, New River Coal Co., Charleston, W. Va.; W. Gaston Caperton, Slab Fork, W. Va., the first secretary of the association, who served for ten years in the early days; J. Lewis Bumgardner, attorney, of southern West Virginia.

---

The Bureau of Mines has tentatively accepted the invitation from the Safety Engineers of California to hold the 1926 International First-Aid and Safety meet in San Francisco. It is planned to alternate these annual affairs between the Far West and the Middle West.

## *Indiana Miners Rescue Three From Explosion and Fire*

In the Columbia mine, near Bicknell, Ind., on the morning of Nov. 27, while three miners were loading cartridges preparatory to shooting down coal, a keg of blasting powder exploded near them, hurling them some distance and inflicting severe burns on all three.

Edmund Capon and August Boury, who were working near the entry in which the explosion occurred, dashed through the curtain of fire and dragged two of the victims back to safety. Realizing that a third man remained in the burning entry, Capon fought his way back through the smoke, disregarding the danger of further powder explosions.

Boury, waiting outside, heard a faint cry above the crackle of the flames. Stripping off his shirt and soaking it in water, he wrapped it about his head to guard against inhalation of gas fumes and flames, and dashed after Capon. He stumbled over the latter's body, where he had fallen by the prostrate form of the third victim of the explosion. Grasping the shirt collars of Capon and the blast victim, Boury dragged both back through the flames to the main entry. Though painfully burned, it was not until he had assisted in taking the four men to the surface and had aided in placing them in ambulances that Boury submitted to first-aid treatment for himself.

Physicians pronounced the burns of three of the men serious, and the condition of the fourth was said to be critical.

## Disturbances Break Out at Pittsburgh Coal Co. Mines

After a period of uninterrupted operation at the mines of the Pittsburgh Coal Co. in western Pennsylvania, where the 1917 scale is being paid, two disturbances took place in quick succession at Montour No. 10 mine, at Library, and at Midland mine, at Houston. A small-sized riot occurred at Library Dec. 8 and early the following morning a double house owned by the company at Midland mine was dynamited. A family in the building escaped uninjured.

The Sunday before the riot at Library union sympathizers had beaten two negro miners, and on Wednesday a truck which had been carrying supplies to the mine was stoned by a mob of men and women. The driver lost control of the truck and it crashed into the crowd, killing one woman and injuring several other persons. Several deputy sheriffs at the mine also were injured in the fracas. Fifty warrants were sworn out and deputies are still serving them.

Immediately after the trouble the company stated that instead of curtailing operations at the plants, they had increased. By the end of the week the working force had risen to a new maximum of 1,088 men. There were 225 men at work at Library and 303 at Midland. On Tuesday the Pittsburgh Coal Co.'s legal department started eviction proceedings against ten miners living at Library and several at Midland. The houses are needed for men willing to work at the mines.

---

### Higher Study in Rescue Work

The U. S. Bureau of Mines has just completed a course of advanced instruction in rescue and recovery operations following mine fires and explosions for the Davis Coal & Coke Co., Thomas, West Virginia. This new department of the Bureau, the Safety Extension Service, under the direction of J. J. Forbes, chief engineer, and his assistant, George Grove, in three weeks trained and issued certificates to forty-seven employees of the company. Certificates also were conferred on three directors of rescue stations and one mine inspector in the State of West Virginia. Also a certificate to one mine inspector from the State of Maryland. The course will be given to a limited number of employees of the same company at Boswell, Pa., some time in December. Upon the completion of the instruction this company will have approximately sixty men trained in the advanced work.

---

### Rainey Miners Get Free Powder

The W. J. Rainey Co., the largest independent coke producer in the Connellsville, (Pa.) field, has ended the long dispute over payment for blasting powder used by the miners. In the past a certain portion of the miner's wages was deducted for the powder used in blasting. This nearly caused a strike several times. The company has issued an announcement that in the future blasting powder will be furnished to miners free of all charge.

## Fifty-Two Lose Lives In Gas Explosion in Alabama Coal Mine

A gas explosion in Overton No. 2 mine of the Alabama Fuel & Iron Co., eleven miles from Birmingham, Ala., at 10:30 a.m. Dec. 10 exacted a death toll of fifty-two miners and company employees. Nine of the dead were white and forty-three negroes, most of whom were married men with families. Most of the fatalities resulted from the heavy volume of afterdamp which spread rapidly through the workings, only those in the near vicinity of the blast being burned.

Immediately following reports of the disaster Charles F. DeBardeleben, president of the company; F. E. Cash, S. E. Saxon and Dr. Merriweather, local U. S. Mine Rescue Station officials; Charles H. Nesbitt, chief state mine inspector, and several associate inspectors rushed to the scene with the Mine Bureau car, and equipment and crews were immediately organized for the rescue work and went into the slope. The bodies of seven negro miners were first removed and a number of men who were slightly injured and overcome by the fumes were taken to hospitals. These were found above the entry in which the explosion occurred. The blast occurred in Room No. 7 on the 6th right entry about 2,000 ft. from the opening, and in this entry the greatest number of dead were found. The death toll was large also in the 7th right and 6th left entries.

Rescue crews have been constantly at work since the disaster and all the dead with the exception of two white men have been removed from the mine. The two bodies still in the workings are supposed to be buried under a large rock fall which occurred in 6th right entry and it is understood that it may require several days to remove this rock and recover the last of the victims. According to the records of the company 108 men went into the slope on the morning of the disaster.

The No. 2 Overton Slope, located 11 miles northeast of Birmingham, has been driven to a depth of about 3,000 ft. All inside workers are provided with electric cap lamps. Coal is mined by pick and the only electric cables in the mine are those supplying current to the pumps, none of which were located in the vicinity of the blast. It is a single-track slope, the coal being hoisted by an electric engine. The mine was not rock dusted but was thoroughly sprinkled and watered by the latest approved methods. Excellent ventilation was provided and the best means of eliminating danger from gas were employed. No open lights or matches were permitted. Permissible explosives were used exclusively. The mine is modernly equipped, the best known safety practices being followed by the management, which provided regular instruction both individually and collectively in accident prevention.

Officials of the state mining department, the U. S. Bureau of Mines and the operating company have made only a preliminary examination of the workings and will give out no official opinion as to the cause of the explosion.

**Community Center Developed From Publicity Stunt**

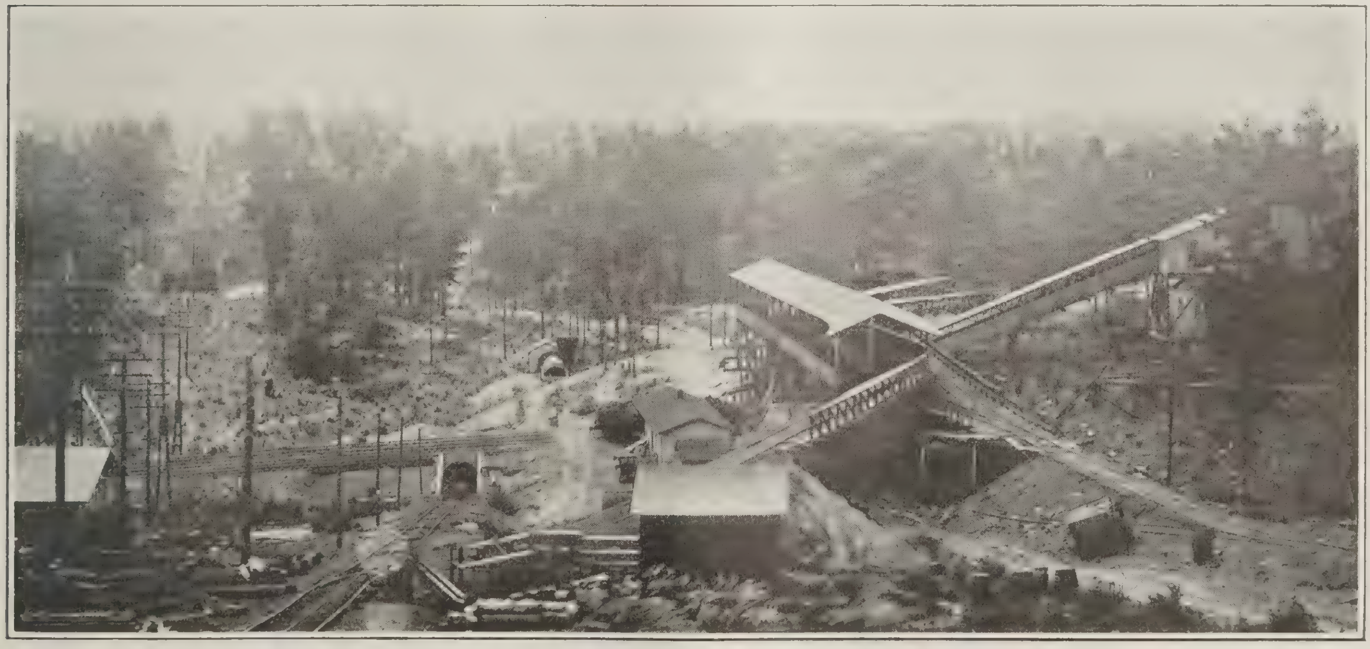
This advertising scheme created by P. J. Emt, Seattle coal dealer, consists of a fireplace set in the wall of a living room in a modern Colonial type bungalow. Two comfortable benches are set before the hearth. The display can be seen for several blocks, particularly at night, when the fire is burning. The fire, of glowing Diamond briquets, is lighted in the evening and little community gatherings are held, charmed by the homey atmosphere of the display.

## C. & N. W. Will Try Out Oil-Electric Locomotives

The Chicago & Northwestern Ry. is seriously considering the use of oil-electric locomotives in the Chicago switching district and the Chicago suburban territory. Two of these locomotives have already been procured for initial tests whch will begin soon and last two months.

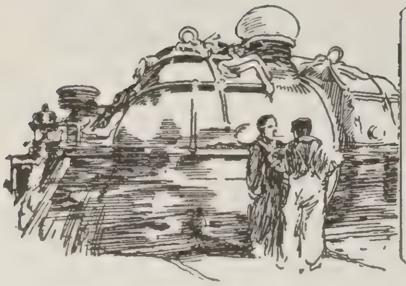
The locomotives to be used are of the Diesel internal-combustion type. The Diesels will be used to drive electric generators, which in turn will furnish power to drive the electric motors. The first locomotive was designed and built by the General Electric Co., the American Locomotive Co. and the Ingersoll-Rand Co. It will weigh about 60 tons and will develop 300 hp. The second locomotive, which weighs 100 tons and develops 600 hp., was designed and built by the Westinghouse Electric & Mfg. Co. and the Baldwin Locomotive Works.

The Jersey Central and Long Island railroads have been testing oil-electric locomotives for nearly a month.

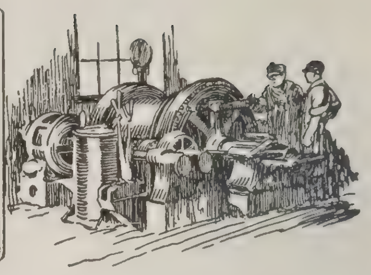


**Exterior View of Overton Mine of the Alabama Fuel & Iron Co.**

Showing main slope, tipple and washery of the operation where fifty-two men were killed in a gas explosion Dec. 10. Two seams are worked at this mine, which is located about 12 miles from Birmingham, Ala. The opening of the main slope can be seen in the left center of the picture. The building at the right, partly hidden by the trees, is the washery.



# Practical Pointers For Electrical And Mechanical Men



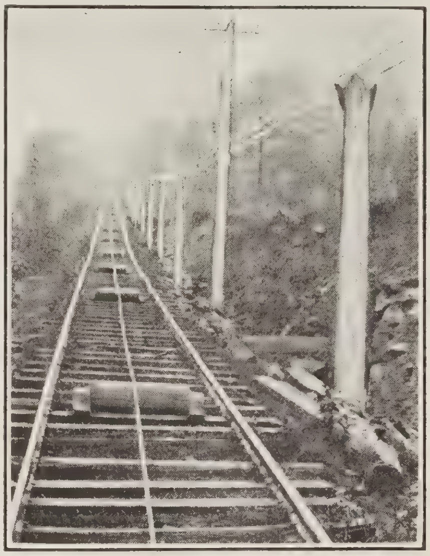
## Operator of Long Incline Can Be Signaled from Moving Car

At drift mines where the seam outcrops on the side of a mountain high above the railroad it is necessary to have a man-and-material incline. Many of these inclines are of such length or contour as to make it impossible for the hoist operator to see the car during its full travel. In such cases it is of advantage to have a method of signaling the operator from the car while at any point enroute. The Southern Mining Co. has such a method at its Balkan, Ky., mine.

An example of the desirability of such a signal system was demonstrated but a few minutes before the accompanying photograph was snapped of the incline leading up to the mine at Balkan. It happened this way: At the end of the day when the last man trip was coming down, a cow walked out on the track. To a stranger on the car it appeared that the truck was soon to be wrecked by reason of the cow. However, in order to signal the operator to stop the car one of the men reached for a copper rod kept on the truck and was about to touch it across the pair of bare signal wires, which parallel the track, when the cow suddenly decided to get out of the way.

### Presents Neat Appearance

These signal wires are supported on short poles spaced 40 ft. apart. Every third pole is a longer one and on the tops of these long poles the telephone lines are carried on steel cross arms. This combination signal-and-telephone line is of sturdy construction and presents a neat appearance. The signal wires are high enough above the ground to escape damage by live stock and yet low enough to be touched easily with a copper rod by a man standing on the truck. Provision for signaling the operator to stop or start the truck at any point is an advantage, also, when repairing the track or rollers.



**Signal Wires Are Within Reach**

A man riding on the truck can signal the operator to start or stop by reaching out with a piece of wire or metal rod and shorting the wires.

## Topworkers Now Have Good Drinking Water

No mammal, with the possible exception of the camel, can long endure the heat and strain of a hard day's work without a periodic refreshing drink—water of course, being the beverage alluded to. Until a few years ago most men at the mines carried whatever water they needed with them when they went to work. Because of their employment in localities that are decidedly remote many underground workers must still, perforce, follow the same practice. Bottom and upperworks employees, on the other hand, now-a-days usually are provided with drinking water at convenient locations near their places of employment.

The accompanying illustrations show one of the drinking fountains (Fig. 1) installed at the mine of the Valier Coal Co., Valier, Ill., as well as the small brick structure in which it is housed. This particular fountain, which is one of several at various locations about the plant, is intended for the use of tipple hands and yard men. It is, therefore, installed beside the hoist house and at the rear of the yardmens' shanty, a portion of which may be seen in Fig. 2.

The brick structure in which this fountain is housed provides adequate protection from the weather. Enough heat will be admitted during the winter months to insure against freezing and a cinder floor will keep the place dry. The fountain itself is white enameled and provision is made for filling glasses, cups or other receptacles.

During the past few months the Valier Coal Co., has been installing an excellent system to provide drinking water about its plant. A small hydraulic pump placed in the shop building provides pressure for this system. This draws its power from an elevated tank and is entirely automatic in its operation, the opening of a spigot fountain starting the pump. The water supplied comes from a deep well located some dis-

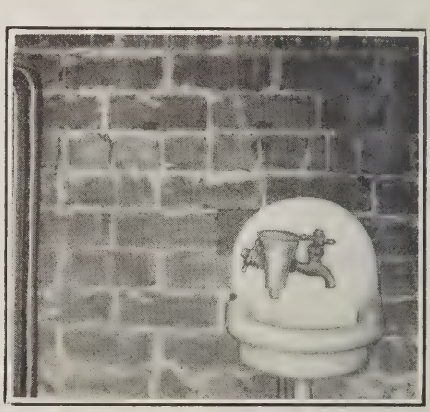


**Fig. 1—Topworks Drinking Fountain**

This is intended to furnish good drinking water to the tipple and yardmen. It is installed in a small brick structure in rear of the hoist house. Enough steam will be admitted to the radiator on the extreme left to keep the pipes from freezing even in the coldest weather. A tamped cinder floor in this building assures that it will always be dry.

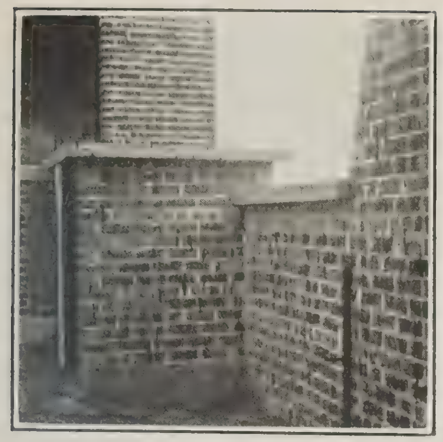

**Fig. 2—Building in Which Fountain Is Housed**

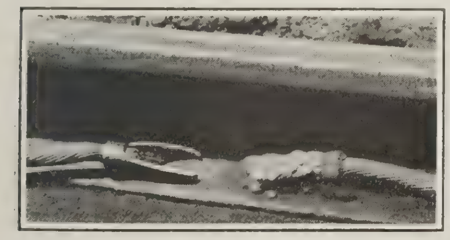
This little structure is provided with a concrete slab roof. The large building to the left is the hoist house and that to the right is the yardmen's shanty. On the extreme right is the chimney serving the fireplace in this latter structure.

tance from the mine shaft. The arrangement is such that an ample supply of wholesome drinking water is available to the employees at all times.

## Copper Welded Terminal Makes Good Bond

Welded bonds have come into general favor because of their high conductivity and permanency of the contact when properly applied. A new type of welded bond is shown in the accompanying illustration. The original photograph was taken at No. 8 mine of the Fordson Coal Co. at Stone, Ky. To make the picture effective an unwelded bond was placed with the terminal in the welding position beside a bond which has been applied and in use for some time. This particular bond was one of the first of this type installed, which accounts for the rather rough appearance of the weld.

The steel terminal is not intended to act as a conductor. Its purpose is to act as a mold and to add mechanical strength. The welding is done by an electric arc and a copper electrode. C. B. Loche, electrical engineer of the Fordson Coal Co., states that he was early convinced of the advantage of welding with a copper electrode and that for some time before these bonds were available he had advocated such a terminal as that just described.



**Copper Electrode Makes Joint**

The terminal shown on the left is designed so as to form a mold into which the copper electrode is deposited. The unit then becomes a copper-to-steel contact.

## Wire Rope Supports Chute For Slate Disposal

Old wire ropes removed from shafts, slopes, and inclines are used in a number of ways about the mines. An unusual application is that of supporting a slate-disposal chute, as shown in the accompanying illustration.

At this mine, that of the New Caryville Coal Co., Caryville, Tenn., the new dump house is at the head of a long monitor plane, and is near a ravine in which there is a large dumping space for slate. To carry the slate from the tipple to the edge of the ravine, where dumping could be started, a 50-ft. chute was necessary. Instead of building a trestle to support this chute, two old cables from the monitor plane were used as a suspension.

**Chute Supported on Ropes Obviates Trestling**

At the mine of the New Caryville Coal Co., Caryville, Tenn., old ropes removed from monitor service form a suspension support for a refuse chute. The lower end is anchored to trees and the upper end to a rock ledge above the tipple. The chute will be extended down along the ropes as new dumping space is required.

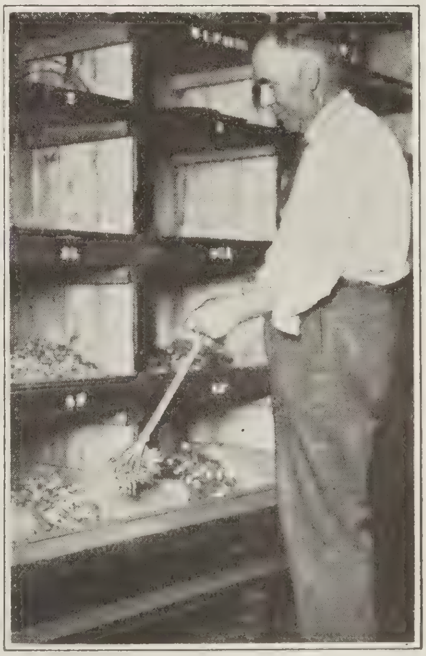
These cables are anchored at the lower end to a couple of trees located about 200 ft. down the ravine. At the upper end the ropes pass over a saddle just below the cross-over dump, and are anchored to a rock ledge. As necessary, the chute will be extended down along the ropes to discharge at a new position.

The dumping of the slate from the mine cars into the chute is handled on the same cross-over dump as the coal. This eliminates the necessity of cutting slate cars out of a trip. When a car thus loaded reaches the dump, a fly gate, which normally forms a section of the bottom of the chute, is raised to a vertical position thus opening a hole through which the slate drops into the disposal chute.

## Fingered Tongs Convenient For Handling Nails

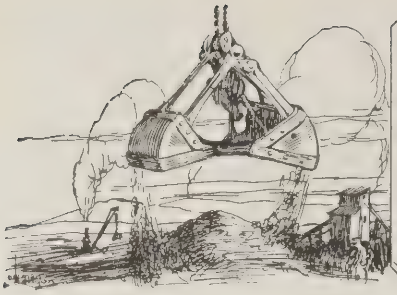
Taking care of the warehouse, storeroom, or storehouse, as it is variously termed at different mines, is usually a one-man job, and this man spends much of his time doing office work in connection with maintaining and dispensing the stock. One item of material particularly in demand, especially at mines where the coal company owns and maintains the houses, fences, and so forth, is that of nails; and no insignificant part of the warehouse man's time is taken up in filling orders for them.

Ordinarily he "digs" the nails out of a bin with his fingers. Before returning to his work in the office he must stop to wash. Even this simple job of dispensing nails can be made much more pleasant, and can be done in half of the time, by the use of the proper tool. In the illustration is shown the eight-fingered tongs used in handling nails at the Earlington warehouse of the West Kentucky Coal Co. This tool, which was made by the mine blacksmith, picks up a bunch of nails in much the same way as a man would pick up a double handful with his fingers. Several pounds can be picked up at one grab.



**An Easy Way to Handle Nails**

This photograph, taken in the Earlington warehouse of the West Kentucky Coal Co., shows how the home-made tongs are used in dispensing nails.



# Production And the Market

## Coal Market Suffers from Effects of Politics, Buying Habits and Mild Weather

Several efforts to bring the hard-coal operators and union leaders together to resume negotiations that would bring about a settlement of the anthracite strike having come to naught, Governor Pinchot's proclamation calling a special session of the Pennsylvania Legislature to begin Jan. 13 occasioned little surprise. Although seven other subjects are listed for consideration there is little doubt that the difficulty in the anthracite industry will occupy an important place in the deliberations of the legislators. It is still worthy of note, incidentally, that despite the approach of January the consuming public displays no unwonted interest in the suspension, the principal insistence on action to bring about a resumption of mining coming from the business interests of the mining region. Meanwhile the tendency to hold back, awaiting results, probably will continue to be in evidence, with a belief in the background that such tactics certainly will not lend any aid to an upward trend in the prices of substitutes.

Failure to release for publication the contents of President Coolidge's reply to John L. Lewis' veiled strike threat in appealing for government intervention in the bituminous coal situation has heightened public interest in the letter from the White House, but as the reason assigned for its suppression was a desire not to interfere with Governor Pinchot's efforts for peace in the hard-coal region it is not likely that the President's reply will ever be published.

### Soft Coal Weakens Further

Softness in the bituminous coal market is becoming more marked, due to a combination of untoward circumstances—from the standpoint of the trade. Buying habits, as exemplified in the customary tapering off in orders with the approach of the holidays and inventory taking, in conjunction with the usual readjustment following the close of the lake season has had an unsettling effect on conditions. Generally mild temperatures and the maintenance of production at a high level have added further weight to the depression.

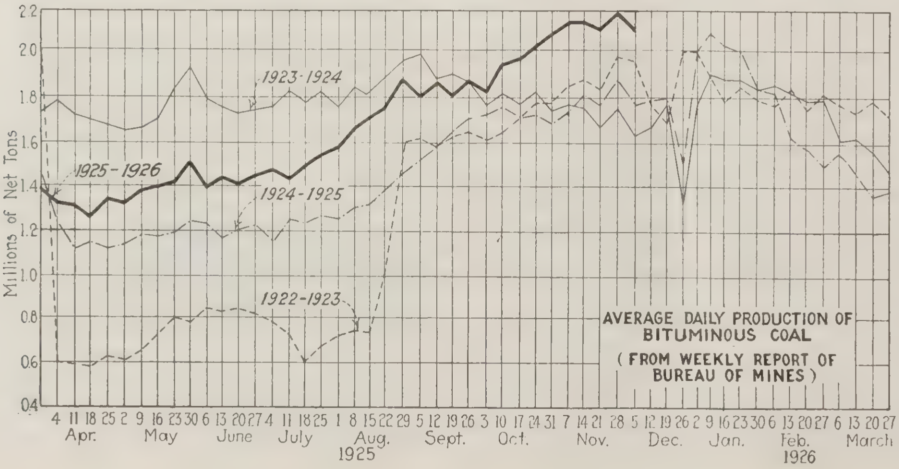
Save for an occasional cargo of pea and No. 1 buckwheat in New York Harbor, hard coal is virtually off the market. Consumers continue to show a growing interest in coke, though retailers are chary about increasing yard stocks, preferring to play a waiting game as long as possible.

### Output Still Hitting High

Production of bituminous coal during the week ended Dec. 5 is estimated by the Bureau of Mines at 12,768,000 net tons, which is the highest weekly tonnage reported since Dec. 11, 1920. This compares with an output of 11,600,000 tons in the preceding week. Anthracite output in the week ended Dec. 5 totaled 62,000 net tons, a gain of 26,000 tons over the previous week. Total output since Jan. 1 is 61,945,000 tons, which is 26 per cent less than that of the corresponding period of 1924.

*Coal Age* Index of spot prices of bituminous coal stood on Dec. 14 at 182, the corresponding price being $2.20, compared with 184 and $2.22 on Dec. 7.

Dumpings of coal at Lake Erie ports during the week ended Dec. 13, according to the Ore & Coal Exchange, were as follows: Cargo, 107,301 net tons; steamship fuel, 3,866 tons—a total of 111,167 net tons, compared with 363,225 tons in the preceding week. Hampton Roads dumpings during the week ended Dec. 10 totaled 337,558 net tons, as against 464,217 tons in the previous week.



**Estimates of Production**

(Net Tons)

| | 1924 | 1925 |
|---|---|---|
| **BITUMINOUS** | | |
| Nov. 21 | 10,910,000 | 12,596,000 |
| Nov. 28 | 9,885,000 | 11,600,000 |
| Dec. 5 (*b*) | 10,831,000 | 12,768,000 |
| Daily average | 1,805,000 | 2,128,000 |
| Cal. yr. to date | (*c*) 443,981,000 | 480,679,000 |
| Daily av. to date | 1,556,000 | 1,679,000 |
| **ANTHRACITE** | | |
| Nov. 21 | 1,827,000 | 46,000 |
| Nov. 28 | 1,611,000 | 36,000 |
| Dec. 5 | 1,814,000 | 62,000 |
| Cal. yr. to date | (*c*) 84,172,000 | 61,945,000 |
| **BEEHIVE COKE** | | |
| Nov. 28 (*a*) | 160,000 | 293,000 |
| Dec. 5 (*b*) | 174,000 | 299,000 |
| Cal. yr. to date | (*c*) 8,865,000 | 9,656,000 |

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Consigned Coal Depresses Midwest Trade

Developments of the last week in the Midwest market show that operators have not yet learned their lesson on the subject of consigned coal. One company producing smokeless coal consigned enough of prepared sizes to Chicago to break the market to smithereens. When some of it was on demurrage it was unloaded to a wholesaler at $3 for lump, $3.20 for nut, and $3.50 for egg—and it was standard coal. Western Kentucky operators and West Virginia splint operators, as well as some in eastern Kentucky, did the same thing.

The market on domestic coals has been extremely unsatisfactory, due to mild weather and the high prices brought about by the last buying flurry. Operators have not been able to get enough business on a day to day basis to run their mines and have had either to fall back on old orders taken a month ago, ship coal on consignment or close their mines. Only a few closed their mines, but those few are reputed to be the best merchants in the game.

West Virginia splint domestic coals are offered freely on the basis of $2.50 for lump and $2 for egg. Eastern Kentucky coals can be had at $2.75 for lump in hoppers and $2 for egg in hoppers. Eastern Kentucky coals in flat-bottom or low-side cars are about 25c. higher. West Kentucky lump has been coming into Chicago on consignment as low as $1.75, and by lump is meant 1¼-in. steam lump but 6-in. shaker-screened boom-loaded domestic lump. Indiana domestic coals have been uniformly weak. The only outfits who are apparently holding their prices are the big operators in Franklin County and in southern Illinois.

Steam coals seem to be in fairly good demand, as producers are having no difficulty in disposing of what coal they have on hand from day to day. Prices are firm, but not enough to warrant the slightest increase. There was a flurry a week or so ago when some of the bigger industries purchased their December requirements, but this has subsided and the steam-coal market now is going along in an uneventful and steady way. It is anticipated that if it becomes much more difficult to move domestic coals there will be an increase in steam-coal prices.

Mild weather has shown its effect in the movement of coal from the Williamson, Franklin and Harrisburg fields. Lump seems to move easily, but egg is not moving freely and nut and the smaller sizes are blocking the tracks. Some mines report moving lump under pressure but everywhere there are "no bills," although the mines show fairly good working time. Railroad tonnage from shaft mines reported good. In the strip mines working time is good, with a ready market, although prices vary. Railroad tonnage from strip mines also is good. Duquoin and Jackson County mines are working four and five days a week and coal is hard to move, with "no bills" always on hand. Mt. Olive conditions show improvement. Railroad tonnage has eased off but steam

## Current Quotations—Spot Prices, Bituminous Coal—Net Tons, F.O.B. Mines

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Dec. 14 | Dec. 7 | Nov. 30 | Dec. 15 |
| Index | 182 | 184 | 187 | 169 |
| Weighted average price | $2.20 | $2.22 | $2.26 | $2.04 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1924, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

demand keeps up for the northern market and domestic tonnage is fair. Reports have it that poor preparation has seriously affected the market for this coal. In the Standard field there is no change. Coal is sold at about cost of production. There are always "no bills" on hand and there seems to be a surplusage of coal over demand. Mines are working three to four and sometimes five days a week. Railroad tonnage is reported good. Cars have been plentiful in the past week and the movement of coal better than for six weeks on the part of the roads. Prices are unchanged.

At St. Louis warm weather eased off the demand for domestic locally although there has been a little moving, principally of the cheaper grades. High-grade Illinois has been moving under pressure, with very little call for smokeless or anthracite, though coke is doing fairly well. Country domestic is fairly good, for the cheaper coals principally, with a heavy volume of western Kentucky coming in west of the river and eastern Kentucky coming in east of the river. Country steam is easy.

### Softness Appears in Kentucky

Practically all coals are weaker in Kentucky as a result of very mild weather, good car supply, heavy production, lack of demand, and shading on the part of some jobbers and producers in an effort to force retailers to take on more coal. There doesn't appear to be so much distress fuel or "no bill" cars on track in eastern Kentucky but some lots of fifty to a hundred cars have been offered at considerably under the markets.

Movement into various districts has been good, but as production in all sections is heavy, many mines in eastern and western Kentucky are keen for business. Though prices in western Kentucky are being fairly well maintained in so far as quotations are concerned, some shading is being done to move "no bills," and it is reported that tonnage has eased up somewhat. This is reflected by stronger markets on screenings, which are in demand, with production curtailed due to lack of movement on prepared.

The eastern Kentucky market may be quoting some block coal at above $3.50, but the market to the trade is $3@$3.50 through the jobbers. Lump is $2.75@$3; egg, $2.25@$2.75; nut, $2@$2.50; mine-run, $1.50@$1.75; screenings, $1.10@$1.40, the latter being considerably weaker. Western Kentucky block is $2@$2.25; lump, $1.75@$2; egg, $1.60@$1.85; nut, $1.35@$1.50; mine-run, $1.25@$1.50, and screenings stiffer, at 80c.@$1.10.

### Northeast Trade Comparatively Good

While the movement of coal from the docks at Duluth and Superior has fallen off in the last ten days as compared with the peak period of last month, operators report a good volume of business. Industrial demand is satisfactory, with shipments going over a wider territory than for several seasons, trade in southern Minnesota that had been supplied from Illinois and Indiana mines having been regained since the upward readjustments in freight rates.

Demand from the Minnesota iron-range district has slowed down since the conclusion of ore shipments for the season. Retailers have been ordering small tonnages at a time, but with the necessity of more frequent buying, the trade is reaching good proportions.

Shipments from the docks during November were 27,411 cars, compared with 31,685 cars in October and 28,765 cars in November last year. Shipments in December have been lighter than in November.

Receipts from Lake Erie docks in November totaled 976,978 tons, bringing the aggregate for the season to Nov. 30 to 8,665,616 tons, an increase of 1,214,163 tons as compared with the same period last year. Last month 5,400 tons of anthracite was brought over from Fort William and delivered to a briquetting plant at Superior, making hard-coal receipts for the season 796,248 tons, a falling off of 474,457 tons as compared with last season.

Supplies of Pocahontas and other smokeless coals, as well as domestic coke and briquets will be available in good tonnages as substitutes for anthracite consumers. Figuring that difficulty may be experienced in supplying prepared sizes of Pocahontas by the first week in February, dealers have been trying to induce consumers to accept mine-run Pocahontas. Progress has been made in the campaign, with the wide spread in quotations a consideration. Quotations are steady for both anthracite and bituminous coals, no changes having been reported lately. Pocahontas prepared sizes are $8.50@$9; mine-run, $5.25@$5.50, and screenings, $4.25.

Milwaukee dock managers report business rather quiet at present, but they expect betterment with the beginning of the new year. Prices continue unchanged. The last cargo of the season of 1925 has arrived from the lower lakes, bringing the December receipts of bituminous coal up to 128,957 tons. No anthracite has been received since Sept. 15.

### Lump Backs Up in Kansas

Continued mild weather has reduced the demand for coal in the Southwest to the point where sixty or seventy cars of lump are standing on Kansas tracks and some mines in Arkansas are idle part of the time. Kansas operators have maintained full-time production, with all sizes other than lump moving as produced. Only a few days of cold weather would be required to pile up orders again.

In Utah the demand for slack is a little better than the supply. Slack and domestic lump are moving faster now than other grades; nut and lump are said to be slowing up. The market as a whole might be described as fair. Weather conditions have not been entirely satisfactory from the standpoint of the coal trade thus far, except for one or two days. Industrial demand is about normal for the season, or a little better. Retailers say business is better than for several weeks. The car situation is good and "no bills" on tracks are kept at a minimum. Prices remain steady.

Continued warm weather, particularly in Nebraska and Kansas, has caused a sudden slump in orders for future delivery of Colorado domestic and steam coal. Operations of the mines has been reduced to about 85 per cent of capacity. No cancellations are coming in, but orders for future delivery are being held in abeyance pending further advices.

### Realignment Unsettles Cincinnati Market

Readjustment of smokeless-coal prices almost amounted to a rout at Cincinnati last week. Under the influence of small accumulations, lack of buying interest and the usual seasonal disinterestedness the spot market on lump slipped within ten days from $5@$5.25 to $3.50@$3.75. These lower prices were on "spot," "distress" or "no-bill" cars, however, as the old line dealers who sold on contract for the month at $5 and $5.25 are billing coal to their customers at the old level. Egg fared a little better, "spot" holding at $3.75@$4 for Western delivery. Mine-run was not greatly affected, maintaining its range of $2.25@$2.50. Screenings, through the fact that byproduct takers are careful on coke sales and require less, is soft at $1.75@$2.

In high-volatile there has been a tendency to softness that cannot be actually reflected through quotations. After West Virginia offerings dipped to $2.50 for low-grade lump there was a bit of a recovery with the market holding fairly well at $2.75, but late in the week it did not take much bargaining to get $2.50 6- and 4-in. lump once more. Southeastern Kentucky producers tried to hold their market at $3, a drop of 25c. In most instances they were successful, though late week prices showed some quotations going out at $2.75. Egg prices were clipped off to a general range of $2@$2.25. Mine-run held firmer, what reductions there were coming on gas, byproduct and the higher gradings. The slip here generally was about 10c., though the low grades were fairly well held around $1.45@$1.50. Screenings were sagging. Low-grade Kentucky hit bottom around 90c. to the trade. About the lowest quotations on West Virginias were $1. Higher priced slack, however, made no rapid descent so that the general average was maintained at $1.10@$1.15.

There has been no change in the retail situation.

High temperatures have had a weakening effect on the domestic trade in Columbus and central Ohio. Retailers are buying only in small lots, as their stocks are ample to take care of the reduced demand. The public is asking for splints and high-grade Kentucky product in preference to Pocahontas and other smokeless varieties because of the wide spread between the prices. Ohio grades are moving fairly well when the warm weather is taken into consideration. There is only a small amount of free coal on the Columbus market and further reductions in prices are not expected at this time. Demurrage coal is not reported in central Ohio, although there is a considerable tonnage in Detroit and Toledo.

The steam demand continues irregular and spotty, prices having suffered to a certain extent. A few short-time contracts, extending for 60 to 90 days, have been closed recently.

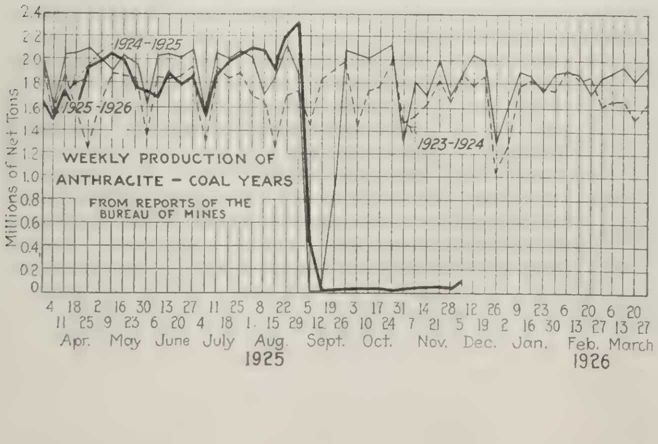
Production in the southern Ohio field is about 30 per cent of capacity.

There is little if any change in the eastern Ohio situation, except that spot prices of slack and nut-and-slack have eased off, being 10 to 15c. per ton less than those prevailing a week ago, and the quantity available is easily meeting the demand.

In the steam trade buyers are slow to make purchases other than for current needs.

Retail yards are pretty well loaded up, as domestic buying has not been heavy since the scare of some six or eight weeks ago. Pocahontas lump is quoted at $3@$3.50 f.o.b. mines, today, as compared with $5@$6 six to eight weeks ago. Other West Virginia and eastern Kentucky domestic lump is now $2.50@$3, f.o.b. mines.

During the week ended Dec. 5 eastern Ohio production was 339,000 tons, or about 48 per cent of potential capacity. This was 42,000 tons over the output of Thanksgiving week and 70,000 tons over the corresponding week a year ago.



### Pittsburgh Trade "Relatively Poor"

The Pittsburgh market continues in relatively poor condition. Buying of domestic coal by retail yards has, if anything, decreased. Industrial consumption continues heavy, but buyers are very reserved about making commitments.

Open-market demand for gas coal is quite limited, as has been found by some Connellsville operators seeking a market for a little surplus. The regular consumers seem to be covered in large part by contracts running to April 1. Slack continues firm at recently advanced prices, indicating limited shipments of lump.

Prices for Pittsburgh district coal are only a trifle above the level of last summer, when they were as low as they could possibly go.

The aspect of the Buffalo coal situation changes pretty often, but it never seems to benefit the straight bituminous situation. That is as dull as ever and it promises to remain so till the strike is settled, when it is expected that there will be a period of no demand to speak of. Sometimes one sort or another gets a trifle scarce, but the prices do not vary visibly.

### New England Market Still Slipping

In New England the market for steam coal reflects a further decline. Prices are off even from the levels of a week ago, and there is only scattering inquiry for spot bituminous of any character. The smokeless agencies at the Virginia terminals as well as rehandling factors at this end are striving to place a volume consistent with current mining, but further curtailment will have to be resorted to if spot prices are not to drop to a still lower range. Notwithstanding special rate dispensations the flow of prepared sizes north from the Pocahontas and New River fields is by no means as heavy as predicted; retail dealers have taken on about all of this fuel they can conveniently absorb and the consumer is being advised on every hand to confine his requirements to mine-run. Even public fuel committees are now saying that a mistake was made in dwelling so much on the advantages of lump, egg and chestnut from the smokeless districts. Meanwhile the low-volatile producers in Pennsylvania enjoying the Clearfield rate are keeping tight hold of the market they developed before the through rates from Pocahontas and New River were ordered.

Current prices on board vessels at Hampton Roads for No. 1 navy standard coals are wobbling around $5 per gross ton, with occasional sales at materially less than that figure. No possible buyer is allowed to escape, and the trade is being assured that mine-run is now carrying a higher percentage of coarse coal than was the case a few weeks ago. Shipments coastwise on contract are about normal, although water freights have eased somewhat under the influence of better supply.

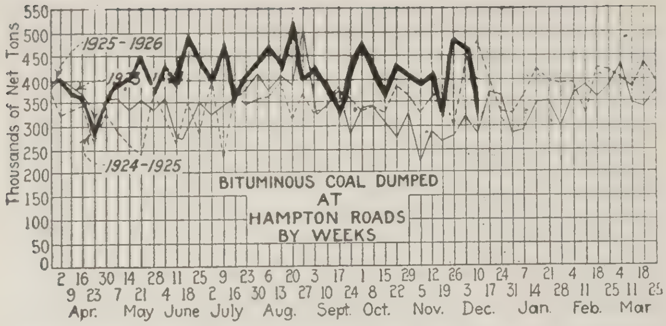
For inland delivery prices on cars at Boston and Providence have slumped similarly, the former level of $6.50 having been shaded 25.@40c. the past few days. At Providence there seems to be an especially ragged market.

Continued mild weather is the apparent reason for so little anxiety over the depleted stocks of anthracite. The public mind is resting in security, as far as this territory is concerned. The small proportion of householders who have thus far been forced to buy substitutes are mild in their comment and seem quite reconciled. As yet there is nothing approaching a panic and no indication of an acute shortage of fuel later on.

### Trade Steady at New York

New York is using soft coals in larger quantities in place of anthracite. Although there has been a slight drop in demand for mine-run coals, buying is steady and the urging of the State Fuel Commission that they be used instead of hard coal seems to be bearing fruit. Demand is much less than it should be, mostly due to weather conditions, but this is expected to be speedily overcome with the first stretch of low temperature. Meantime dealers are buying carefully and in small quantities.

Shipments of New River and Pocahontas sized coals to



Long Island have been greater than the demand, with the result that distress coal has been let go at less than current market quotations. There has been some rejections of shipments because of indifferent preparation. Quotations for egg and nut sizes range $4.75@$5.50.

Screened coals from central Pennsylvania are quoted at $3.50@$5, according to quality and preparation. Broad Top egg and nut are $6.35@$7.

Purchases are in good volume at Philadelphia, but there is no particular anxiety on the part of the consumer about getting fuel. Business in sized coals has been disappointing during the past two weeks, high volatiles from western Pennsylvania and northern West Virginia having declined from $5 to almost half that price, with no business. Low volatile is a bit better, but even these have declined sharply. A fair volume of Pocahontas and New River sizes is coming in, but coals that sold for $7 a short time ago are now plentiful at $5 and even 50c. lower.

Rail fuel continues in good volume, and inquiries for good tonnages are abroad. Tidewater trade is extremely light. Bunkers are fair, some interests reporting a slight increase. Prices, though not particularly strong, are well maintained.

The fuel trade at Baltimore has been quiet in the last two weeks. While best grade coals are holding fairly well, lower grades in many cases can be bought considerably off the so-called average quotations. The flurry that attended sales of prepared sizes of high volatile coals, used as substitutes for anthracite, has come to an end. Such coals, which in October and part of November brought as high as $5.50 for egg, are now freely quoted at $2.15@$2.25. Coals for industrial use are, if anything, a little weaker than a week or ten days ago. Pool 71 continues about on the same level, but high grade Pool 9, which ten days ago brought $2.05@$2.10, is offering at $2@$2.05. No exports are reported.

Production in the Alabama field is now being speeded up to the limit to fill the heavy requirements of the trade for current consumption and holiday storage. All mines are operating full time with maximum production. Inquiry is good for all grades of steam fuel and coking coals are especially strong and the supply of the favorite qualities rather limited. Industrial consumption is unusually large, and the railroads and utilities are also taking abnormally large quantities. The bunker trade is still very active at the Southern ports, the mines usually supplying this class of business being pressed to fill requirements along with their other heavy business for washed coal.

Domestic coal is still moving very well and most operations have orders to carry them over the holidays. Inquiry is continuing good, but due to lack of protracted cold weather, consumption is not especially heavy and demand for prompt movement is not quite so insistent at it has been.

Quotations are without any material change from a week ago, the strong position of the market maintaining a firm schedule of prices.

Carriers in the Birmingham district have maintained a fair car supply for all operations of late and there has been little if any loss of time on this account. The district is now producing around 425,000 tons per week.

### Hard-Coal Trade Now a Waiting Game

With the exception of some cargoes of pea and No. 1 buckwheat, with occasional tonnages of rice, anthracite is practically out of the New York market. Some boats loaded with pea and buckwheat are afloat in the harbor, but the tonnage is not considered large. Buyers also are able to pick up reclaimed buckwheat at various prices. Some retailers continue to offer egg, stove and chestnut at around $23.50 per ton, but this supply is growing smaller.

Coke is gaining in popularity and with few exceptions retailers report a growing demand for it. Dealers are not increasing their yard supplies to any great extent. Like their customers, they are playing a waiting game and are buying according to their needs. Coke in stove and egg sizes was quoted at tidewater last week at $10@$10.50 alongside.

Pea continues to be quoted at $16@$16.50 alongside and No. 1 buckwheat at $8@$8.75 alongside.

At Philadelphia retail coal men are gradually coming back for fuel since the recent peace conferences proved abortive. Buying had been almost eliminated by the first conference and it is still comparatively dull, owing to mild weather. The price of byproduct coke has once more declined and it can now be purchased at $10 and under delivered on tracks in the city. While there is no real activity in Connellsville coke, there is an improvement over last week with prices ranging $5.50@$6.50, depending on sizing, etc.

Baltimore looks on the anthracite strike with indifference. Dealers state that prepared sizes of soft coal are accepted as substitutes without particular complaint, and that the public is apparently getting pretty well used to burning soft coal. Not a few dealers believe that many of their customers will not return to hard coal, even at prices existing last fall, as long as they can get prepared sizes of bituminous at considerably lower prices.

At Buffalo the fine sizes of anthracite are about gone. It is reported that in Canada, where more anthracite and more substitutes were bought than in Buffalo, the straight anthracite held by the dealers is about gone. There is no small amount in cellars yet, but plenty of the consumers, both here and there, will begin to run out now and they must buy something. The smokeless producers and dealers say they can meet the issue. Coke brings $12 at the curb and is not as plentiful as it was, when it used to sell as low as $9, but smokeless can be had yet for $6.50.

### Connellsville Coke Market Slightly Weaker

In the Connellsville coke market demand from the East for prepared coke has undergone little change in the past few weeks; it absorbs the tonnage offered fairly well at fair differentials above run-of-oven coke—generally from $1 to $1.50, depending on character of preparation.

Just what proportion of the total of 48-hour coke produced by merchant ovens is prepared cannot be estimated, but there is quite a tonnage left of run-of-oven coke after contract requirements have been met, and this coke has been pressing on the market for weeks, forcing prices down and down, there being approximately a 50c. decline in the past week.

This surplus coke has now also exerted a back-pressure on production, merchant-oven output last week as reported by the *Courier* being the lowest in six weeks, although the percentage in decline was small. Some ovens banked, others have been drawing less times per week.

In blast furnace sized lots coke is now available at $3.50, but by no means from all operators. Up to $3.75 probably is obtained on small lots to miscellaneous consumers. The market is quotable at $3.50@$3.75, against $4 a week ago, but then the market was decidedly weak at $4, which was largely a nominal quotation.

It is understood that blast furnaces have been offered first-quarter contracts at as low as $4.25, but apparently this does not interest them. They find little demand for pig iron, and in any event they would presumably do better to buy for January only, since whatever demand there may be from the East probably will be off for February and March.

Spot foundry coke has weakened in sympathy with furnace coke and is now quotable at $4.75@$5.25.

# Foreign Market And Export News

## British Shipments and Bookings Gain Steadily; Production on Upgrade

Increasing animation is apparent in the British coal market. The improvement has made further headway in the past week, and with steady bookings running well ahead, shipments are on an expanding scale. Chartering is brisk—an indication that activity will continue—while production is on the upgrade, with more regular work at the pits. Contractors are making early arrangements to ship the unexpired portion of yearly contracts and are showing readiness to book up to next April, beyond which points both buyers and sellers are reluctant to operate. Several parcels of second Admiralty large have been sold over the next five months, but big business on forward account is still lacking. Despite the fall in the franc, inquiries from France are improving, due to activity in the metal trades and the offering of extended credits by exporters. Italy is buying on an improved scale and the depots are active.

The prompt position in the local coal market at Newcastle-on-Tyne has been comparatively easy, and buyers with prompt tonnage have been able to obtain coals at prices much below current quotations. This has been due to the scarcity of tonnage since the bad weather set in. Forward business, however, is still indicating firm prices, and contract business shows that buyers are less averse to paying the quotations, especially for gas coals. Coking coals have enjoyed a very good demand, especially for home furnaces, and the cokes are all very firm, especially gas coke, which is better than at any time during the past year.

Output by British collieries during the week ended Nov. 28, according to a special cable to *Coal Age*, totaled 5,185,000 gross tons, compared with 4,870,000 tons in the preceding week.

## Trade Takes Quiet Turn At Hampton Roads

Comparatively little demand for coal was in evidence last week at Hampton Roads, warm weather apparently contributing to the laxity of the market. Foreign business was holding its own, but trade with New England was somewhat below normal. Domestic trade locally was holding up well, with continued high prices for prepared soft coal, and with the supply of anthracite diminishing rapidly. The tone of the market generally was quiet.

## Better Industrial and Domestic Demand in French Market

In the French coal market there has been a slight improvement in demand for industrial coals and a more active call by consumers of domestic coals.

British offers of flaming coals d.c.b. in Paris have been made at 7 fr. less than French prices, though the pound is at 124@125 fr. and over. The insistence of Belgium producers of sized coals that they be paid in Belgian francs, which arrangement was to become effective Dec. 1, will have a drastic effect on prices. Discussions between the German Kohlensyndikat and the French Government are not expected to reach a decision before the end of the year.

Deliveries of indemnity fuels from the Ruhr during the first fourteen days of November included 20,800 tons of coal, 9,100 tons of coke and 10,900 tons of lignite briquets. During the first twenty-four days of November the O. R. C. A. received from the Ruhr 166,564 tons of coke. Prices are unchanged.

## Belgian Outlook Unpromising

There is little change in the situation in the Belgian industrial coal market; demand remains moderate with stocks practically at the old level and output restricted. Prospects are not very encouraging, although the iron works of the Charleroi district probably will resume work soon.

Foreign competition is keener than ever and prices are steadily declining. The situation is most serious in the Borinage, the other districts reflecting a slightly improving tendency.

With the termination of the period of the 5 per cent increase on wages a good many coal owners seem to have made up their minds to refuse to pay it any longer, because, in spite of the measures taken by the Belgian Government, their commercial situation has not in the least improved. A complete break between the owners and their men is not expected, however, as it is likely that a new formula, based on the fluctuations of coal prices, will be considered.

No fresh development is noted as regards briquets, ovoids and coke, except an increase of stocks.

# News Items From Field and Trade

## ALABAMA

Statistics compiled by the Alabama Mining Institute indicate a total coal production for 1925 in the Alabama field of between 19,750,000 and 20,000,000 net tons. The output for the first eleven months of this year, according to these estimated figures, totaled 18,053,000 against 17,984,600 tons for the same period of last year. With a strong market now prevailing it is highly probable that the 20,000,000 figure will be reached. Output in 1924 was 19,615,931 tons. No records are kept on coke production from month to month but the output for the year probably will be around 4,750,000 tons.

## ARKANSAS

U. S. marshals have been ordered posted at the mine of the Bernice Anthracite Coal Co., near Russellville, to protect the property of the company from striking members of District No. 21, United Mine Workers, and their sympathizers. U. S. District Judge Jacob Trieber several weeks ago issued a temporary injunction restraining the strikers and their sympathizers from interfering with operation of the mines of the company, which is operating under the wage scale of 1917. One of the charges in the petition for the appointment of the federal guards was that the peace officers of Russellville have demanded $57.60 a day for their services.

## COLORADO

Wallace D. Bowie, of Delta County, has been appointed by Governor Morley as a member of the state board of examiners of coal mines, to take office at once. Mr. Bowie will serve until the third Tuesday of January, 1929, and will take the place on the board left vacant by the recent resignation of Thomas Allen.

The Kemmerer Coal Co. has been given a deed by P. J. Quealey for the property known as the International Fuel Co. and other coal lands with the exception of the Wadge vein, containing about 30 acres. The consideration was stated as $52,297. The Kemmerer Coal Co. later conveyed the property to the Uintah Improvement Co.

R. C. Graham recently leased the Black Diamond coal mine from J. J. Donnelly, owner of this coal property. This is one of the best mines in the Meeker section and has always been a big producer. Mr. Graham has complied with the new mining law requirements and the mine is now producing coal.

## ILLINOIS

Confirmation of the sale of the stock of the Southern Gem Coal Corp. was postponed in the U. S. District Court at East St. Louis, Dec. 8. Bruce A. Campbell, counsel for creditors of the company, interposed a motion asking for the continuance. Nelson Layman, of Duquoin, representing the receivers, stated that delay in confirmation of the sale might cause deterioration of the market value of the property. On Nov. 27, at Benton, W. A. Brewerton, of the Brewerton Coal Co., purchased the stock of the Southern Gem company for $100,000 cash and agreed to assume claims totaling $1,650,000.

Headquarters of the Illinois Mine Workers at Springfield announced that the Illinois convention called for March, 1926, had been postponed until March, 1927, by a vote of the membership. Only 12 locals with a membership of 1,693 members opposed the postponement; 78 locals with 30,655 members voted specific approval and 238 locals gave tacit consent by taking no action at all.

The Madison Coal Co. will electrify mine No. 6, at Auburn.

The mine commonly known as the "Scratch Back" mine, at Carterville, owned by the Carterville Black Diamond Coal Co., recently suffered a severe loss when the entire top works was destroyed by fire.

The Majestic Mine, at Duquoin, owned by the Crerar-Clinch interests of Chicago, has made a record for steady production, having worked continuously since Oct. 1.

## INDIANA

The coal mining industry in Indiana is looking better, according to Albert Dally, assistant inspector of mines and mining of the state. Four mines in the Boonville district that had been idle for more than two years have reopened recently, and two mines in the Terre Haute district have resumed.

Recognition of services rendered at the time of the Sullivan mine disaster, Feb. 20, in which 51 miners lost their lives, has been accorded the Sullivan Post of the American Legion in the shape of a lithographed citation from the National Legion organization. Legion members turned out in force at the time of the tragedy and drove ambulances, directed traffic and assisted in rescue work.

## KANSAS

No. 2 Katy mine, near South Radley, leased by James Price and Joe Lafayette from the Mayer Coal Co., is being cleaned up, and mining will start soon with from 75 to 100 men employed.

Following an explosion, Dec. 2, in the Wilbert & Schrieb mine in the southeastern Kansas field, James Sherwood, state mine inspector, issued a warning, Dec. 4, to all miners of the district to observe safety precautions more closely. The inspector found the Wilbert & Schrieb explosion was the result of using too much powder, tamped with coal drillings, and recommended the discharge of two miners. "Shots must be tamped with clay or some non-combustible material," he warned. "Mines also must be kept properly sprinkled or rock dusted and cleaned." Two entries on the south side of the mine were badly damaged, with doors and stoppings torn away. The north side of the mine, which had been rock dusted, was not disturbed. The mine reopened Dec. 7.

## KENTUCKY

Voluntary bankruptcy proceedings were filed in federal court at Louisville, Dec. 10, by the D. B. Gore Mining Co., operating a strip mine at Providence. The company's home office is in Birmingham, where its vice-president, David B. Gore, who signed the petition, resides. It lists liabilities of $127,243.70 and assets of $258,671.35. The latter include a number of so-called "dead" assets, such as insurance policies. Machinery makes up most of the assets, one stripper being listed at $103,397. The company does not own coal land, but has been operating on leases in western Kentucky for five or six years.

The Gorman-Pursiful Coal Co., Whitesburg, is planning the erection of a combined club house and hotel.

W. L. Douglass, who with John Richey, was the receiver for Jewett, Bigelow & Brooks during the settlement of the bankruptcy proceedings of that concern, stated Cincinnati Dec. 8 that payment to creditors has been held up because of legal entanglements caused by former members of the firm who advanced personal sums to the company to keep it afloat. They have entered claims for nearly $700,000 with the U. S. District Court for eastern Kentucky, which had charge of the bankruptcy proceedings. If these claims are allowed it would appear that the creditors will get only a few cents on the dollar. Until these suits are heard the money derived from the sales of the mines and other properties will be held. These amount to some $300,000.

Sixty-two employees of the Colonial Coal & Coke Co., at Prestonsburg, have joined with the executives of that concern in an arrangement which provides protection for them as a group through an insurance policy issued by the Prudential Insurance Co. Under the terms of the policy each employee who has more than one month of service will be protected for $1,000. The premiums will be paid on the contributory plan, with the workers sharing in the cost of the protection.

The three southeastern Kentucky coal associations have formulated a committee so that contact can be maintained with the American Railway Association for their concerted benefit. John Callahan of the Southern Coal & Coke Co., Cincinnati will represent the Southern Appalachian group; Prentice Burlingham, the Hazard operators, and R. C. Tway, of Louisville, the Harlan Coal Operators' Association.

The Dawson Daylight Coal Co., Dawson Springs, is now driving shaft mines in addition to its strip operations, but so far hasn't gotten the underground production up to any real loading figure. The operations are fairly well separated as to distance, but load over the same tipple.

The Stevens Branch Coal Co., of Floyd County, and J. H. Briscoe, receiver for the company, were made defendants in an involuntary bankruptcy petition filed in the U. S. District Court at Covington, Dec. 2, claims aggregating $46,682.02. It is alleged that an act of bankruptcy was committed by defendant company when while insolvent it attempted to convey to Lee Stone, of Floyd County, its entire property and assets; that it owes in excess of $100,000, and is unable to meet its obligations. The plaintiffs asked that the court discharge the receiver and order the property sold.

The Cosmos Coal Co., of which W. J. Lester is general manager, has leased the property of the Kentucky Washed Coal Co., at Nonell, a strip operation, and will soon have it in operation.

## MASSACHUSETTS

D. B. Goode, formerly of the Massachusetts Chamber of Commerce, is executive secretary of the Boston Coal Service Bureau of the Smokeless Coal Operators' Association of West Virginia. He is assisted by Henry C. Eaton, a graduate of Massachusetts Institute of Technology, as combustion engineer. They have offices in the Boston Chamber of Commerce building.

## MISSOURI

The St. Louis Coal Club gave its annual smoker and vaudeville entertainment on Dec. 14, at the American Annex Hotel. Among the out-of-town guests were Ray D. Kelly, of Springfield, Mo., and W. R. Feuquay, St. Joseph, Mo., president and commissioner of the Midwest Retail Coal Association.

**George Bryant McCormack**

Long prominent as a coal operator, industrial and financial leader in Alabama, Mr. McCormack died in Birmingham Nov. 28, of heart failure, aged 66. Born in Plattin, Mo., he removed to Birmingham in 1880 with the Tennessee Coal, Iron & Railroad Co., becoming general manager of the company in the nineties. In 1901 Mr. McCormack resigned his position with the Tennessee company and with Erskine Ramsay and other associates, organized the Pratt Coal Co. A number of other smaller operations were bought up from time to time and finally merged under the name of the Pratt Consolidated Coal Co., Mr. McCormack being president of this corporation until a few days ago, when he retired from the executive position and was succeeded by his son, Carr McCormack. The Pratt Consolidated Coal Co. expanded its operations rapidly and when merged with the Alabama By-Products Corporation in 1924 was one of the largest producers of commercial and domestic coal in the Alabama field. When the properties of the above corporations were consolidated Mr. McCormack was made chairman of the board of directors of the Alabama By-Products Corporation. He also was prominent in banking circles. He leaves a wife, four sons and two daughters.

## NEW YORK

The Buffalo City Council has passed an ordinance providing that all coal dealers shall furnish their customers with tickets stating the sort of coal delivered, together with the percentage of volatile matter in it. With the amount of smoke the city factories are allowed to belch out this regulation seems quite gratuitous.

## OHIO

One hundred and fifty miners who went back to work Dec. 11 at the Fort Pitt mine of the Central Coal Co., located at Dilles Bottom, just across the river from Moundsville, W. Va., were laid off the next day, word being received from the general office to close the mine until further notice.

The Ohio school of first-aid instruction for deputy mine inspectors ended Dec. 11 after a five-day session at Cambridge. An address was delivered by Francis Feehan, of the U. S. Bureau of Mines at Pittsburgh. He urged more accident-prevention work in Ohio mines, saying that only West Virginia has a higher fatality rate than Ohio in the Northern group of states between the Mississippi and the Alleghenies, western Pennsylvania having cut its rate to 2.91 per 1,000 miners employed, in contrast with 4.78 for Ohio and 6.56 for West Virginia.

The Essex Coal Co., of Columbus, has suspended operations at the Lost Run and Jacksonville mines, in the Hocking Valley, pending a better demand for domestic sizes. The three mines of the Stalter-Essex Coal Co. in the Pomeroy Bend field are being operated to full capacity.

Dumpings on the docks of the Hocking Valley Ry. at Toledo during the week ending Dec. 9 totaled 85,736 tons, as compared with 116,725 tons in the corresponding week last year. The total dumpings on the docks for the season were 8,387,416 tons as compared with 6,894,082 tons for the corresponding period last season. According to dock officials loading at the docks will continue for some time owing to the open winter.

Richard McGee, of Neffs, has been named deputy mine inspector for Belmont County, succeeding Thomas P. Williams, who resigned.

Mine owners in the Nelsonville field announce that more of the mines in that section are resuming operations, after an idleness of months in many cases. About 140 cars of coal are being moved from the Nelsonville field each working day.

Hatton, Brown & Co., Inc., is the name of an Ohio corporation, chartered recently with an authorized capital of $500,000 to take over all of the interests controlled by that company. The mines operated and handled under sales contracts are located in Virginia, West Virginia and Kentucky and the yearly capacity is in excess of 1,500,000 tons. The former corporation, under the same name, was a Virginia concern and acted as a holding company for the Blue Ridge Coal Co., of Virginia, and the Peerless Elkhorn Coal Co., of Kentucky. In addition the company has interests in the West Virginia field. The incorporators of the new corporation are F. G. Hatton, W. M. Brown, George F. Schwartz, C. R. Elerick and W. E. McIntire. The new company has been organized by the election of the officers of the former company, consisting of F. G. Hatton, president; W. M. Brown, vice-president and treasurer; George F. Schwartz, vice-president and secretary, and W. H. Marshall, Eastern manager. Headquarters will remain in Columbus, with a branch office in Roanoke, Va.

## PENNSYLVANIA

Edward Scott, of Scranton, has purchased from the Erie R.R. for a consideration said to be $70,000 the coal and other material used in building the old Delaware & Hudson Canal at Hawley. The purchase includes the baseball park at Hawley and the basin of the old canal. Reports have it that in 1897 a large consignment of coal was sunk in this basin and Mr. Scott is said to have made arrangements to reclaim it. There is to be a washery erected in Hawley by the new owner. Mr. Scott has been engaged in the coal business on an independent basis for several years.

The American Coke & Fuel Co. has put out sixty ovens at its American No. 2 (Sunshine) plant, at Martin, leaving eighty ovens in operation at this plant.

The Baton Coal & Coke Co., First National Bank Building, Pittsburgh, has taken over the coal mine of the Shenango Furnace Co., near Ligonier, on the Ligonier Valley R.R.

Pennsylvania Coal & Coke Corporation and subsidiaries report October net income of $4,339 after depreciation and depletion, but before federal taxes, against a deficit of $40,359 in October, 1924. Deficit for first ten months of 1925 totaled $453,194, comparing with $329,015 in same period of the previous year.

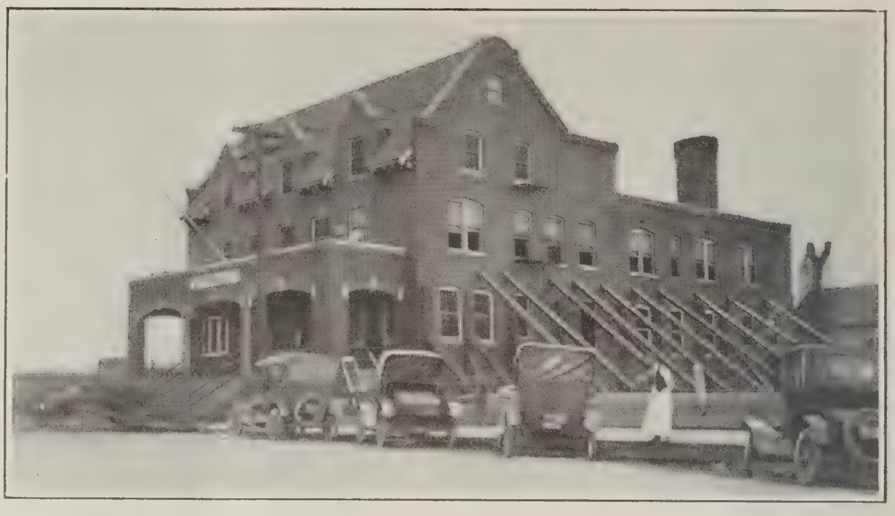
The Franklin National Bank of Philadelphia and J. A. Harris, also of Philadelphia, are seeking action against the Kennedy Coal & Coke Co. and S. H. Cauffiel, of Johnstown, in the Cambria County courts, to protect their alleged interests in the coal company property. Attorney H. S. Endsley, of Johnstown, has been agreed upon as temporary receiver for the company until a hearing on the merits of the case is had. It is claimed that calls for money have been made which threaten the minority stockholders, that the coal lands are not being developed and that all the stock has been made out to S. H. Cauffiel as trustee, who, it is alleged, is serving without bond.

The Superior Coal Co. has reopened its mine at Superior after being down for 18 months. This is in the Pittsburgh district. The Ford Colliery mine No. 3, at Curtisville, is being fitted with a new cage, and the reopening of this mine is expected. The Republic Iron & Steel Co. mine at Rural Ridge has been started on part time. All the operators in the Russellton-Curtisville district are optimistic, and miners who had left the district are returning.

Sterling Mine No. 6, at Bakerstown, has resumed operations. This is one of the big collieries in northern Cambria County and employs several hundred men.

Frank L. ("Dutch") Schwab, chosen an all-American football player twice by Walter Camp when he was at Lafayette College, has accepted a position as superintendent of the Graf Coal Co. operations at Blairsville.

A statement which will show the amount of coal mined in the city of Scranton during the year is in course of preparation by Frank B. Davenport and Frank Gaffney, Scranton City mine-cave engineers. The engineers will turn their figures over to the city board of assessors so that the tonnage removed since the first of the year can be deducted from the assessable coal land in the city in the 1926 tax duplicate. Because of the strike which halted operations on Sept. 1 the tonnage taken out this year is not expected to be as large as in normal years, although the "speeding up" policy followed in the months directly preceding the suspension will offset to a certain extent the production decrease.



**Oklahoma Coal Mine Causes Y. M. C. A. Building to Topple**

The use of heavy planks has been necessary to prevent the collapse of the Railroad Men's Y. M. C. A. building, at Haileyville, Okla. The old Hailey-Ola coal mine, which underlies the townsite of Haileyville, is believed to have caused the earth to sink. The mine was abandoned years ago and the company is now working an extension of the same coal seam several miles southwest of the original workings. The building was abandoned early this year, when large cracks were discovered in the walls and the cause revealed.

The Irwin Gas Coal Co., of Greensburg, has contracted with the Roberts & Schaefer Co., Chicago, for a quick-return oscillating - screen equipped tipple.

R. B. Hays Coal Co., of Masontown, has contracted with the Roberts & Schaefer Co. for the installation of coal conveying and quick-return oscillating screen equipment for its No. 2 Mine at Uniontown.

Dr. W. Frank Beck, one of central Pennsylvania's foremost coal operators, has entered the race for the Republican nomination for State Senator from the district composed of Blair and Huntingdon counties. He will be opposed by the present incumbent, Plymouth W. Snyder. Dr. Beck is a resident of Lakemont, a suburb of Altoona. He is president of the Priscilla Coal & Coke Co. and secretary-treasurer of the Jefferson Ridge, Campbell Ridge and the Thomas Mills Coal companies. Dr. Beck formerly was a practicing physician and is prominently identified with the Grange, having farming interests as well as coal interests.

The Trumbull Coal Co., of Cleveland, has contracted with the Roberts & Schaefer Co. for conveying and quick-return oscillating screen equipment for its tipple at Clarksville.

The Pittsburgh Coal Co. has resigned from membership in the Pittsburgh Coal Producers' Association, assigning as a reason "the general condition of the coal situation." Its operation of five mines on the November, 1917, scale would not necessitate its withdrawal. It is said that the company will continue to support the movement for a lower Pittsburgh district rate on lake coal and that some members of the association have been unwilling to support that program.

The H. C. Frick Coke Co. is still adding ovens to its active list, having fired 400 more at different plants last week.

With the recent opening of the Conifer mine of the Allegheny River Coal Co., better known as the Pittsburgh & Shawmut Coal Co., from its sales auxiliary, all the mines of this company are working again at some rate.

The Pittsburgh Terminal Coal Co., Pittsburgh, has contracted with the Roberts & Schaefer Co. for the construction of local trade bins at its Castle Shannon mine.

Shipments of bituminous coal by the Reading Company during October, 1925, totaled 1,867,412 gross tons, compared with 1,617,084 tons in the corresponding month of 1924.

## UTAH

R. M. Magraw, former general superintendent for the United States Fuel Co., has been appointed to a similar position with the Brady-Warner Coal Corp. of West Virginia, with headquarters in Fairmont. Mr. Magraw came West in 1905 after beginning his career in West Virginia.

The Utah Industrial Commission has handed down a ruling that a laborer engaged in unloading coal from a railroad car under the form of contract adopted for this work by coal dealers in Salt Lake City is not an employee of a coal company within the meaning of the state workmen's compensation law. He in an independent contractor. It was pointed out that under the contract which the companies have adopted the man unloading the coal can engage help if he desires and is not himself under the control of the coal company so long as he completes the contract on time.

### VIRGINIA

The Clinchfield Coal Corporation has declared a dividend of 50c. on the common stock of the company, bringing total payments for 1925 on the common stock up to $3 per share.

Coal output in the Virginia field recently has reached 243,884 tons a week, but of a total of 153 railroad tipple mines in the field, 81 are active and 72 idle. Many of the idle mines, however, are small. Production of coke has materially increased but is still considerably behind that of 1923 and 1924.

### WEST VIRGINIA

The Paisley interests have obtained a lease on the Benwood mine of the Wheeling Steel Corporation and propose to improve and extend its facilities until the present capacity is doubled. This property includes 5,000 acres of good coal land. The contract for the steel corporation calls for delivery at the rate of 200,000 tons per year for the use of the Benwood mills. It is expected that a like tonnage will be marketed elsewhere via rail and river. The large expansion of this property, both in the opening of new shafts and the installation of improved machinery, probably will make the mine the largest single producing unit working the Pittsburgh No. 8 seam.

Federal mine No. 1 of the New England Fuel & Transportation Co. is about one-third rock-dusted. About eight miles of haulageways, aircourses, etc., are so treated. It is planned to complete the work by Feb. 1. This is one of the largest mines in the region.

In opening a new mine at Skelton and establishing a plant at that point, the Elkhorn Piney Coal Mining Co. has let a contract for the construction of a large tipple costing about $150,000 to the Link Belt Co. It is expected to make this plant among the largest producers in the smokeless field. It will have a daily output of 2,000 tons of prepared sizes of low-volatile coal. One hundred houses and the necessary office and other buildings are also to be constructed at an outlay of approximately $100,000. Coal will be mined in the Sewell seam, which is about 4 ft. thick at the point where it will be mined. Nut, egg, lump and slack will be produced. The Elkhorn Piney company now operates three mines at Stanaford. Its officers are J. W. Shaeffer, president; Lou Roach, general manager; J. W. Ailstock, general superintendent.

The plant of the West Williamson Coal Co., which has been idle for some time, has been leased by H. T. Williamson to James and Oscar North, well known coal operators and dealers of Portsmouth, Ohio. Work of cleaning up the mine and making necessary repairs to equipment was begun on Nov. 30. Coal is to be mined from the Thacker seam.

W. W. Brewer, of Belington, has been made superintendent of the Chesapeake mine of the Fairmont-Chicago Coal Co., at Barrackville.

A certificate has been issued by the Secretary of State of West Virginia for a reorganization and decrease in the capital stock of the Elk Horn Coal Corporation. Capitalization has been decreased from $28,600,000 to $6,600,000.

**Has Coal Mine in His Yard; Not Worried by Strike**

Charles B. Zimmerman, a Shamokin (Pa.) merchant, is not particularly upset about the anthracite strike, having struck a good seam of hard coal in his back yard, which will take care of his fuel needs for a while, as he owns the mineral rights under his lot. Mr. Zimmerman is at the right of the group, seeming to be more interested in the coal than the camera.

The Pocahontas Fuel Co. plans to have its large tipple at the new Faraday plant in operation soon. The company has been rushing the steel and cement work. Unofficially it is learned that as many as 50 to 75 cars of coal can be dumped over the tipple in a single day, when the work is completed. Though the tipple is uncompleted, the company is mining coal. About 700 men are now on the payroll at Faraday, part of the force being engaged in building more homes for the miners. This is said to be the biggest mining project ever launched in southern West Virginia.

A rope and button conveyor 825 ft. long will be erected late in January at the mine of the Vera-Pocahontas Coal Co. along the N. & W. Ry. at Iseger, McDowell County, by the Fairmont Mining Machinery Co. The conveyor will carry coal from the top of the mountain to the railroad below.

Announcement has been made by West Virginia University that the short course in coal mining will be held in Mechanical Hall, Morgantown, from June 14 to July 24, inclusive.

Kenna mine of the Clark Coal & Coke Co. resumed operation on a non-union basis in Tunnelton last week.

The Consolidation Coal Co. has completed arrangements to purchase from the West Fork Coal Co. the Central mine, in the vicinity of Monongah. The consideration is understood to have been $10,000. B. F. Evans is president of the West Fork Coal Co.

The Algoma Coal & Coke Co., of Algoma, has contracted with the Roberts & Schafer Co. for a complete Marcus tipple and dry cleaning plant, which will embody the use of the Arms screens and concentrating tables. The plant will be complete with "RandS" shaker loading booms and will make all of the prepared sizes of Pocahontas coal.

M. H. Hall has been appointed general superintendent of the Bartley "wireless" mine of the Pond Creek Pocahontas Co., vice H. C. McKalip, resigned. Mr. Hall formerly was chief engineer of the Pocahontas-New River Division of the Consolidation Coal Co., Coalwood.

H. E. Spernon, H. A. Ambrose, J. T. Hite, F. M. Lynch, all of Ohio, and Stephen Mason, of Fairview, have purchased 1,172 acres of Pittsburgh coal in the Grant district of Wetzel County. Although the consideration was not disclosed, it is understood on good authority that the price paid was around $50,000. The understanding is that a Pittsburgh concern is negotiating for the purchase of this valuable block of coal with a view to developing it for operation in the near future.

Operations were resumed Dec. 11 with 200 employees at the Richland and McKinleyville mines, owned by the J. C. McKinley interests. Financial difficulties last August forced this mine to discontinue operations, and a sheriff's sale for taxes was averted by a receivership. These matters have since been adjusted. A third mine owned by the company in Marshall County reopened Dec. 14 after being taken over by the Hitchman Coal Co. This mine employs 150 men.

Answering a contempt citation in Circuit Court last week, C. M. Workman, a member of the Executive Board of District 17, United Mine Workers, charged the international organization of the miners with practically destroying the union in West Virginia. Workman had refused to sign a deed turning over district union property to the international organization after the mother union had suspended the autonomy of the district. The court had authorized the board members to make the deed, and Workman, refusing to sign, was charged with contempt.

### WYOMING

H. C. Marchant, general manager of the Rock Springs-Superior Coal Co., has resigned his post with that company to accept a position with the P. J. Quealey coal interests as assistant to President Quealey. He will spend the next few months in Denver, after which he will establish his headquarters at Kemmerer, head offices of the Quealey interests.

### CANADA

In the Criminal Court in Calgary on Dec. 4 five miners convicted of unlawful assembly to compel others to abstain from working in the A B C coal mine at Drumheller last summer were sentenced to one year's imprisonment. Five others convicted on a charge of watching and besetting the mine were sentenced to two months imprisonment.

The Nova Scotia Coal Commission concluded its sittings in Sydney on Dec. 3. The commission has gone to Montreal, arranging to return to Nova Scotia in a few days, when the hearing of evidence will be resumed at Halifax. The chairman stated that he hoped to deliver the findings of the Commission before the end of the month.

The output of coal during November from the mines of the British Empire Steel Corporation totaled 455,000 tons, an average of more than 18,000 tons per day.

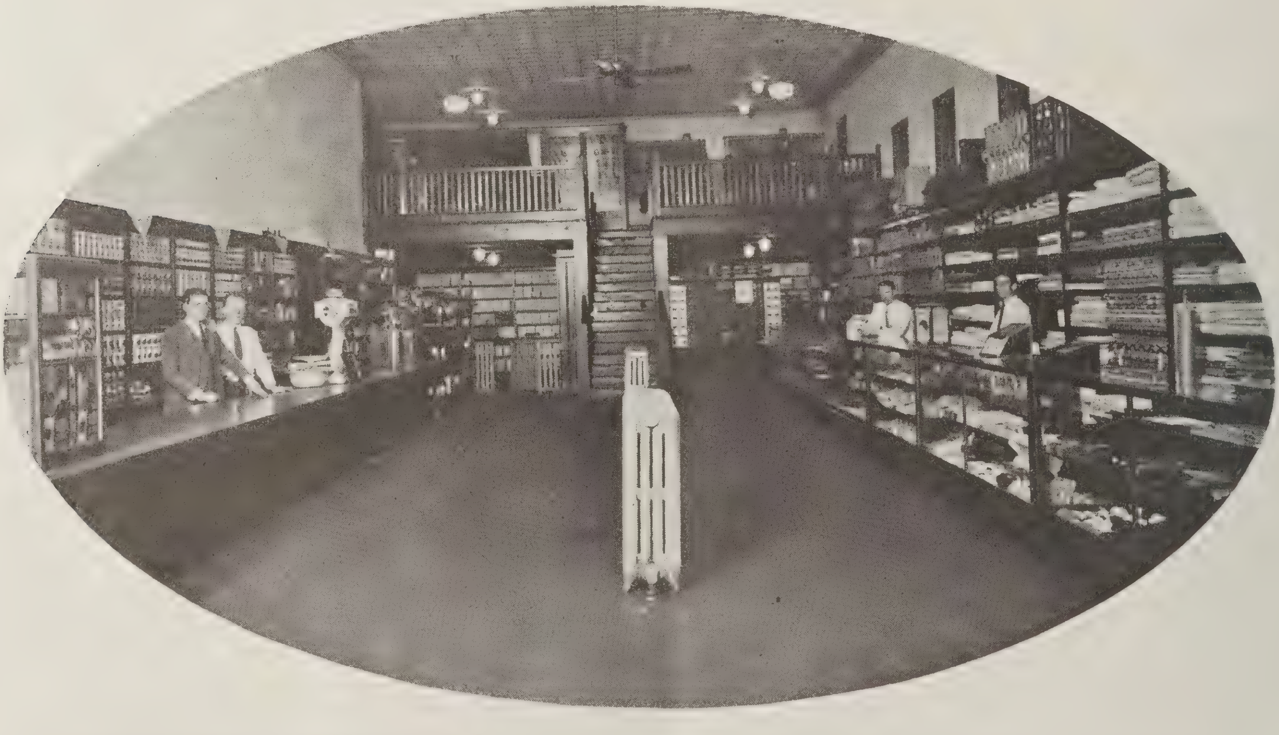
Output of coal from Canadian mines during September was 1,191,081 tons, as against 988,824 tons in August, and an average for the month during the five preceding years of 1,312,448 tons. Production in September showed a considerable gain over August in Nova Scotia and Saskatchewan, but slightly lower figures for Alberta, British Columbia and New Brunswick than in the preceding month. Saskatchewan and Nova Scotia were the only provinces which reported a greater output in September than the average for the month in the five preceding years. Imports of coal from the United States and Great Britain in September totaled 1,872,417 tons as compared with 2,177,270 tons in August and the five-year average of 1,660,712 tons.

Production of coke in Canada during October totaled 161,414 tons, an increase of 57 per cent over the 102,882 tons produced in September. The amount of Canadian coal used for coke making rose to 84,390 tons from 48,468 tons in September, and imported coal advanced to 163,060 tons from 109,015 tons in the same time, bringing the total consumption of coal for coke making to 248,060 tons as compared with 157,483 tons in September. Imports of coke in October were 94,213 tons as compared with 78,732 tons in September, while exports were 4,149 tons as compared with 4,268.

## Obituary

**Dr. C. B. Lee**, 58, of Glen Jean, W. Va., died suddenly Dec. 3, in Philadelphia, where he had gone to see his wife, who was in a hospital. Funeral services at Charleston, W. Va., on Dec. 7, were conducted by Bishop W. L. Gravett. Dr. Lee, who was president of several mining companies in the Loop Creek section of Fayette County, had been prominent for a number of years in the smokeless coal industry of southern West Virginia. He was associated in business with William McKell, Thomas Nichol, Dr. Gory Hogg and other well-known coal leaders of the state.

**Edwin O. Parkinson**, district manager of the Pocahontas Fuel Co. at Norfolk since the firm's organization 16 years ago, died in New York, Dec. 6, after an illness of two years. Prior to his connection with the coal company he was agent for the Norfolk & Western Ry. He was prominent in business and civic affairs in Norfolk, being a director of the Hampton Roads Maritime Exchange, a director of the Norfolk National Bank, and otherwise prominently identified with business and civic interests.



**An Up-to-Date Commissary of a Coal Mining Company in the Harlan Field of Kentucky**

This company store is located at Alva, Harlan County, Ky., and supplies the needs of the coal mining community of the Black Star Coal Co. As can be seen in the illustration, the store is planned with plenty of floor space which affords a good display of provisions and merchandise. The commissary is well lighted and the ceiling fan and radiator would indicate that the company when erecting this store kept in mind the comfort of its employees who work and trade here.

## Coming Meetings

**Chicago Wholesale Coal Shippers' Association.** Annual meeting, Great Northern Hotel, Chicago, Ill., Jan. 6, 1926. Secretary, G. H. Merryweather, Temple Bldg., Chicago, Ill.

**American Wood Preservers' Association.** Annual meeting, Jan. 26-28, 1926, at Cleveland, Ohio. Secretary, E. J. Stocking, Chicago, Ill.

**Coal Club of Philadelphia.** Annual meeting, Jan. 28, 1926, at the Bellevue-Stratford Hotel, Philadelphia, Pa. Secretary, C. K. Scull, Philadelphia, Pa.

**Northeast Kentucky Coal Association.** Annual meeting, Jan. 28, 1926, at Ventura Hotel, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

**American Institute of Electrical Engineers.** Annual convention, Feb. 8-12, 1926, at Engineering Societies Bldg., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

**The Rocky Mountain Mining Institute.** Winter meeting, Feb. 23-25, 1926, at Albany Hotel, Denver, Colo. Secretary, Benedict Shubart, Boston Building, Denver, Colo.

## New Companies

**The Grounds Coal Corporation** has been incorporated at Dana, Ind., with 500 shares of no par value capital stock. The company will do a general mining business. The incorporators are Curtis Grounds, Lee Grounds and Wesley S. Harris.

**The Boone County Mining Co.** has been incorporated in Columbia, Mo. by H. H. Hebenstreit, Melvin E. Hebenstreit and others.

**The Northend Coal Co.** was recently chartered in Henrietta, Okla., with a capital stock of $10,000, by Ira Exley, R. R. Fretwell and others.

**The Zenith Briquet & Mines Corporation,** of Minneapolis, Minn., has published articles of incorporation, with a capital stock of $100,000. The incorporators are Hanson Evesmith and Ruggles Evesmith, both of Minneapolis, and Mary Wilson Evesmith, of Fargo, N. D. The purpose of the corporation is described as owning and working mineral lands and manufacturing and marketing the products.

**The Blue Jacket Coal Co.,** Covington, Ky., has been incorporated by M. H. McDean, T. J. Bell and Edward Engelkamp.

**The Copley Utilities, Inc.,** 72 Fox Street, Aurora, Ill., was recently incorporated; capital $10,000 and 183,750 shares of no par value. The company will operate coal mines and distribute natural gas. The following are the incorporators: C. A. Huebner, G. T. Johnson and B. P. Alschuler.

## Industrial Notes

**C. F. Phillips** has been appointed representative in charge of Wilkes-Barre (Pa.) office of the Allis-Chalmers Mfg. Co. Mr. Phillips, who formerly was connected with the Philadelphia office of the company, succeeds Guy V. Woody.

**Herbert E. Smith,** general sales manager of the United States Rubber Co., has been elected a second vice-president of the company in general charge of sales activities of all commodities except tires, succeeding George H. Mayo, retired.

## Recent Patents

**Mine Post;** 1,555,053. John T. Youger, Carmichaels, Pa. Sept. 29, 1925. Filed Nov. 26, 1923; serial No. 677,071.

**Synchronized Rotary Dump;** 1,555,077. Erskine Ramsay, Birmingham, Ala. Sept. 29, 1925. Filed Dec. 15, 1924; serial No. 680,935.

**Attachment for Mining Machines;** 1,555,464. Wm. H. Farne, Williamson, W. Va. Sept. 29, 1925. Filed Nov. 28, 1924; serial No. 752,654.

# New Equipment

## Joy Loading Machine Design Shows Some Improvements

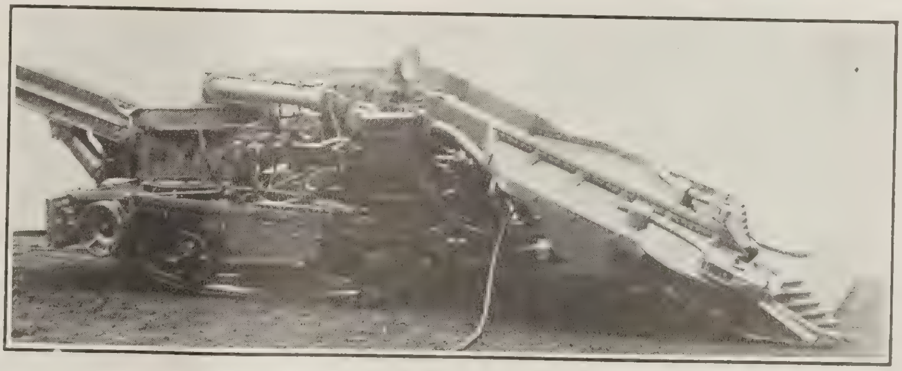
Through continual field experience the Joy Machine Co. recently has improved several details of construction in its loading machine. Thus, in order to obtain an increased capacity, the size and shape of gathering arms have been changed to give a solid manganese steel part with cutting points cast integral therewith instead of the bits employed on the old style of arm. These manganese steel points maintain their sharpness over a considerable length of time without attention, and the danger of losing cutter bits formerly experienced has been entirely eliminated.

Design of the caterpillar sprocket rollers also has been changed from a built-up type, consisting of one inner and one outer half with a plate sprocket bolted between them, to a solid steel roller so designed that accumulations from the caterpillar chain can escape through an opening provided for that purpose. The new design of roller will last almost indefinitely. Solid cast track wheels also have replaced the built-up type formerly used, thus eliminating maintenance expense on this machine part.

As formerly designed, the caterpillar chains operated over two center rollers on each side of the machine. These have now been replaced by a steel supporting shoe giving greater bearing area for the caterpillar chain, thus obviating the buckling and breakage of chains experienced with the former rollers. By this new device, practically all caterpillar chain breakage has been eliminated and the life of these chains has been increased approximately 100 per cent.

In order to obtain a more dependable hydraulic pressure in the system actuating the vertical movement of the gathering head as well as that of the rear conveyor, a new control valve has been designed. This controls all these actions through one mechanism. The new valve is provided with renewable seats and maintenance or replacement costs, consequently, are greatly decreased.

To decrease maintenance costs and improve operation of the pump supplying hydraulic pressure, a ball-bearing drive has been substituted for the former bronze bushing used at this point. Several other details embodied in the machine have been appreciably strengthened through redesign. Field tests extending over several months have proved that the output of the machine has been increased and its maintenance expense reduced by these improvements.



**Several Details Have Been Improved**

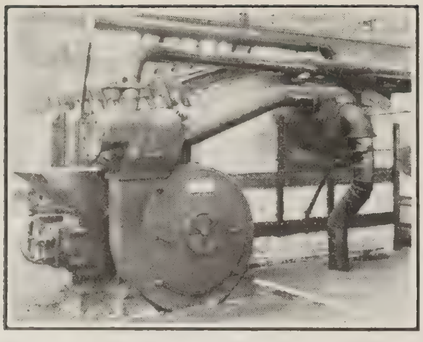
Particularly noticable in this side view are the new gathering arms and the shoe supporting the caterpillar chain. The arms are one-piece castings of manganese steel with integral points displacing the pick points of the former design. The chain-supporting shoe eliminates buckling of the chain and affords a larger bearing area.

## Small-Size Pneumatic Stoker Pulverizes and Fires

What is known as the Vulcan pneumatic stoker, a coal pulverizing and firing outfit of small size, recently has been placed on the market by A. A. Wickland & Co., of Chicago, Ill. Machines of this kind have now been in operation for slightly over a year and both the pulverizing unit and burner have proved their efficiency in the operation of both steam boilers and reverberatory furnaces.

Advantages claimed for this outfit by the manufacturer include the following: Low initial cost, simplicity, rugged construction, positive mechanical feed, accessibility, low expense for the replacement of wearing parts, three-stage pulverization and a means for positive separation of metal, stone, slate and other heavy materials from the fuel. This machine will pulverize screenings to a fineness of 85 per cent through 200 mesh. The actual fineness of the product depends somewhat upon the structure and dryness of the coal employed. The burner furnished with the pulverizer is designed to produce a thorough mechanical mixture of the powdered fuel and air. This mixture enters the furnace at a low velocity and is held in suspension by the introduction of secondary air through ports within the furnace.

Installations of this stoker have been



**Pulverizes Coal and Delivers Direct**

Pulverization takes place only as needed. From the pulverizer the fuel is delivered by an air blast through a short pipe to the furnace. The grinding and delivery equipment may be placed either in front or at the side of the furnace, thus offering a choice of positions. This is a highly advantageous feature in the power plant, particularly if room is at a premium.

made to serve an open hearth furnace, reverberatory furnaces and for operating boilers. The pulverizer has a rated capacity of 2,500 lb. per hour and requires about 19 kw. of electric energy per ton of coal treated per hour. The powdered product is withdrawn from the pulverizer by an air draft and fed almost directly into the furnace. The equipment may, however, be installed either in front of the boiler furnace or at one side, thus giving an excellent choice of location for this machinery within the power plant.

## Eliminates Much Labor On the Job

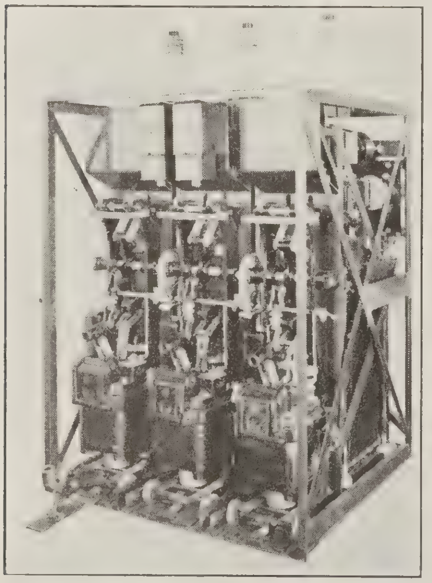
A housing framework for Type FK-54 oil circuit breakers is now being manufactured by the General Electric Co. It is designed primarily to meet the demand for equipment which can be installed with a minimum of skilled labor.

The three runways of the framework are welded into one solid piece, forming a base plate to which is welded an overhead structure of angles and steel straps. Though the design is simple the framework is of sufficient strength to hold bushings, contacts and runways in permanent alignment. To install the equipment it is merely necessary to run the housing into the cell, secure it with grouting through the base plate and make the usual connections.

The units are securely interlocked to prevent withdrawal of closed breakers, and there is a positive interlock between tripping coils so that the opening of one unit opens the entire circuit. A grounding device on each breaker, consisting of a long blade on the housing which engages a spring clip on the unit, gives grounding protection until the main contacts have been separated 3 in.

All single-pole units can be assembled singly or in two-, three-, or four-pole groups. At 7,500 volts, the ampere capacities are 400, 600, 800, 1,200, 1,600 and 2,000 amp. The interrupting capacity is 10,500 amp. at 7,500 volts for two-, three-, or four-pole operation.

Another advantage of this new housing framework is the ease with which the three top bushings can be located, all time-consuming adjusting being eliminated. The bushings are so arranged that contacts are in perfect alignment. Although these bushings are removed for shipping and cannot be replaced until the housing is in its cell, a system of numbers and dowels enables the user to replace the bushings in the same alignment obtained at the factory. Mounting plates are not interchangeable. Rear bushings are shipped to the customer mounted in position.



**Simple Mounting for Solenoid-Operated Breaker**

Separate single-pole units can be arranged in groups to make two-, three,- or four-pole switches. The framework is easy to handle and can be quickly set in position.

## Publications Received

**A Thermodynamic Analysis of Gas-Engine Tests,** by Crandall Z. Rosecrans and George T. Felbeck. Engineering Experiment Station, University of Illinois, Urbana, Ill. Bulletin 150. Pp. 98; 6x9 in.; illustrated. The object of the investigation leading to the publication of this bulletin was to apply a rational thermodynamic analysis of the constant-volume, or Otto, cycle to test results obtained from an engine operating on such a cycle.

**Coal Losses in Illinois,** by C. A. Allen. Illinois Mining Investigations prepared by the U. S. Bureau of Mines, with the collaboration of the Illinois Geological Survey and the Engineering Experiment Station of the University of Illinois, Urbana, Ill. Bulletin 30. Pp. 36; 6x9 in.; illustrated.

**Coal Resources of District III** (Western Illinois, by Harold E. Culver. Illinois mining investigations prepared under a co-operative agreement between the Illinois State Geological Survey Division, The Engineering Experiment Station of the University of Illinois and the U. S. Bureau of Mines. Bulletin 29. Pp. 128; 6x9 in.; illustrated.

**Coal,** by Edward T. Devine. American Review Service Press, Bloomington, Ill. Pp. 448, 5 x 7½ in.; illustrated. Covers the economic problems of the mining, marketing and consumption of anthracite and soft coal in the United States.

**The Mineral Resources of the Philippine Islands for the Years 1921, 1922 and 1923.** Division of Geology and Mines, Bureau of Science, Manila, P. I. Pp. 63; 7½ x 10½ in.; tables.

**Electrical Exploders for Shot-Firing in Coal Mines.** Safety in Mines Research Board Paper No. 11, H. M. Stationery Office, Kingsway, London, England. Price, 1s. net. A report of a sub-committee of the Explosives in Mines Research Committee. Pp. 31; 6 x 9½ in.; illustrated.

**Coke-Oven Accidents in the United States During the Calendar Year 1924,** by William W. Adams, Bureau of Mines, Washington, D. C. Technical Paper 388. Pp. 38; 6 x 9 in.; tables.

**Misuse of Flame Safety Lamps and Dangers of Mixed Lights,** by L. C. Ilsley, Bureau of Mines, Washington, D. C. Miners' Circular 29. Pp. 12; 6 x 9 in.; illustrated. Price 10c. Describes how explosives have been caused by the abuse or misuse of flame safety lamps or by the use of open lights and safety lamps in the same mine.

## Trade Literature

**"Turbinair" Portable Hoists.** Sullivan Machinery Co., Chicago, Ill. Bulletin No. 76-F. Pp. 15; 6 x 9 in.; illustrated. Describes types HA-3 and HA-2 single drum and type HDA-2 double drum.

**Dimension and Load Bulletin No. 1559.** Hyatt Roller Bearing Co., Newark, N. J. Pp. 13; 8½ x 11 in.; illustrated.

**Raw Water Distilling Plants for Producing Distilled Boiler Feed Make-Up Water.** The Griscom-Russell Co., 90 West St., New York City. Pp. 39; 6 x 9 in.; illustrated. Fifth edition. Covers the latest developments in evaporator plants for purification of boiler feed make-up.

**Construction of Parallel Wire Cables for Suspension Bridges.** John A. Roebling's Sons Co., Trenton, N. J. Pp. 94; 9 x 12 in.; illustrated. Describes and illustrates the construction of a modern suspension bridge and contains latest data in connection with the fabrication of bridge cables.

General Electric Co., Schenectady, N. Y., recently issued the following: Bulletin GEA-133, illustrating the G-E **electrically operated flow meters for measuring steam, water, oil, gas, etc.** Bulletin GEA-235, describing and illustrating the general principles and advantages of **Steam Turbines;** sections and steam path diagrams are shown. GEA-178, on **Instrument Transformers,** containing 52 pp. devoted to the theory and engineering characteristics of transformers used to facilitate the measurement of electrical qualities; the book is well illustrated with photographs, diagrams, charts and tables.

**Comparison of Diesel Engine Principles.** Fairbanks, Morse & Co., Chicago, Ill. Bulletin No. 1020. Pp. 32; 8½ x 11 in.; illustrated. Analyzes and interprets the various factors which influence the design of Diesel engines.

**Splices and Tapes for Rubber Insulated Wires.** The Okonite Co., Passaic, N. J. Pp. 15; 6 x 9 in.; illustrated. Describes the importance of a perfect splice, properties of tape, how to recognize these properties and how to make a perfect splice.

The **"Burden Bearers"** is the title of a booklet published by Standard Steel & Bearings, Inc., Plainville, Conn. It describes the forging of molybdenum steel balls and tells how these balls can be produced with required accuracy and yet be capable of carrying heavy loads for long periods of time.

The Climax Engineering Co., Clinton, Iowa, has issued a series of bulletins covering its various models of **engines.** Bulletin A describes the "K" series, four-cylinder, 5 x 6½-in. engine. Bulletin B covers the "T" series, four-cylinder, 5½ x 7-in. engine. Bulletin C describes the "R" series, which is made in two models—model "R4U," covering the four-cylinder 6 x 7-in. engine, and model "R6U," covering the six-cylinder 6 x 7-in. engine. Bulletin D covers the "K" and "T" series portable power houses. These bulletins are all illustrated and measure 8½ x 11 in.

The Allis-Chalmers Co., Milwaukee, Wis., has issued Leaflet No. 2082, on **Centrifugal Boiler Feed Pumps.** It contains 7 pp., is 7¾ x 10½ in., illustrated.

Electric Service Supplies Co., Philadelphia, Pa., has issued Bulletin No. 216, on **Floodlighting.** The bulletin is well illustrated and includes charts and diagrams.

**Blasting Accessories** is the title of a booklet of 80 pp. issued by E. I. du Pont de Nemours & Co., Wilmington, Del. It gives complete and detailed data on the various accessories needed for firing charges of explosives, with explanations of the best methods of using these accessories.

American Blower Co., Detroit, Mich., has issued the following two bulletins: **Type "D" Mine Fans,** Bulletin No. 3313, and **"Sirocco" Air Washers,** Bulletin No. 1923, describing the manufacture, operation and use of these washers.

# COAL AGE

McGRAW-HILL COMPANY, INC.
JAMES H. McGRAW, *President*
E. J. MEHREN, *Vice-President*

Devoted to the Operating, Technical and Business Problems of the Coal-Mining Industry

R. DAWSON HALL
*Engineering Editor*

Volume 28 NEW YORK, DECEMBER 24, 1925 Number 26

## What the Public Wants

BECAUSE the anthracite producers have declined to have anything to do with the Pinchot eleven-point "peace" program, the Governor of Pennsylvania charges them with warring against the public. That the public is a real party to the controversy between the operators and the miners is well recognized. But before we can acknowledge any truth in the Pinchotian indictment, we must understand clearly what the objectives of the public are and how they coincide or conflict with the objectives for which producers and miners have been fighting since July.

What does the public want? First and foremost, the public wants an uninterrupted supply of coal. It wants the old-time assurance that coal can be had whenever the consumer is disposed to order fuel. Second, the public wants to purchase that coal at the lowest possible price. If the issue is raised, the public is willing that that price shall be high enough to fairly compensate both the capital and the labor employed in the production and distribution of coal. These are the sum total of its wants.

The public has complained in recent years that these simple wants have not been met. The anthracite producers have conceded that there is merit in that complaint. To meet the first demand of the public they have asked repeatedly that the miners join with them in an agreement which would make future strikes impossible. The basis of that proposed agreement is that disputes between employers and employees which cannot be settled by direct negotiations shall be submitted to an impartial board of arbitration.

To meet the second demand of the public, the operators have declared their opposition to further increases in the cost of production. The union, in terminating the wage negotiations with the producers at Atlantic City last summer, refused to give the employers the opportunity to present the grounds for their opposition to further increases in labor costs. The union scale committee disputed the claim that the industry could not pay higher wages without passing on the cost to the consumer and then denied the operators a hearing on that claim.

Union leaders and Governor Pinchot have accused the operators of declining "to yield one jot or tittle of their original position." That accusation, however, conveniently ignores the fact that the operators have offered to submit their justification to the judgment of an impartial board of arbitration with unrestricted power to determine the issues. The greatest concession that the union leaders have been willing to make in the public interest is an agreement to submit to arbitration *how much higher*, if any, wages might be advanced. Arbitration to prevent future suspensions has been repeatedly rejected by Mr. Lewis and his associates.

The public wants an assured supply of fuel at a fair price. The public wants are the operators' necessities. For insisting upon meeting those wants, Mr. Lewis and Governor Pinchot charge the operators with warring against the public.

## On Solid Ground

RUMOR HAS IT that the British visitors who have just departed were principally impressed in their trips through the mines of this country, not so much with our mechanical developments as with our practice of keeping our haulage roads in solid coal instead of in the "goaf or broken" as they would term it. The British use much longwall advancing and so have roads that lack permanency, with crumbling roofs and moving sides. The investigations of the visiting party seemed to convince them that longwall retreating was better because it afforded good roofs and a reduction of timbering.

In some cases where permanence is desired, as in the anthracite region where thick beds are mined under heavy cover, gangways in the rock or in underlying coal beds too thin to mine and where rock has to be lifted or brushed have been used with success. They frequently have in a high degree the permanence that is so desirable. Timber is not needed, or may be used sparingly.

The gangways are truly "in the solid," and nowadays with machines so readily available for loading rock it is to be expected that the mileage of such gangways will be greatly increased, especially for drainage purposes. Many a mine manager if he could have foreseen the timber costs, delays, danger and maintenance expense that his gangways in the coal entailed would have cheerfully faced the expense of placing them in solid strata where they would have been subject to less strain from mining operations. In fact, the elaborate timbering in some of the workings suggests forcibly that tunnels in the rock might frequently be made to replace present gangways with improvement in some cases in the gradients of the roadway.

## Fewer Types of Equipment and Fewer Troubles

"I'D CERTAINLY like, sometime, to work where all the equipment is the same," said the chief electrician of a large mine. After a pause he added, "But then, you don't get paid for doing nothing. The chief at a standardized mine would have a snap, and more than likely would be paid accordingly." He was not, necessarily, correct in his conclusion that standardization of equipment would mean that the company would make a saving by paying a lower salary to its chief electrician. Such men are paid for their knowledge and for being on the job ready for emergencies, instead of for the actual physical and mental work performed. Nevertheless, this chief electrician correctly judged the importance of standardization.

One evident and direct advantage of standards is the reduced stock of repair and spare parts necessary to insure continuous operation. Less space and less labor are required to store and maintain the stock, and it is more certain that necessary parts are on hand when the call comes. Fewer repair men are needed, and better work is done because the men are more familiar with the details of the equipment. Cases of abuse by machine operators to one type of machine, in order to get the chance to use a preferred type, are eliminated; a less percentage of delay makes it possible to operate with fewer machines; mechanical troubles are more readily detected, and permanent improvements thereby effected. Investigation usually will reveal that, at low-cost mines, highly standardized equipment and methods are in use.

## An After-the-War Readjustment

BECAUSE of the cheapening of money and the appreciation of goods, salaries have in general been raised throughout the United States, but not adequately in the government service, though increases have been granted to those whose emoluments are commonly known rather as wages than as salaries.

Justice demands that the compensations of those in the government service shall rise and fall reasonably in accord with the salaries and wages of the public in general. It must be remembered that none of them has a way of supplementing his earnings like Congressmen by performing unofficial service.

Just at present pressure is being brought to raise the salaries of district judges 33 per cent from $7,500 a year to a minimum of $10,000 with a maximum set $1,000 below the salary of circuit judges wherever the district population exceeds 2,000,000. The circuit judges, who have been receiving $8,500, would have their salaries increased so as to range from $3,000 to $15,000. The Supreme Court judges will be raised from $14,500 to $20,000 and the Chief Justice from $15,000 to $20,500.

Since 1891 the salaries of district judges have been raised 50 per cent, of circuit judges 38½ per cent and judges of the Supreme Court 16 per cent. The salary of the chief justice is less than a third that of Great Britain's leading judicial authority and half that of Ireland's principal judge. The Lord Chief Justice of Scotland gets two-thirds more than our Chief Justice and the rate in India is but $1,000 less.

That is not all. The salaries for state judges are lower than the salaries for federal judges in a large number of cases. A judge of the Supreme Court of Pennsylvania or New York gets $3,000 a year more than a judge in the Supreme Court of the United States, yet it is now proposed to raise these salaries in the first-named state. The proposed bill will add only $743,000 to the national budget, and the total cost for all the salaries of all the federal judges in the United States will be less than two cents per year for every person in the United States.

No less than six judges in the New York district have recently resigned to enter legal practice which nets them much larger returns. The president has found others to replace them, doubtless, but the character of the judges must decline if their present salaries are to continue; first, because the best men will not enter the service of the government, and second, because they will leave before they become definitely posted on all the matters which a judge must decide.

## Progress of the Strike

EVIDENTLY the boys are not to be out of the trenches by Christmas, although it is rumored here and there that peace in the matter of the coal strike may not be far off. The main strategy of the Mine Workers, upon which their officials depended, has so far failed, in the lack of enthusiastic response of public sentiment in their favor and the expected amount of clamor and pressure upon the government to intervene.

And the government at Washington persistently refuses to jump when the strings are pulled by the officials of the striking coal union. Wages in the anthracite industry, they recognize, and the public recognizes, are already higher in proportion than in most similar industries—they are far higher, for example, than those with which the metal miners are contenting themselves without complaint. The anthracite miners (operators and workmen) should clearly perceive that further raising of costs is not only inadvisable but impossible, because it would mean a further loss of the already insecure anthracite markets and a corresponding blow to anthracite labor and capital. Any further increase in mining costs, it is realized, must be passed on to the public; and the public has clearly indicated that in that case it will take its business elsewhere.

It is to be hoped that the outcome will be a more helpful and co-operative form of unionism. The coal industry is a national problem, not so much because of any close organization among coal operators (indeed the Federal Government and coal commissions have complained of the lack of any centralized competent organization of capital with whom parley could be held); it is a national problem, and in time of strikes appears to be a national monopoly, through the recent monopoly of mine labor. What the coal industry needs is freer competition, which indeed has been partly obtained in the present emergency by the increased activity of the bituminous industry.

Close Analysis of Accidents will prevent their recurrence. Any accident that might have caused an injury but did not should be investigated and the result recorded. No accident should be grouped under a single cause, but cross-indexed and cross-recorded under all the various elements surrounding or causing it—negligence, lack of instruction, sickness, feebleness, age, ignorance, or lack of sight of victim where there is one, lack of light, time of day, day of week, faulty track, weather conditions, seam of coal and part of mine.

The Public Doesn't Desire knowledge for its guidance. If it thinks something is being hidden from it, it naturally becomes anxious to find out what it is. With ascertainment completed the interest dies. The facts are no longer news. The papers want "exclusive stuff." If they all get a story, especially without asking for it, they won't take the trouble to print it. But if it's a secret, that's another matter. Perhaps a little greater coal publicity would do no harm.

Seeing That Anthracite is faced by competition from substitutes and that competition can be proved by many public utterances and other unquestionable evidence, it is time that legislation imposing differential taxation on anthracite be repealed, thus lowering the cost on that commodity to the consumer.

# Improved Blasting Methods Increase Proportion Of Lump Coal in Output*

## Standard Shooting Practice Should Be Adopted—Shothole Placement, Size of Cartridge, Kind of Stemming, All Exert Non-Cumulative Influences

By **J. E. Tiffany**†
Pittsburgh, Pa.

SUCCESSFUL coal marketing usually hinges upon the thoroughness of preparation and the percentage of lump contained in the mine product. Methods employed in blasting the coal from the working face and all operations incident thereto are of primary importance because subsequent care in preparation cannot atone for lack of skill in bringing the coal down. In order to obtain a more marketable product and simultaneously increase safety and efficiency in coal shooting it is necessary to standardize all operations incident to mining.

No standard round of shots applicable to all mines is possible because working places differ greatly in width and height. Furthermore, coal beds vary appreciably in texture and in the number and position of the bands of impurity contained. By proper investigation, however, it usually is possible to devise a standard method applicable to any particular mine. How this may be accomplished and the result of tests made by the U. S. Bureau of Mines will be here set forth. These tests show the relations existing between the methods of placing and charging the holes, the actual quantity of lump produced and the possibilities of improving blasting practice. The trials here depicted were carried out in two large mines working the Pittsburgh bed, and in one southern Illinois mine, of 4,000 tons capacity, working the No. 6 measure of that state.

The first two investigations were prosecuted under a fellowship agreement with the Carnegie Institute of Technology; one in the Naomi mine of the Hillman Coal & Coke Co. at Fayette City, Pa., and the other in the Banning No. 2 mine of the Pittsburgh Coal Co. at Whitsett, Pa.

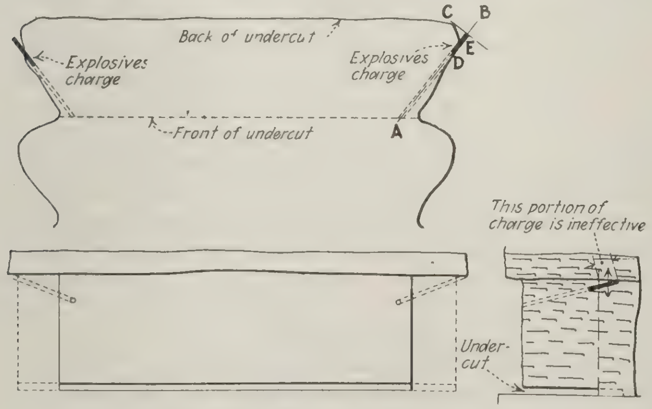


**Fig. 1—A Gripping Undercut**

Sumping the machine at an angle to the rib and withdrawing it in a similar position results in the back of the cut being wider than the front. Rib holes are liable to be drilled into solid coal thus seriously decreasing the effectiveness of their explosive charges.

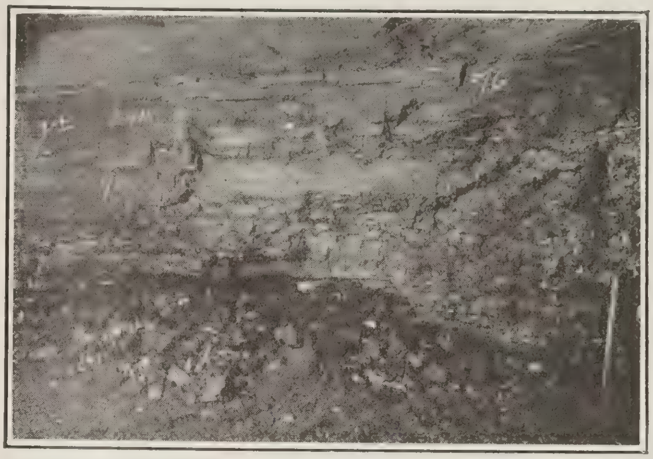

**Fig. 2—Results of a Snubbing Shot**

Snubbing may be accomplished by hand picking, by wedging, by mechanical means or by the use of explosives. This illustration shows the effect of firing a light shot in a shallow hole drilled near the center of the face a short distance above the undercut.

Assuming that it is desired to improve the product of a given mine, how shall the necessary investigation proceed?

A thorough inspection of all working places is the first step. In this work the physical characteristics of the coal bed, particularly as to friability, must be considered. Observations should also be made of the thickness and hardness of each bench, and the position, nature and thickness of the bands of slate and bone, also the character of the roof and bottom. Where shots are fired in working places their effect on the coal, roof and ribs should all be carefully observed. Inspections made in other mines working under similar conditions often prove of value and may furnish worthwhile suggestions for the solution of the problem in hand.

In mines where improvement in the quality of output is desired, a standard method of drilling and shooting is seldom in vogue. The placement and direction of shotholes with respect to the ribs, the roof, and to each other, vary widely. As a rule blasting charges are found to be excessive and not properly confined by a sufficient quantity of incombustible stemming. As a result evidence can frequently be discovered of blown-out shots. Entirely aside from the hazards attending such practices, the explosive has no chance to produce effective results. The coal will be found to be much broken and in many cases is not loosened in a manner suitable for loading onto mine cars.

---

*Abstract of paper entitled "Recent Developments in Shooting Coal" presented with the approval of the acting director of the U. S. Bureau of Mines, before the West Virginia Coal Mining Institute, Nov. 24, 1925. Mr. Tiffany covered the same subject at the Coal Mining Institute of America, Pittsburgh, Pa., Dec. 10, 1925.

†Explosives testing engineer, Pittsburgh Experiment Station, U. S. Bureau of Mines.

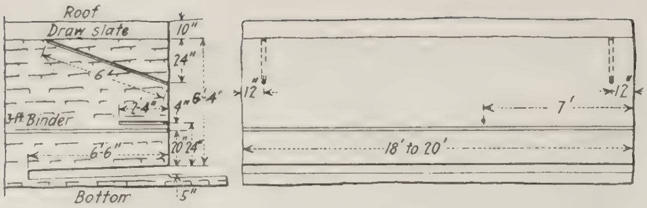

**Fig. 3—Placement of the Snubbing Shot**

In this case the snubbing shothole was drilled 2 ft. 4 in. deep and placed 2 ft. above the kerf and 7 ft. from the right hand rib.

When these observations have been completed, formulation of a new system which may lead to a standard practice in drilling and blasting may be commenced. The method of shooting should no longer be left to the judgment of each individual miner. The quantity of explosive loaded into each hole will also have to be standardized. Different methods must be tried out under strict supervision and, if possible, the coal produced should be screened separately so as to ascertain which practice yields the maximum percentage of lump.

Investigations in the southern Illinois mine referred to continued for more than two months before a suitable blasting method was evolved. During this time no attempt was made to change the practices followed by the miners. During the first month after the standard method was adopted no improvement was noticeable in the quantity of 6-in. coal. During the second month, however, better results became apparent and an increase of 1.53 per cent above the average of the ten months prior to the commencement of the investigation was noted. Some of this improvement may have resulted from the use of 1¼-in. diameter cartridges in place of 1¾ in., which they supplanted. During the second month the lump coal was increased by 2 per cent; this improvement unquestionably being due to the standard methods adopted together with the reduction in cartridge diameter. Through all subsequent months this improvement was sustained and the good results obtained were further improved by instructions given the miners, by closer supervision and by the co-operation of all interested parties, both mine officials and miners.

Close supervision of blasting and all the operations incident thereto is a major factor in any campaign to increase the percentage of lump coal. This should start before the faces are cut. A place that is properly cleaned before undercutting will give better results than one in which the face overhangs and the corners are not square.

**Fig. 4—Tight or Buster Shot in a Slant Hole**

Much of the coal loosened by this kind of a shot merely settles down in place without being thrown or rolled out upon the mine floor. It requires considerable pick work to dislodge it ready for loading.

Fundamentally an explosive must have at least two free faces of coal to work upon in order to bring down the material properly. For this reason it is necessary to produce one of these faces artificially by either hand or mechanical undercutting or by an over-cut, middle-cut or shear. A shearing cut may also be used in combination with either one or both of the other operations. These cuts should be made as carefully as possible in order to obtain rectangular faces. Each cut must be uniform in depth and must not grip at the ribs. If the cut grips at the ribs the tendency is to grip the drillholes also. When such holes are charged and fired they do not bring the coal down in a satisfactory manner and since it is wedged at the ribs it does not roll forward into the working place. This fosters the natural tendency on the part of the miner to use excessive charges of explosive. Such charges do not improve conditions, while they shatter the coal seriously.

Gripped holes are frequently drilled beyond the cut as shown in Fig. 1. When fired, the explosive lying in the solid cannot perform a maximum of useful work, consequently it shatters the coal immediately about it and may exert undesirable force upon the roof. This is particularly the case if coal is left up as a roof protection. This constitutes an additional hazard in mining, for when the roof is injured in blasting greater difficulty and cost is entailed in preventing it from falling.

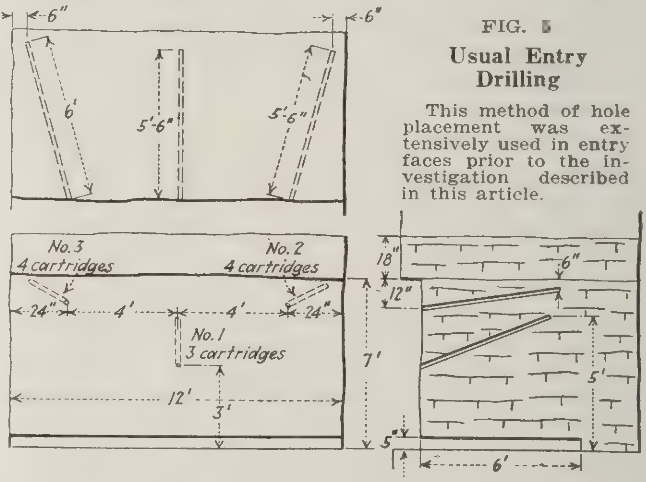

FIG. 5

**Usual Entry Drilling**

This method of hole placement was extensively used in entry faces prior to the investigation described in this article.

Tendency to make cuts gripped at the ribs is common to all types of mining machines, the breast machine included. However, with this latter type another difficulty is encountered, namely, that small pillars or noses of coal, commonly called "sprags," are liable to remain at the back of the undercut. With some types of turret machines, also, a place cannot be cut to uniform depth. It is possible, however, by the exercise of proper care, to cut the ribs in a direction parallel to the line of sights. When undercutting has been completed a still further improvement may in many cases be made by snubbing; that is, by increasing the height of the undercut along its outer edge by picking or blasting.

Where snubbing is practiced the coal usually rolls forward into the room when it is loosened by the blast. This breaks the material less than when the explosive is called upon to perform the double duty of both breaking the coal down and turning it over. In snubbing tests made at the Naomi mine an increase of 5 per cent—from 64.2 to 69.2 per cent—in the proportion of coal passing over a 1¼-in. bar screen was obtained. However, when these same tests were repeated in the Banning No. 2 mine, where the coal has different physical characteristics, snubbing did not always result in rolling it forward. In this mine the coal clung to the ribs and snubbing proved of no particular advantage. While hand snubbing produced more lump coal in the Banning No. 2 mine than was obtained from unsnubbed shots, the improvement was not sufficient to offset the quantity of slack produced in the cutting and snubbing operations.

Fig. 2 shows the result of a snubbing shot placed as shown in Fig. 3. The proportion of lump obtained with this snubbing shot was more than 1 per cent higher than that produced by hand snubbing. In a room 20 ft. wide several tons of coal is picked down in snubbing, only 40 per cent of which is 1¼-in. lump. Almost 10 per cent of slack is produced in such a room as the result of both cutting and snubbing operations.

Tests should, therefore, be made before deciding upon the adoption of snubbing in any particular mine. It will be found that where the coal does not cling to the ribs after being shot, snubbing will permit it to turn over instead of remaining in an upright position. The snubbing operation can be performed by explosives, by hand, either using wedge and sledge or pick, or by mechanical methods, such as air-driven punchers, drills or hammers, or by electric chain machines.

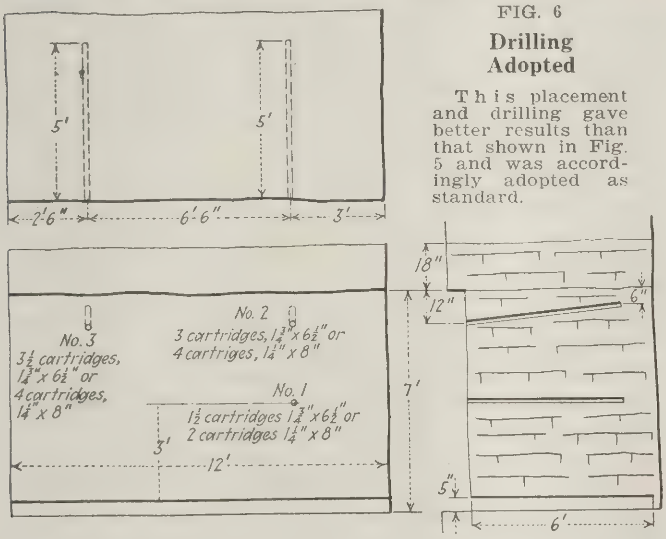

FIG. 6

**Drilling Adopted**

This placement and drilling gave better results than that shown in Fig. 5 and was accordingly adopted as standard.

Undercutting does not yield its full advantages unless the cut is cleaned out before shooting. This detail should be given close attention. The miner or the machine runner's helper should be provided with a scraper or long-handled shovel for this purpose. Bugdust cleaned out from such a cut should be loaded before shooting.

According to L. E. Young, in a paper presented before the American Mining Congress, May 29, 1925, "Data are not available to warrant definite conclusions but the outlook is that a combination of shearing and snubbing will prove to be the most desirable practice for mechanical loading; for the success of mechanical loading depends very largely on how the coal is shot down." To this might be added the further fact that improvement will accrue to proper placing of the shotholes, since this forms one of the most important technical details of blasting operations. In order to shoot a place satisfactorily, either for hand or for machine loading, the ribs must be cleaned properly and the mass shot be so shaken up that it can be shoveled with as little pick work as possible. Improperly placed holes, which have to be heavily loaded in order to bring down the coal, will shatter the material adjacent to the explosive charge, while at greater distances from it fissures will be produced even in the material left in place. This adds to the difficulty of firing subsequent shots. The quantity of coal thus shattered decreases as the placement of the holes is improved, while simultaneously the quantity of explosive necessary will be decreased.

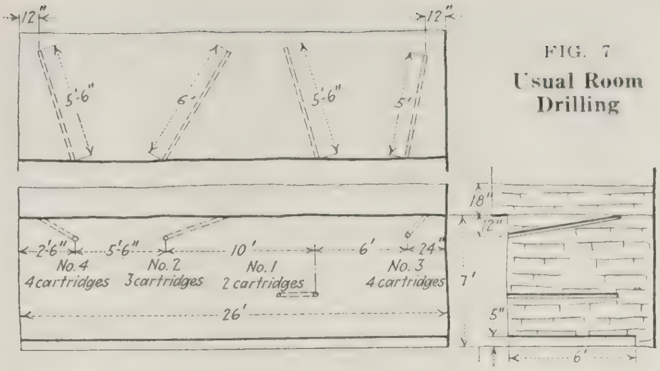

FIG. 7

**Usual Room Drilling**

Proper placement of shotholes will depend upon the texture of the coal and the direction and nature of the face and butt cleats. In the Banning No. 2 mine, tests were conducted with working places 10 and 18 ft. wide on both the butts and faces. Shot holes were placed in the same manner for each test and the same brand of explosive was used. As might have been expected, the narrow butt workings gave the poorest results, 54 per cent of lump, while the wide faces afforded the best.

Shotholes that slope up at an appreciable angle, such as are commonly employed in the Pittsburgh bed, have many disadvantages, which will be discussed later. Fig. 4 shows the result of firing a tight shot in a wide butt working.

In the tests in the Pittsburgh bed, where the coal mined ranges from 6 to 7 ft. high and the working places were 10 ft. wide in entries and 20 ft. wide in rooms, it was found that only two holes were necessary. In most places where lump coal is an important consideration, better results are procurable by using only two holes. Where the coal is of a tougher nature, however, especially if it becomes necessary to use heavy charges of explosive, it is found better to employ more holes charged lighter. A common practice followed in the Pittsburgh bed is to place the holes from 12 to 15 in. from either rib and 2 ft. below the draw-slate. Such holes are drilled parallel to the rib but sloping upward toward the roof at such an angle that the farther end is about 4 in. below the draw-slate and 6 in. in front of

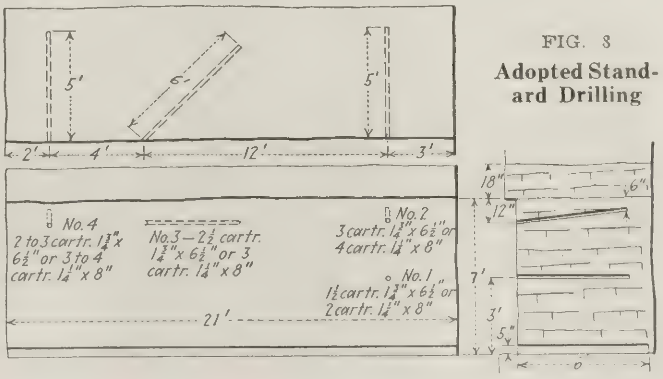

FIG. 8

**Adopted Standard Drilling**

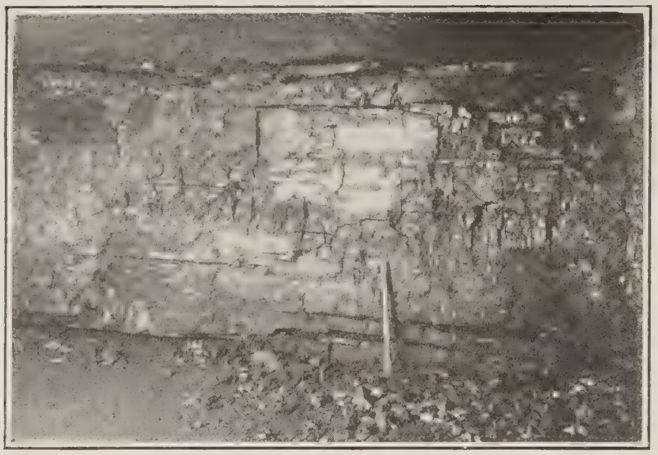

**Fig. 9—Result of a Tight Shot in a Slant Hole**

This coal merely is cracked and will require quite a bit of picking to bring it down ready for loading out. This imposes much more work on the miner than a shot that rolls the coal well out on the floor.

the rear of the under-cut. In other words, a vertical line dropped from the rear end of the hole would reach the kerf 6 in. ahead (that is, nearer the face) of the back of the under-cut. As a rule about 2-in. holes are drilled. These are commonly employed in the coke regions of Pennsylvania where lump is no particular object. One hole, known as a "buster" or breaker shot, is placed at the center of the face, or at some point between the rib holes.

As a rule, in narrow work the necessity for a third hole will depend largely upon the texture of the coal. In southern Illinois where the cleats are less pronounced and the texture is of a tougher nature, a third hole was drilled, as shown in Fig. 5. After making a number of tests it was found advantageous to place No. 1 hole 3 ft. above the bottom and the same distance from the rib. This was drilled relatively flat, as shown in Fig. 6.

In the No. 6 bed of southern Illinois the "blue band," a streak of hard gray shale, about 1½ in. thick, occurred in the mine investigated at a uniform height of approximately 18 in. above the floor. This had to be considered when placing the shotholes. Presence of this blue band led to the adoption of snubbing, usually accomplished by firing a snubbing shot. The hole for this shot should be drilled in an almost horizontal position, as shown in Fig. 7. Fig. 8, however, shows the method of drilling finally adopted as standard. Four holes are used, their numbers on this drawing indicating the order in which they are fired.

**Fig. 10—Result of a Tight Shot in a Flat Hole**

In this case the coal is much more broken than in Fig. 9. However, snubbing before shooting probably would have improved the results attained.

Side holes should always be drilled parallel to the line of sight and should be from 1 to 3 ft. from the rib, depending on the kind of shear which they will produce. Tests made in the Pittsburgh bed showed that for a tight shot a distance of 12 in. was most advantageous, both from the standpoint of lump production and that of obtaining a good shear. Better results, however, were obtained in the tougher Illinois bed with holes placed 3 ft. from the rib.

Relatively flat holes drilled 10 in. below the top of the coal produced 5.1 per cent more lump than did those started 24 in. below the top and slanted upward. Fig. 9 shows the result of firing a tight shot with a slating hole, while Fig. 10 displays the result of the same kind of a shot with a flat hole placed as shown in Fig. 11. The results of a butt shot are shown in Fig. 12.

No hole should ever be charged with a greater amount of permissible explosive than the limit prescribed by the Bureau of Mines, or 1½ lb. per shot. The present published list of permissibles contains brand names of about 150 explosives. Those commonly used in coal mining are to be found in Class 1a, the principal ingredient of which is ammonium nitrate. Both the safety and physical characteristics of these explosives have been tested by the Bureau.

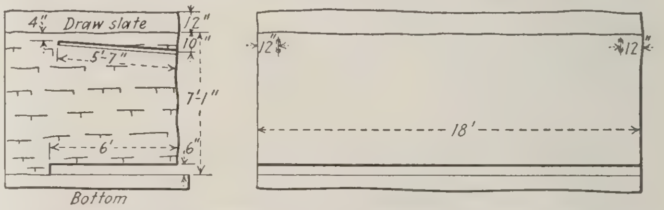

**Fig. 11—Placement of Flat Holes in Room Face**

No snubbing was here attempted. Pitching the holes flat or nearly so allows the explosive to exert its force in a direction at right angles to the bedding planes of the coal.

Permissible explosives possess three characteristics which influence their production of lump coal, namely, density, unit deflective charge, and rate of detonation. The Bureau publishes the weight in grams of the 1¼ x 8-in. cartridges of each explosive. These weights vary from 137 to 181 gm. or more, corresponding to a stick count of 165 to 125 per 50-lb. case. In the lighter brands 3⅓ sticks of 1¼x8-in. size weigh about a pound; in the heavier varieties about 2½ sticks. The lighter a cartridge the greater will be the distance along the borehole throughout which the explosive force generated by it will be distributed, provided a unit deflective charge is considered. The unit deflective charge is that weight of an explosive in grams which will give the same swing on the ballistic pendulum as 227 gm. (½ lb.) of the 40 per cent, straight nitroglycerin dynamite adopted as a standard by the Pittsburgh testing station of the Bureau of Mines.

It has been found by tests conducted on five different brands of explosive, used under identical conditions but in quantities proportioned according to their respective deflective charges, that each explosive brought down the same quantity of coal, with, however, different proportions of lump. The rates of detonation of these explosives vary and to this was attributed the difference in the percentage of large size produced.

The rate at which a file of explosive detonates in feet or meters per second is known as its rate of detonation. Fig. 13 shows the relation between the rate of detona-

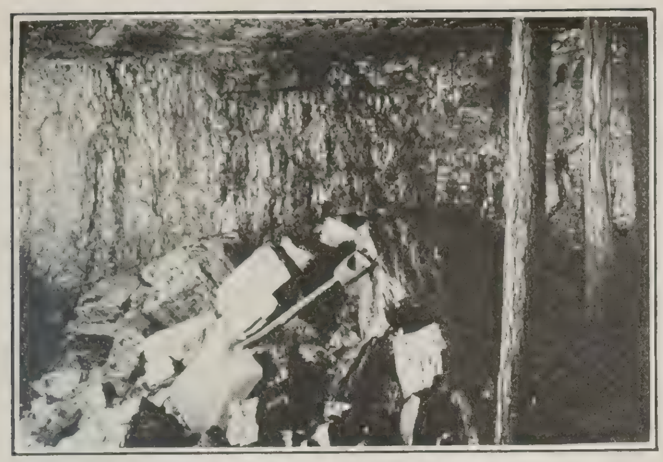

Fig. 12—Result of a Butt Shot

At many, if not most, coal operations the percentage of lump coal in the mine product determines the margin of profit that can be made, because the lump is the only grade that can be sold at a price appreciably exceeding the cost of production. Apparently this shot produced a satisfactory proportion of this size.

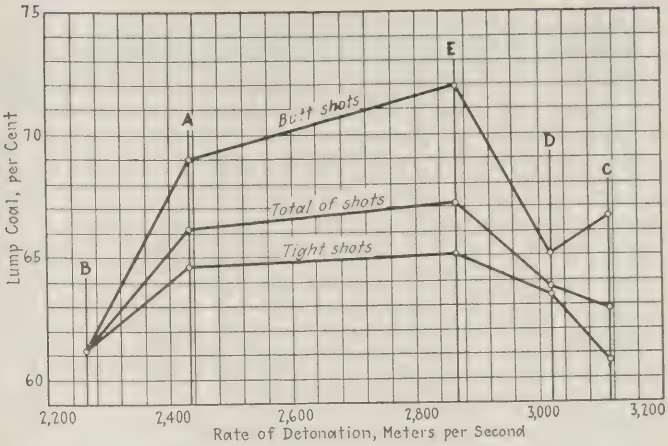

Fig. 13—Influence of Detonation Rate on Proportion of Lump Produced

Naturally, tight shots produce less lump than butt shots. A certain rate of detonation also tends to make the percentage of lump a maximum. Any rate greater or less than this critical speed will have an adverse effect on the size of the coal produced.

tion and the percentage of lump coal produced in the five tests made. The highest point of these graphs indicates the permissible explosive having the detonation rate most suitable for the physical texture of the coal mined. Any explosive having a detonation rate either greater or less produces a decreased percentage of lump, this decrease being proportional to the variation in the detonation rate.

In loading a borehole in coal all the cartridges required should be placed together at the rear of the hole with the primer (the cartridge containing the detonator) placed last or nearest the collar. The fulminate end of the detonator should point toward the main body of the charge. A wooden tamping stick should be used to push the cartridges home. Incombustible stemming only should be employed, as coal dust or slack invites disaster by explosion. Moist clay forms an excellent stemming material and can be made up into dummies. Where a plastic material is not available, however, the stemming may be placed in tamping bags. The first two dummies should be pressed lightly against the explosive charge, while the remainder of the stemming should be tamped forcibly into the drill hole, which should be filled to its mouth. In firing such a charge a lead wire not less than 100 ft. in length should be employed. The shotfirer should never detonate a shot except from some point where he cannot be injured. Wherever possible it is good practice to fire one hole at a time and load out the coal brought down by it before firing the next shot. Tests in a Pennsylvania mine have shown that when all the coal loosened by the tight or buster shot was loaded before the butt, or second shot, was detonated, 2.6 per cent more lump coal was produced than when only about half the coal loosened by the tight shot was loaded out before the second shot was detonated.

As a rule, best results are attained when cartridges of appreciably less diameter than the hole into which they are loaded are employed. In the Illinois tests where 2-in. holes were loaded with 1¼ x 8-in. cartridges, in place of 1¾ x 6-in., because of the excessive quantities of explosive used prior to the tests, the substitution could be made on a stick-for-stick basis. Where only a proper charge of 1¾ x 6-in. cartridges have been employed, about one more cartridge of the 1¼ x 8-in. size was necessary. By this means the air-space as well as the length of the charge was increased. Theoretically, the use of a cartridge of small diameter should result in the production of a greater percentage of lump coal, because when the same weight of charge is used the smaller diameter greatly increases the length of charge.

Quantitative tests have shown that when 1-in. cartridges were substituted for those 1¼ in. in diameter, 4.9 per cent more lump passing over a 1¼-in. screen was produced. In actual practice, however, a cartridge as small as 1 in. should hardly be employed, because, as

Fig. 14—Tight Shot With Air Spacing

In loading this shot a wire spacer was interposed between the explosive charge and the stemming. This afforded a cushion against which the explosive might act. The explosive force thus was spread over a larger internal area of the borehole than would have been the case had the spacer been omitted.

the diameter is decreased, deterioration of the explosive in storage is increased. A 1⅛-in. cartridge, however, may be used to advantage under ordinary circumstances.

Methods other than decreasing the diameter of the cartridge may be employed for aircushioning. For example, a wire spacer or a paraffined pasteboard tube may be used, or rock dust may be employed for all or a part of the stemming. Under certain conditions more lump coal may be produced by a combination of two or more of these methods. The use of spacers, however, of whatever kind, does not meet the requirements of some state laws and up to the present time the Bureau of Mines has neither approved nor condemned their use.

In using a wire spacer the explosive is placed in the bottom of the drill hole, the spacer pushed in next and the remainder of the hole tightly tamped to the collar with clay stemming. By this method an increase of 5.4 per cent in lump coal has been obtained. Fig. 14 shows the result of a tight shot loaded in this manner. An increase of 7.4 per cent in lump was obtained by combining this method with snubbing. Fig. 15 shows the result of a tight shot and Fig. 16 that of a butt shot with this type of loading.

Investigations have also been made with rock dust stemming and methods of loading that comply fully with the statutes of Pennsylvania, which require that a hole must be tamped solidly with incombustible stemming throughout its entire length. For this reason, in the test all dummy cartridges were made of the same diameter as the hole, which in turn was entirely filled. Two different rock dusts were employed, namely, a limestone and a shale dust. About 85 per cent of each variety would pass through a 200-mesh screen. Both dusts were tested with a 6-in. clay plug tamped in the collar of the hole. The limestone dust was also tried without clay plug and with one 24 in. long.

Under similar conditions of tamping, the limestone gave a higher percentage of lump coal than did the shale dust. This variation may be explained by the different actions of the two materials. The limestone appeared to act as a medium for transmitting the force of the explosion uniformly throughout the entire length of the drillhole, while with the shale the action more nearly approximated a cushioning effect due to the packing of the dust into a smaller volume.

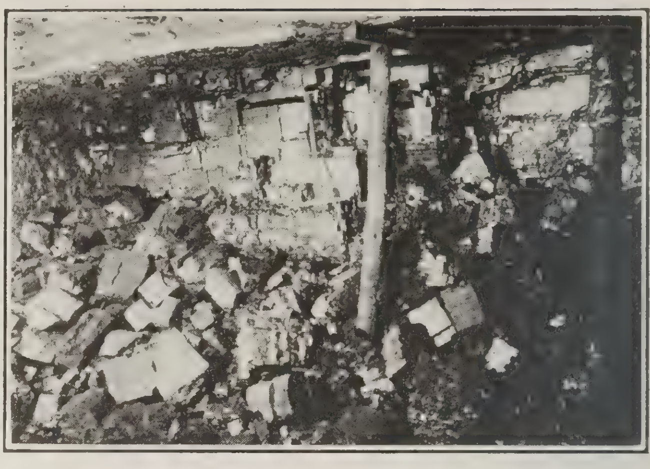

**Fig. 16—A Butt Shot Snubbed and Air-Spaced**

Note the large percentage of lump coal produced. Such results as these indicate emphatically that the realization for the total output may be appreciably enhanced by departing from the "by-guess-and-by-gosh" methods followed by most miners in the matter of shooting, and substituting therefor carefully systematized practices that have been painstakingly established as the result of actual experiment.

When rock dust stemming was employed in a slating hole, 4.3 per cent more lump coal was produced than with moist clay, while 5.1 per cent more large material resulted from a flat hole than was obtained with moist clay in a slant hole. However, when these results were compared with those obtained with a flat hole and moist clay stemming, the increase was only 0.8 per cent.

After a standard method of shooting has been worked out carefully and found applicable to the majority of places within a mine, it should be put into effect and rigidly adhered to. A standard method properly enforced, even though it may not be the best available, is far better than as many different ways of shooting as there are miners employed.

Coal mine executives desiring to increase the proportion of their lump product should carefully consider the following details: Drilling and shooting practices should be standardized and closely supervised. The ribs should not be permitted to grip the under-cut, which should be of uniform depth. All bugdust should be cleaned out of the under-cut with a scraper or long handled shovel before the face is shot. After each shot the coal brought down by it should be loaded out. Side holes should not grip the ribs. All shot holes should be drilled parallel to the bedding planes. Overloading shotholes should be avoided; this will decrease the proportion of lump coal. Each hole should be tamped full with incombustible stemming material. If proper attention is paid to these details, an increase in the proportion of lump coal produced may be confidently expected.

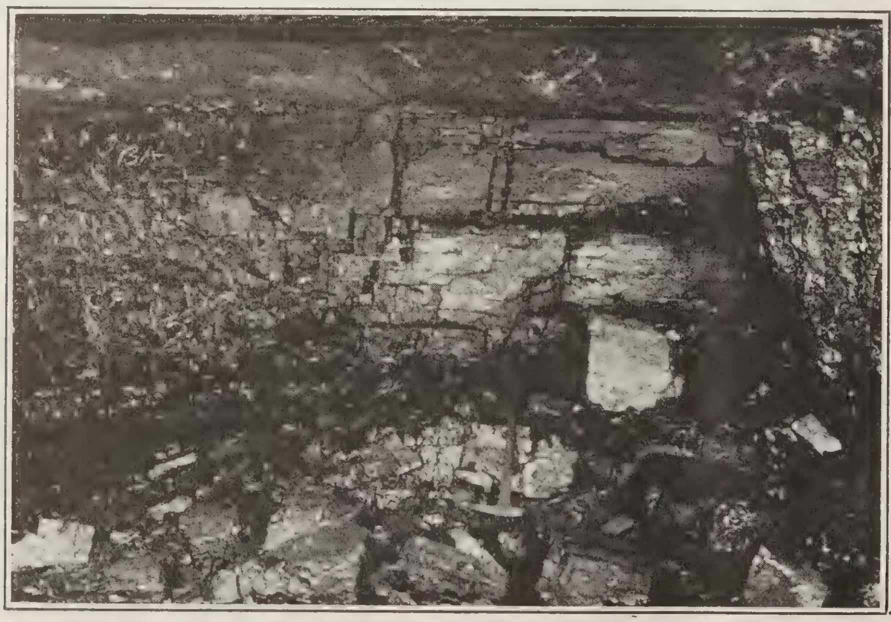

**Fig. 15—Effect of Both Snubbing and Air-Spacing**

This was a tight shot, yet as may be seen a fair proportion of lump was realized. Any one improvement in shooting may appreciably increase the proportion of lump yielded, but these betterments are not addable, that is, total improvement secured from two improved practices will not amount to the sum of the betterments attributable to these methods used singly.

# Fordson Engineers "Span" Their Difficulties

By **J. H. Edwards**
Associate Editor, *Coal Age*
Huntington, W. Va.

DISPOSAL OF MINE REFUSE by aerial tram is now commonly employed at many of the larger mines in the mountainous sections. Usually the tramway carries the material up over the top of a steep hill and dumps into the adjacent hollow. In such cases the track ropes are supported directly from towers located on either side of the valley.

A somewhat different set of natural conditions was encountered at mine No. 5 of the Fordson Coal Co., at Stone, Ky. There it was desired to dump the refuse along the center of a long gradually-ascending hollow, the mouth of which is close to the tipple. Because of the distance to the outer tower and the contour of the ground it was necessary to provide several intermediate supports for the track cables. Construction of towers for two of the four supports would have been exceedingly expensive, and, moreover, at these points towers would have been liable to damage from burning refuse. At these two points aërial supports are used. The ropes run at right angles to the track cables and are anchored on each side of the valley.

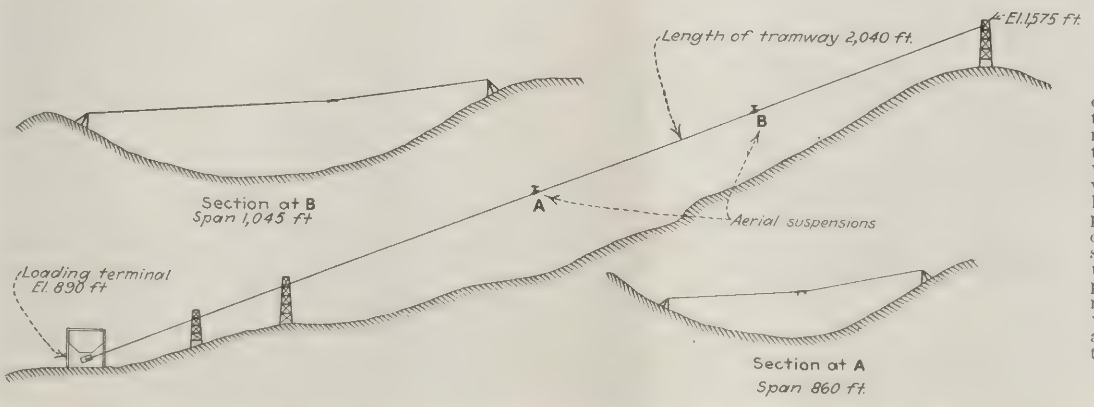
**Tramway Carries Refuse 2,040 Ft. Over Route Requiring Two Aerial Suspensions to a Dump 685 Ft. Above the Tipple**

The construction of supporting towers at every necessary point along the cableway was economically out of the question because of the contour of the ground. So at two locations suspensions were installed, one of them requiring a rope span of 860 ft. and the other a span of 1,045 ft. The inset of the central illustration shows one of the suspension fittings which consists of a box girder about 10-ft. long with a sheave at each end and with saddle-carrying legs suspended to provide flexibility. The drawing accompanying this article shows the locations of the two aerial suspensions. In the view at the right, taken from the operating platform at the dump, looking back along the line, smoke hides the aerial suspensions. Two buckets are used on the tramway, one going out loaded with 4,000 lb. of refuse, while the other returns empty to the tipple.

A double cable is used to support the aërial hanger. This hanger consists of a box girder about 10 ft. long having a sheave at each end. Neither of the suspension ropes is dead-ended at the hanger but instead both are looped around the sheaves. The saddles supporting the track ropes are fastened on brackets projecting from the vertical legs which are suspended from the short girder.

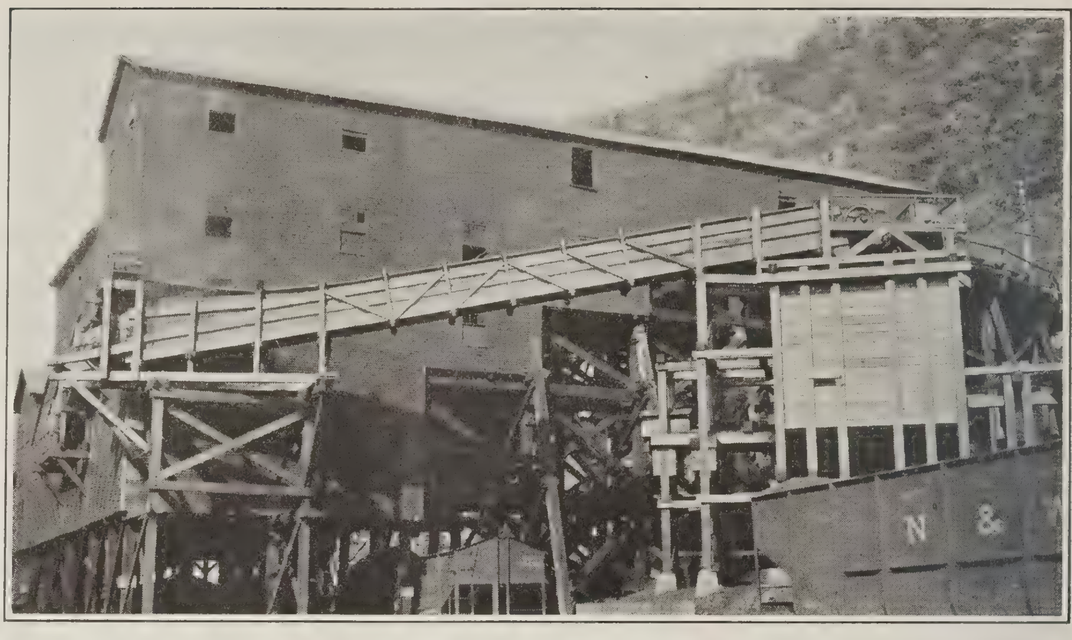
This tramway at No. 5 mine is one of five being installed by the Fordson Coal Co. for refuse disposal. All are of the two-bucket type, one bucket going out loaded while the other returns empty. Except for the aërial suspension feature, a description of the No. 5 tramway holds good for those being installed at the other mines.

The bucket capacity is 50 cu.ft., or, expressed in another way, it holds approximately 4,000 lb. of refuse. The tramway is designed for the disposal of 50 tons per hour of material weighing 80 lb. per cubic foot. A feature of the design is the arrangement at the loading terminal for one-man operation. The electrical controls



**The Ford Line**

With a distance of 2,040 ft. between the loading terminal and the outer tower, and a deep valley between, it was necessary to have several supports for the track cable. The two supports near the upper end were provided by spanning the valley with cables running at right angles to the main ropes.

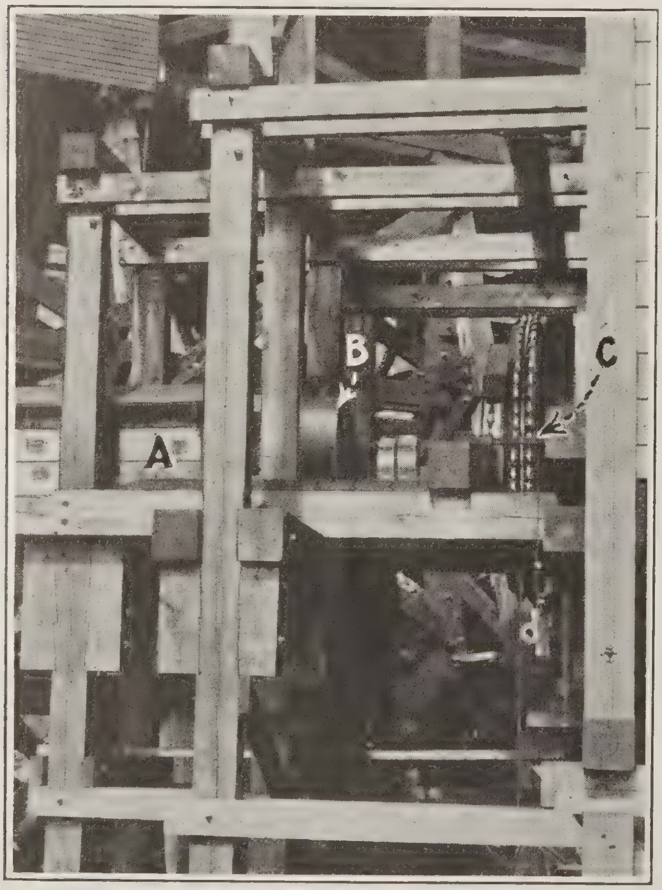


**Belt Feeds Rock to Tram Bin**

This shows how the refuse is conveyed from the No. 5 tipple to the bin of the loading station. The cars of refuse are dumped in the tipple into a bin which feeds directly into the large conveyor. That coming from the picking tables is carried to the main conveyor by a small conveyor at the left, on the side of the tipple.

are located on the platform between the bucket-loading positions. The operative needs to move but a few steps to open the gates which fill the buckets and to manipulate the control and brake mechanism of the driving equipment.

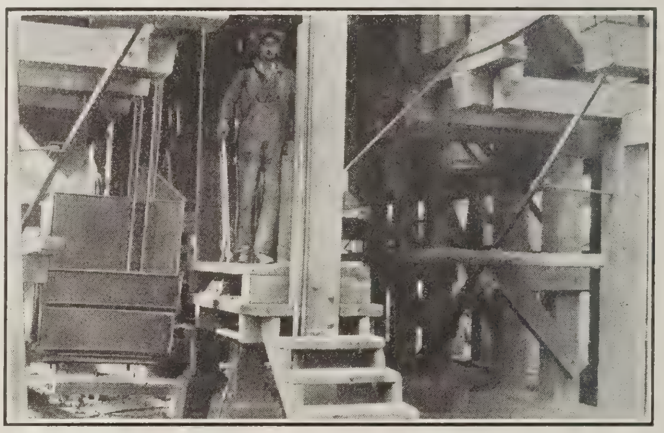
The motor driving the traction cable is connected to the sheave through a speed reducer. Much space is saved by this arrangement as compared to a belt drive or to a drive through several reductions of spur gearing. A reducer has the additional advantages of efficiency, reliability, and safety. The motors, reducers and other mechanical parts are the same at each aërial tram installation. This is a decided advantage from the standpoint of successful operation, maintenance and repair.



**Driving Mechanism of the Tramway**

The use of a speed reducer simplifies the installation. Maintenance cost is held to a minimum by using the same type and size motors, reducers, etc., at the five installations.

Where the tipple is not modern it is usually difficult to arrange for elevating the refuse to the bin of the bucket-loading station. An illustration shows how this was done at the No. 5 mine. The fact that the old wooden tipple will probably be replaced within a few years by a steel structure, no doubt influenced the method used. That refuse which is loaded separately into mine cars is dumped into a bin which feeds directly into the conveyor extending from the corner of the tipple to the top of the loading station. The refuse from the picking tables is elevated into the main conveyor by the short conveyor which, in the illustration, can be seen along the end of the tipple.



**At the Dump End of the Line**

This shows the operator's platform under the bin at the loading station. The controller and brake lever are within 4 ft. of the gates through which the refuse is loaded into the buckets, thus providing one-man operation. The 50-cu.ft. buckets carry about 4,000 lb. of refuse.

Although the topography of the ground near each mine is different, the methods employed at No. 5 will in the main be duplicated. However, where conditions are such that considerable expense may unnecessarily be involved, variations, no doubt, will be made in the plans.

# Recovery Work at Rockwood Required Much Skill

## After Explosion Killing Ten Men in Reopened Fire Area of Tennessee Mine, Crews from Four States Labored in Trouble Zone

By **R. M. Lambie**
Chief, West Virginia Department of Mines, Charleston, W. Va.

MEN OF FOUR STATES on Oct. 22 took part in the recovery work that followed the explosion last summer in the Rockwood mine at the foot of the Cumberland Mountains in Roane County, Tennessee. The blast occurred at 5 o'clock on the morning of July 23 in the Rodgers Entry of the mine, killing ten men, including the mine superintendent, just as they were beginning anew a fight to extinguish a fire that had been sealed up for three months. Fire in the mine assumed such proportions that the affected zone had to be sealed off for three more months before the bodies of eight of the ten men could be removed. Picked men from Alabama, West Virginia, Pennsylvania and Tennessee did the work.

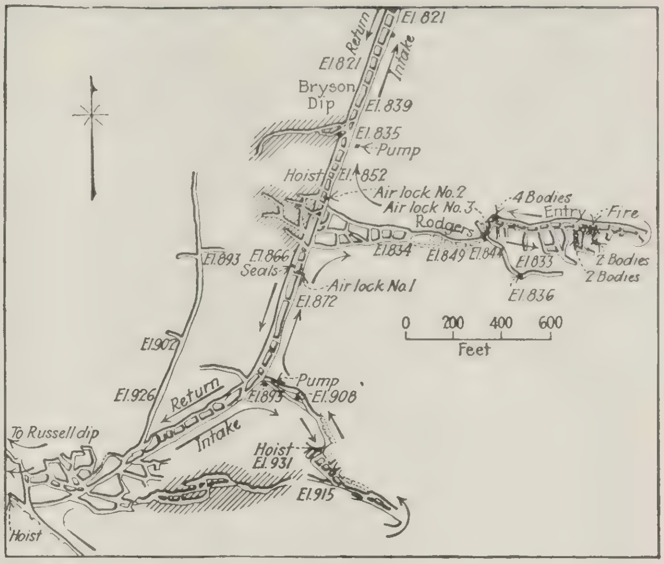
This mine is owned and operated by the Roane Iron Co. It was originally opened by Gen. John T. Wilder in 1868. The coal mined is the Sewanee seam. This seam has some unique features, some sections being on the pitch, others being level and irregular in thickness, ranging from 2 ft. to 30 ft. Owing to the uncertainty of the seam, no regular and uniform plan of development can be projected or carried out, as one can only be governed by conditions.

The mine is divided into three sections, each section having a separate ventilating current. The fan is located approximately 150 ft. above the level of the drift, and forces into the mine workings 150,000 cu.ft. of air per minute, which returns to the main entrance and two other openings back on the mountain where the coal outcrops. This mine liberates explosive gas irregularly, but is operated with open lights. Fire bosses make their examinations daily preceding the entrance of the workmen.

### CONDITIONS IN THE RODGERS ENTRY

The Rodgers Entry, in which the explosion occurred, is turned off the Bryson Dip and is worked on the double-entry system. The entry dips rapidly from the mouth for 300 ft., then continues level. The air course to this entry is irregular, some points being 20 ft. below or above the level of the entry. For a distance of 600 ft. from the mouth of the entry there is room for only the heading, air course and sidetrack, due to rock faults on both sides. The coal area then widens. Rooms are turned to the right, and the air course meanders around following the line of fault. This irregularity of the seam presents some unusual problems in ventilation and transportation, and makes this an expensive mining proposition. All of the coal produced is used at blast furnaces.

The cause of the explosion is undetermined, but the consensus among local mining men is that an accumulation of gas was ignited by the rekindling of a mine fire. The fire had been burning since April 18, 1925, and had been sealed up for ninety days. After reopening the fire zone, the entire area was explored and men began to clear up the slate falls and load out the coke. While this was going on heat and fire were discovered. Six men were detailed as water carriers and three were assigned to load out the burning coals. This work was in charge of the mine superintendent.



**Map of Affected Area**

The troublesome fire and the uneplained explosion occurred in Rodgers Entry, July 23, 1925. That part of the mine was sealed off at once and the bodies of eight of the ten men killed were left in the workings until Oct. 22 when the recovery work was carried out.

### EIGHT BODIES LEFT ENTOMBED

Then came the explosion. The ten men were killed. The bodies of two of them, being only a short distance from the mouth of the entry, were found soon after. The smoke became extremely dense, and since it was apparent the fire was burning, it was deemed best to seal up these entries again, leaving eight bodies entombed.

It was impossible to place seals in Rodgers Entry at the point where they were formerly located, so a location 50 ft. outby the mouth of this entry was decided upon. Only two seals were required to seal the Bryson Dip and Rodgers Entry. Pipes were placed in these seals, and at weekly intervals air samples were taken and analyzed. Analyses showed a rapid decrease in the oxygen content with a heavy increase in methane. The sample taken on Oct. 21, 1925, showed the atmospheric condition inside the seals as follows: Carbon dioxide ($CO_2$), 3.3; carbon monoxide ($CO$), 0.0; oxygen ($O_2$), 0.7; methane ($CH_4$), 72.0 and nitrogen ($N_2$), 24.0.

### BUILD AIR LOCK ON HAULWAY

A fresh air base was established 500 ft. outby the seals. Here all modern equipment for use in recovery work was assembled. On the morning of Oct. 22, an air lock was built on the haulway outby the seal. This air lock was a heavy frame of two-by-fours with four ply of heavy white duck. A door 42x30 in. was made in this air lock with a double-ply check inside and outside. At this point the air registered 10,000 ft. per minute. This being inadequate, it was necessary to regulate the current on the other two splits. This change increased the volume at the breakthrough outby the air lock to 22,000 ft. of air per minute. No. 1 seal was then broken through, and rescue team No. 1, composed of five men, entered with self-contained breathing apparatus.

This team explored a distance of 800 ft. and decided upon a location for air lock No. 3. They then returned to air lock No. 1 where team No. 2 was stationed with apparatus ready to come to their aid had it been necessary. After a consultation, team No. 2 entered the sealed area and proceeded to a point on Bryson Dip where a rock stopping was taken down and air lock No. 2 was built. This was to cut off the Bryson Dip and lessen resistance.

After this had been completed, team No. 1 again entered the irrespirable atmosphere to the point decided upon for air lock No. 3 and built it before returning. Then both outer seals and air lock No. 1 were taken down and the air permitted to circulate to the points outby air locks Nos. 2 and 3.

### Ventilating Current Interrupted

Every precaution was taken from the fan to the innermost workings, and men were placed at stated distances along the travelingways. Unexpectedly the fuses on the electric line to the fan burned out. This caused an interruption in the ventilating current as it took some time to get the auxiliary steam fan in operation and the ventilation restored to normal. During this interruption a small quantity of methane leaked through the air lock as the pressure inside the seal was greater than the atmospheric pressure. Ventilation was conducted in the usual manner, that is, closing up the breakthroughs with temporary stoppings as the advance was made.

After cleaning out the gas to air lock No. 3, and when all places in advance workings had been explored, this air lock was removed and the air conducted throughout the entire section. This made it possible for the stretcher bearers to go without masks to the points where the bodies were found by the rescue squads.

### Apparatus Worked Perfectly

It took eighteen working hours to recover the bodies. Fourteen hours of this time was spent by the rescue teams under oxygen. All machines functioned perfectly, which showed extreme care on the part of the attendants at the base.

The men used in recovery work at Rockwood were these:

Team No. 1—W. H. Forbes, Huntington, W. Va.; Frank Cash, Birmingham, Ala.; George McCoy, Rockwood, Tenn.; Robert Lilly, Mount Hope, W. Va., and R. M. Lambie, Charleston, W. Va.

Team No. 2—W. J. German, Huntington, W. Va.; Clifford Saxon, Birmingham, Ala.; Harry Burdelski, Pittsburgh, Pa.; Arthur McNeeley, Rockwood, Tenn., and R. M. Lambie, Charleston, W. Va.

Other apparatus men who alternated with those on rescue squads were: George McCaa, Pittsburgh, Pa.; Dr. Merryweather, Birmingham, Ala.; W. S. Wilson, Rockwood, Tenn.; George Harden, Rockwood, Tenn., and Wm. Yant (Chemist), Pittsburgh, Pa.

Men in charge of the base were: C. O. Morris, Charleston, W. Va., and Stockton Gaines, Charleston, W. Va.

Inspectors patrolling intake and return were: Zach Evans, Handley, W. Va.; Andrew Holden, Dayton, Tenn., and George B. Thom, Decherd, Tenn.

---

# Oxyacetylene Apparatus Has Standardized Connections

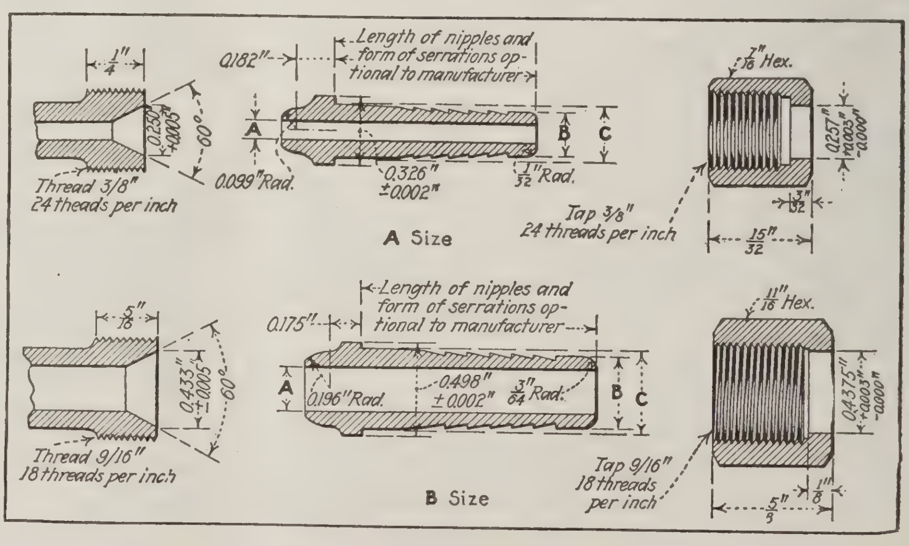
In the past, users of oxyacetylene welding and cutting equipment have experienced inconvenience when attempting to use the product of one manufacturer in conjunction with that of another. Thus in many instances a torch or hose of one make could not be attached to the regulator of another maker without the use of a special adapter. The trouble experienced was exactly analogous to that encountered before the standardization of bolt threads when much time was lost in every industrial establishment through the attempt of the workman to mate a "nut that was a little bit too small and a bolt that was a little bit too big."

The need for standardization of oxyacetylene equipment, particularly hose connections became so urgent that several manufacturers of such apparatus have agreed upon certain standard dimensions which will be adhered to by all, on and after Jan. 1, 1926. These dimensions are shown in the accompanying drawings, the *A* connections being for small torches and the *B* for large ones. Certain dimensions on these connections are optional with the manufacturer such as the length, number and contour of the hose serrations, but all threading and other important details are standard.

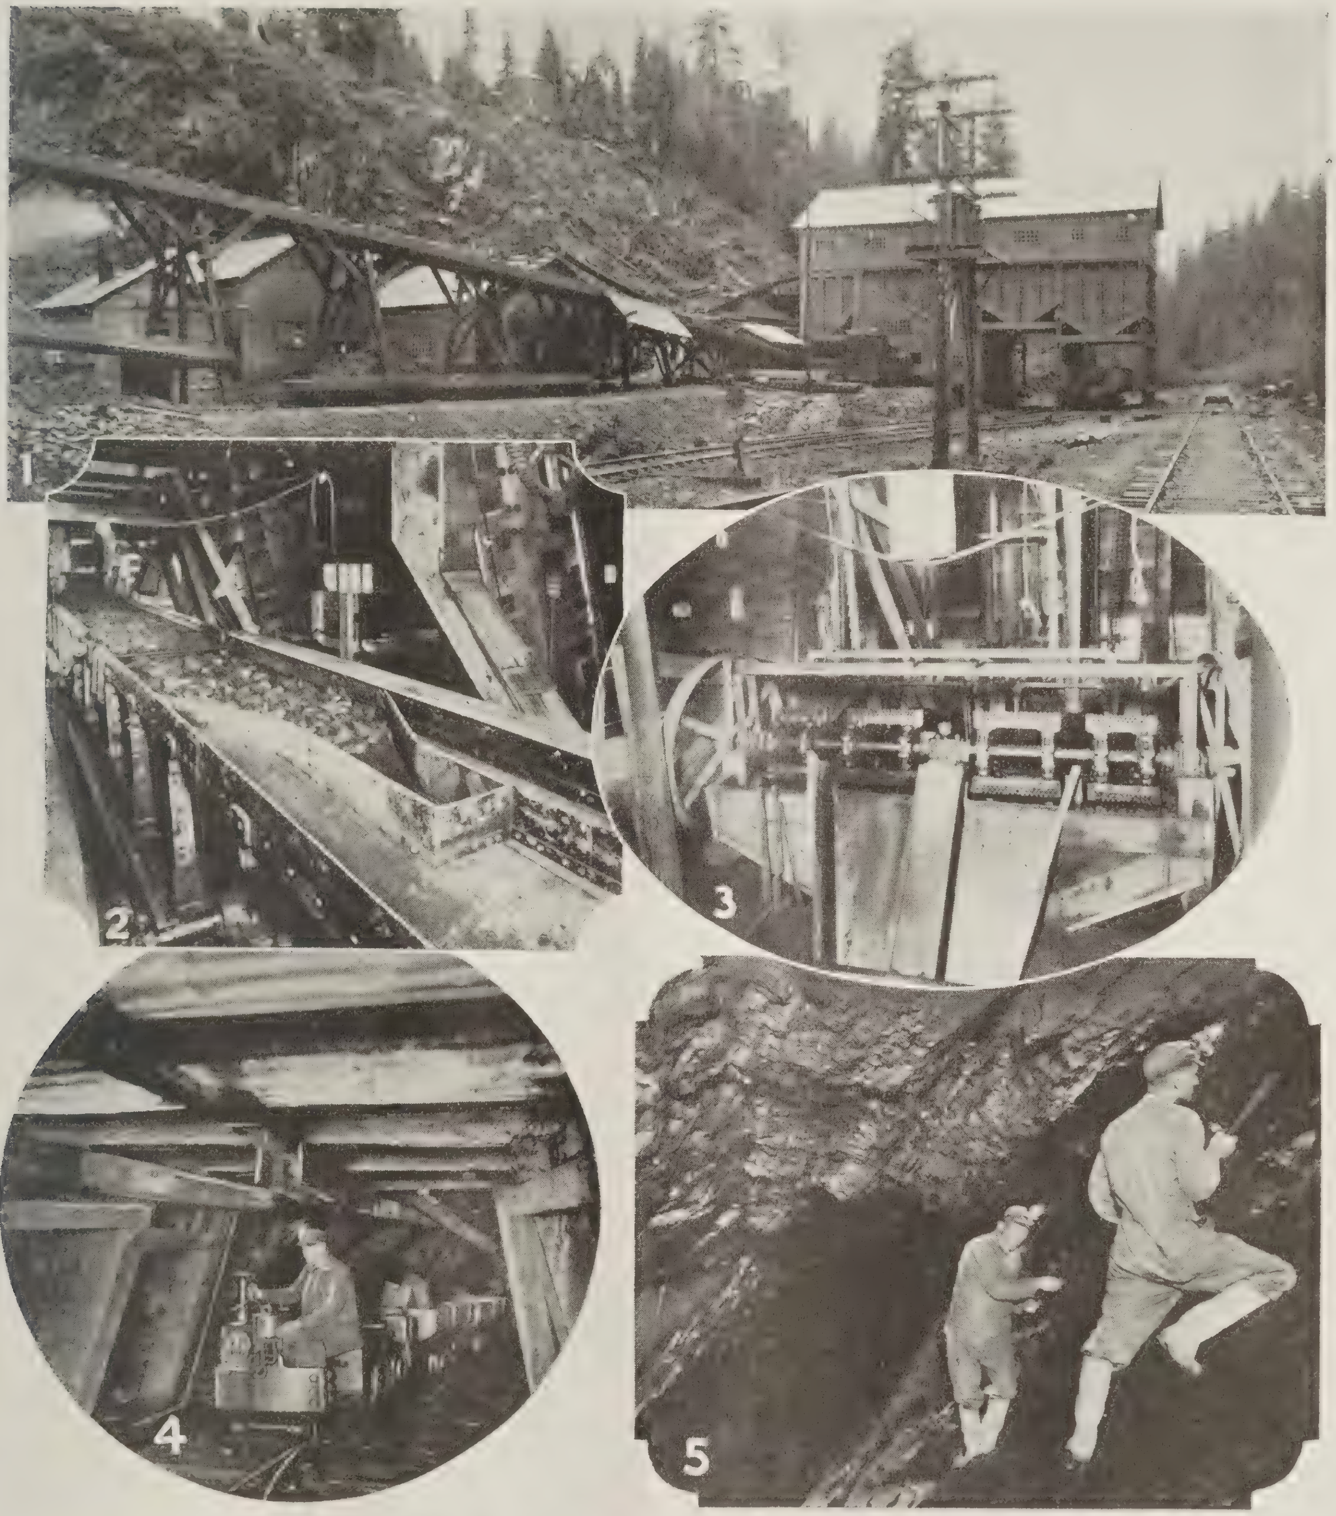
One other detail has been standardized. In order to eliminate the possibility of placing an oxygen hose on a fuel gas nipple or vise versa, righthanded threads have been adopted for oxygen connections and lefthanded ones for gas.

**Standard Design of Hose Connections**

All vital dimensions are made standard so that equipment from different manufacturers can be used without necessity for adapters. Oxygen connections are made with right hand and gas connections with left hand threads. All possibility of getting such connections interchanged is thus obviated.



# *Mining and Preparing Coal in the Far West*



### Another New Mine in the Pacific Northwest—Black Carbon, Near Seattle, Wash.

This plant of the Black Carbon Coal Co. in Pierce County, about 45 miles from Seattle, has been progressing through various stages of construction for three years. Now it is getting into its stride and is expected to produce 250 tons a day. Six seams of coal underlying the company's property contain more than 10,000,000 tons.

Mining is by hand on the chute-and-pillar system in coal that normally pitches about 60 deg. as shown in No. 5. By motor haulage (No. 4) the mine's output is delivered to the slope and hauled out by an endless rope. Drop bottom cars deliver into bins feeding balanced vibrating picking table screens (No. 2) separating the coal into three sizes to be washed in jigs. The discharge end of one is shown in No. 3. From the jigs all the coal goes back into a common drenching tank. It is removed by a 50-ft. flight conveyor over a fine screen and sprayed under high pressure before it reaches a revolving screen making three sizes for loading.

# Union Pacific Coal Co.'s Code of Standards—II[*]

### Lighting and Light Wires

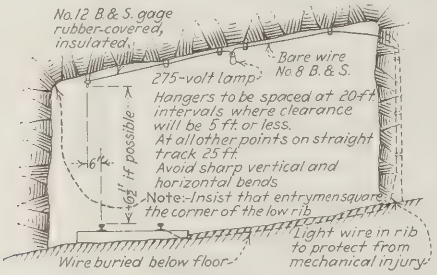
1. Electric lamps shall be installed at all partings, switches, passageways that cross haulageways, workrooms, pumps, hoist and motor-generator rooms, stables, transformer vaults and such other points as the mine foreman may direct.

2. Semi-portable lamps shall be fitted with rubber-clad cord (similar to Tirex), and the lamp shall be protected with a wire guard having wooden handle, similar to Western Electric Co.'s Catalog No. 2,590.

3. Lighting wires shall be attached to trolley or power lines by Universal test clip No. 27, which will permit of the circuit being disconnected while removing the base of a broken lamp.

4. All wiring shall be supported on porcelain insulators, and when the track is used as a return for the lighting circuits the return wire shall be attached to the track by bonding to the rail or by attachment to regular track bonds. (See Fig. 8.)

5. The ground connection shall be made of not less than No. 8 B. & S. gage copper wire which shall be buried below the surface of the floor and carried to the side of the entry and thence on porcelain insulators to the roof.



No. 12 B. & S. gage rubber-covered, insulated
Bare wire No. 8 B. & S.
275-volt lamp
Hangers to be spaced at 20-ft. intervals where clearance will be 5 ft. or less.
At all other points on straight track 25 ft.
Avoid sharp vertical and horizontal bends
Note:-Insist that entrymen square the corner of the low rib
6"
6½' if possible
Light wire in rib to protect from mechanical injury
Wire buried below floor

**Fig. 8—This Lessens Danger**

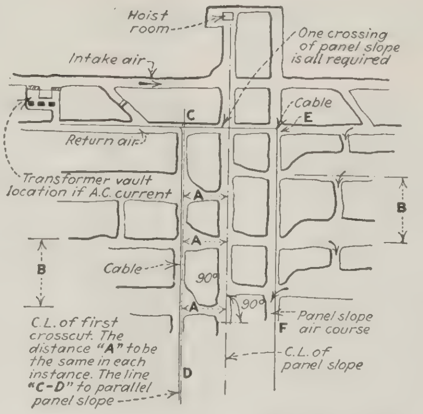
The haulage system of a mine is so important that it is worth while to install its feeder and trolley circuits in a safe manner.

6. All electric lamps connected to trolley lines for lighting underground shall be of 275-volt rating. Lamps supplied with alternating current shall be designed for 250 volts.

7. All sockets shall be of the keyless weatherproof type (similar to General Electric Catalog No. 60,666). Light wiring shall be not less than No. 12 B. & S. gage rubber covered and shall be supported on porcelain insulators or split knobs and held free from timbers, coal and rock.

8. Wires may be fastened to glass insulators, mounted on screw or wooden pins driven into the roof or the wire may be carried on a No. 3½ W. G. porcelain insulator fastened to timbers by means of ⅜x3½-in. lag screws with a ⅜-in. cut washer under the head.

9. Lamp bulbs shall be replaced only by the mine electrician or a person authorized by the mine foreman.



Hoist room

D
F
Panel slope air course
C.L. of panel slope

**Fig. 9—Simplification and Economy Go Hand in Hand**

This sketch shows a panel arrangement with the alignment of crosscuts on the opposite side of the slope from the air course, thus the necessity for cables on the slope is eliminated. With standardized room centers the cables *CD* and *EF* may be removed intact with supporting and controlling fixtures to any other panel.

10. In two-wire circuits, wherein one wire constitutes a permanently grounded return, this wire shall be installed in the same manner and afforded the same support and insulation as the live or supply wire.

11. All branch two-wire circuits leaving any main circuit shall be provided with a double-pole, fused switch of the safety inclosed type to protect the wires leading from it and for cutting off all current within the branch circuit.

### Cables and Power Lines

1. All power conductors shall be carried in manways or passageways that are ventilated by intake air. No wires or cables will be allowed in return air courses.

2. All wires or cables crossing slopes, panels or travelingways shall be carried underneath the road bed in a trough or in channels in the roof made to such a height as will render them safe from accidental contact.

3. For alternating current mining machine supply lines in panels 3-conductor rubber-insulated cable shall be used from transformers to room necks. This cable shall be supported by Fletcher mine wire holders, and shall terminate in suitable room switches at the room necks.

4. In panels the cable is to be carried in the passageway parallel to the panel slope. In the rooms on the opposite side of the panel slope, the first crosscut is to be driven parallel to the panel slope and at a standard distance from its center line, thus giving a passageway on both sides of the panel. This will eliminate the hazard of making numerous crossings over the slope with live cables. The same system will be observed where two-wire circuits supply mining machines. (See Fig. 9.)

5. All 2,200-volt power circuits leading underground shall be provided at the surface with a combination disconnecting switch and fuse in each conductor, capable of opening the circuit under load. Such switches must be provided with adequate lightning protection. (See Fig. 10.)

6. All 2,200-volt cables in damp or wet places, in boreholes or underground, shall be lead covered and armored or otherwise effectively protected from abrasion. The armor shall be electrically continuous throughout and shall be effectively grounded every 500 ft.

7. Buried cables shall be lead sheathed and armored or placed in metallic conduit.

8. In permanently dry mines the lead sheath may be omitted if the cable is provided with a rubber covering around all conductors and enclosed in a metallic armor to protect it against injury by abrasion.

9. Cables in entries or passageways shall be supported by cable rings on messenger wire and shall be electrically bonded thereto at intervals not

FIG. 10

**Protect All Cables**

Wherever 2,200-volt energy must be taken inside the mines each wire should be protected by a fuse and lightning arrester. Provision should also be made to open any or all of the line wires by means of a switch or group of single switches.

[*] This is the second of a series of articles giving the Code of Standards put into effect by the Union Pacific Coal Co., at its operations in Wyoming. The first article appeared in the Dec. 10 issue and the remainder of the code will be published in future issues in this form that permits of easy filing.

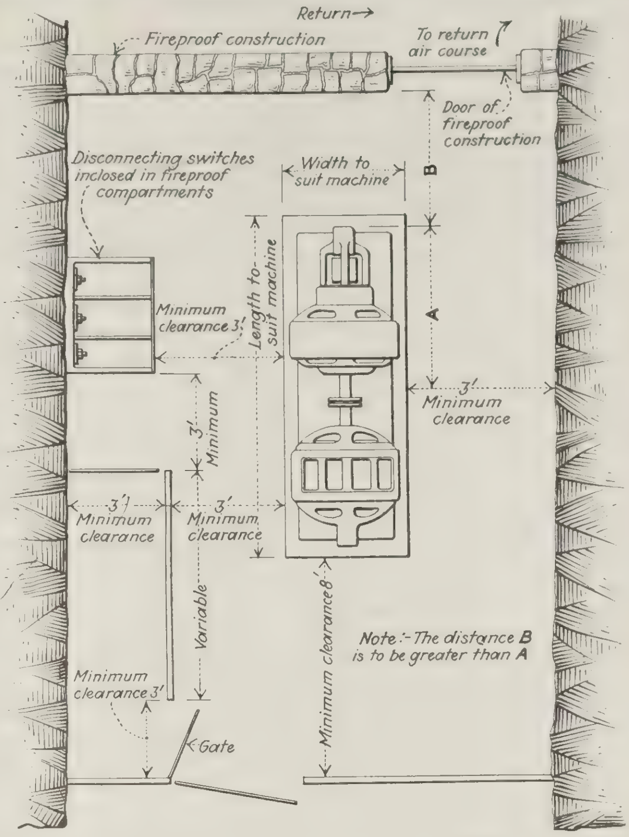

FIG. 11

**Elbow Room Makes Repairs Easier**

To provide adequate space for the operation and repair of substation equipment special consideration must be given to the arrangement of the machinery. The sketch shows the minimum clearances around the machine and circuit equipment also the design of the station with relation to air courses.

exceeding 500 ft. The supporting messenger shall be well grounded.

10. In future development all 2,200-volt cables shall be carried to a central distributing point and branch lines be provided with automatic oil circuit breakers.

11. Cast-iron tee boxes shall inclose connections where short lengths of 2,200-volt cables attach to main supply cables. These boxes shall be electrically bounded into the cable sheath circuit so that this circuit shall be electrically continuous between cables.

### Signal and Phone Lines

1. Telephone lines shall not be installed on the same side of an entry as power lines.

2. Every precaution shall be taken to prevent contact of telephone wires with power lines.

3. Telephone and signal lines between the mine openings and buildings shall be in underground conduit wherever there is possibility of their coming in contact with high-voltage lines through accident to either the high-voltage line or to the signal or phone line.

4. Telephone and signal lines must be kept apart from power lines.

5. Mine telephones to be of Western Electric Co.'s Type 1336J or its equivalent.

6. At points where wires enter the mine they shall be protected by a Western Electric Co.'s Type 58 A.P. protector installed in an iron box which must be effectively grounded.

7. Telephone wires shall be iron, No. 12 Birmingham wire gage, rubber covered and shall be supported in the same manner as low-voltage power lines.

8. All slope signal wires shall be No. 8 Birmingham W. G. or its equivalent, and shall carry not more than 30 volts.

9. Supports for slope signal wires shall not be more than 25 ft. apart and the space between wires shall be 6 in. All wires must be drawn taut and extend the full length of the slope.

10. On main slopes over 1,000 ft. in length duplicate signal wires shall be installed.

### Rules for Wiring Underground Stations

The following rules include such places as in hoist, pump and motor-generator set stations, stables, repair rooms, mine foremen's cabins, toolrooms, etc.

1. Wiring for lights shall be installed in metal conduit.

2. Each room shall be provided with a safety type of entrance switch.

3. Wire shall not be smaller than No. 12 B. & S. gage, and shall be rubber covered.

4. Ceiling lights shall be in fixed positions.

5. Receptacles shall be installed on opposite sides of the room for attaching semi-portable lamps where necessary.

6. Not more than six lights shall be installed on any one circuit.

7. All conduit shall be grounded.

8. Rooms containing motor-generator sets, pumps or hoists shall be ventilated with intake air at all times, and shall be located between intake and return air courses in order that fumes or smoke given off at times of burnouts may be diverted to the return air course.

9. Cables leading to motors and particularly those remotely situated from other points of disconnection shall be provided with expulsion type cutouts (General Electric Catalog No. 106,918 or its equivalent.)

10. No wiring for lights shall be carried within 5 ft. of any temporary powder storage room.

### Hoists

1. Permanent hoist rooms are to be fireproofed, in a manner determined by the general superintendent. (Temporary locations are those wherein the machine will be in service in one position less than 6 months.)

2. Hoist motor, controller, control equipment, oil switches, cable sheaths, current, potential, power and lighting transformers, switchboard frames, resistance boxes, and supporting frames, shall be grounded as heretofore provided.

3. Resistors shall be mounted on concrete bases or supported on pipe frameworks so that the bottom of the resistor will be at least one foot from the floor and shall be 24 in. removed from the coal rib so as not to present a fire hazard.

4. Resistors shall be protected with a suitable inclosure.

5. Control wiring, unless installed in metal conduit, shall have slow-burning insulation. All conductors composing such wiring shall be so laid that they may be readily traced and identified.

6. Wires connecting resistors and controllers or controller panels shall have slow-burning insulation. Wiring between motors and liquid controllers shall have rubber insulation.

7. Plans shall be developed for each district so that each hoist together with its complement of conduits, wires, cables, guards, floorplates, etc., may be removed in their entirety to new locations.

8. Primary contactor panels carrying 2,200 volts shall have all live parts completely inclosed in a box of transite or asbestos board.

### Motor-Generator Set Rooms

1. For general arrangement of motor-generator set rooms see Fig. 11.

2. Special attention shall be paid to location relative to load center in order that power may be distributed in two or more directions.

3. Ample space shall be provided around the apparatus to permit easy handling in case of dismantling for repairs.

### Switchboards

1. All switchboard frames are to be made of pipe or other metal supports with panels of incombustible material possessing insulating qualities suitable for the voltage carried.

2. Switchboards shall be given a 3-ft. clearance at the front, back and ends. Panel boards shall have a clearance of 2 ft. from the floor.

3. When the potential behind the switchboards exceeds 275 volts, the rear of the board shall be protected by gates and marked by appropriate signs.

4. All switchboard mountings, instruments, transformers and instrument casings shall be grounded.

5. Conductors shall not cross the passageways back of switchboards except below the floor or at a height of at least 6½ ft. above the floor.

# Book Review

## What Can Be Done to Give Steady Employment?

Unemployment and the methods by which employers are endeavoring to eliminate irregularities of operation is covered briefly, yet compendiously in "The Regulation of Employment, A Study in the Prevention of Unemployment," by H. Feldman, assistant professor, industrial relations, Amos Tuck School of Administration and Finance. The researches into the seasonality of the coal business are bearing fruit in an examination of other industries which had hitherto escaped investigation mainly because their inequalities of operation had not been made the basis of a persistent campaign by union leaders or the subject of a study by a compiler as sedulous as the U. S. Geological Survey. The evidence of the need for a "regularization" of industry is strongly set forth in this volume by Mr. Feldman, and any one who reads it will be convinced that the coal industry is not the sole and, possibly, not the most grievous offender. The book contains 437 pp., is 5½x8½ in. in size and is published by Harper Bros., New York City. The price is $3.50.

### MANY INDUSTRIES HAVE "OFF" SEASONS

"In a recent study of printing," says the author, "one plant is cited which employs 2,700 persons in rush seasons and drops off to 1,500 in dull; another which lays off 1,100 employees for periods of three months twice a year, therefore having a fluctuating payroll varying from 1,800 employees to 700 employees. Census figures for the United States sugar industry in 1919 show 4,661 persons employed in March and 27,064 in November." And again, "One plant situated in a great fruit and vegetable packing state and working on a seasonal basis, usually began work with a full force of 1,200 men, women and children, working sixty hours per week for several months. At the end of August or perhaps at the end of September, the force was suddenly reduced to as few as 100 employees." And yet, again, "A manufacturer of household specialties made 1,500 articles, which though staples, showed surprising seasonal variations in demand. The total sales of the firm for the four quarters of the year were approximately 20,000 lb., 8,000 lb., 10,000 lb. and 30,000 lb. respectively."

Coal gets its appropriate space in this volume and is well treated, though we would question if it is safe to say that, "Fortunately it is now known that coal can be stored safely and economically," even though the writer adds "types known to be particularly liable to spontaneous combustion should not be selected." He declares that "communities should aid the smaller consumers by providing municipal storage facilities." This seems to be a matter for private enterprise. It must, however, add greatly to the cost of the coal either by reason of high land rents if stored conveniently, or by reason of high truckage costs if stored where land is cheap.

"One trouble of this [bituminous] trade," says Mr. Feldman, "is the failure of bituminous operators to get together on their industrial problems." He overlooks the obvious fact that the law forbids such getting together and not wholly without reason.

## Water Gage or Anemometer to Show Entry Falls?

In the issue of *Coal Age* dated Oct. 8, covering the meeting of the Southern Mining Co.'s engineers at Williamsburg, Ky., a brief paragraph, referring to a paper which I read before them, states that "He [C. H. Trik] explained the fallacy of depending on the water-gage reading at the fan to indicate the condition of the airways. The anemometer is the only instrument which tells the true story."

This is only half of what I said, and it makes it appear that I recommended the disregarding of water-gage readings in favor of the use of the anemometer as an index of the condition of the mine. This was not my intention, for, indeed, the water gage is the most important instrument the mine ventilation engineer has in his determination of all ventilation characteristics of a mine.

### EXPLAINS FULL MEANING

What I hoped to make clear was that it was useless to depend on a water-gage reading taken at the fan to tell whether there had been a fall of top in the air courses during the night. I explained that a modern fan running at a constant speed produces a constant depression and, therefore, providing the ventilating unit was not working above its normal capacity, any change in the aircourse such as a fall in top, would not be indicated on a water gage. It was at this point that I said the proper instrument to use to obtain such information would be the anemometer rather than the water gage.

The mine foreman is usually well conversant with the volumes flowing through his mine and any falls in the aircourses would, of course, tend to reduce the sectional area, and naturally, with the fan running at a constant speed, reduce the volume being handled. For this determination the anemometer is the instrument to use.

C. H. TRIK,
Ventilation Department
Jeffrey Manufacturing Co.,
Columbus, Ohio.

## Washington Has Deeper Mine

On page 531 of the October issue of *Coal Age*, I note a statement to the effect that the Auchincloss No. 1 shaft of the Glen Alden Coal Co. near Nanticoke, Luzerne County, Pa., is the deepest coal mine in America.

I believe the record for the deepest coal mine in the United States goes to the famous Black Diamond Mine at Black Diamond, Wash., 30 miles southeast of Seattle. This mine has a depth below the surface of 2,049.34 ft. and below sea level 1,491.34 ft. You can see from these figures that it is under a cover 351.94 ft. greater and is 538.34 ft. deeper below sea level than the anthracite mine to which you refer.

GEO. WATKIN EVANS,
Consulting Engineer.
Seattle, Wash.

# News Of the Industry

## Hard-Coal Peace Plans Plentiful; Union Leaders Refuse to Consider Anything but Pinchot's Proposals

Prospects of an early resumption of mining in the hard coal region appeared nearly as remote as ever at the opening of Christmas week. The only thread of hope, and that admittedly a slender one, was the campaign undertaken by mayors and burgesses of the anthracite communities to bring the operators and miners together again to resume negotiations. This campaign was started after the civic officials, summoned to Harrisburg on Dec. 16, had declined to be bound by the Pinchot "peace" plan in their efforts to persuade the scale committees to reopen discussion. The Harrisburg conference went on record in favor of any plan that would break the deadlock in the following resolution:

"That it is the sense of this meeting of the executives of the anthracite region that the operators and miners be invited to meet together in conference at the City Hall of Scranton one week from today or at such other time and place as may be more convenient, there to take up the negotiations at the point where they were broken off last August and with the understanding that either side shall be at liberty to bring up for discussion its own plan or plans, the Governor's plan or any other plan that may be offered."

The operators, meeting at Wilkes-Barre on Sunday, announced their acceptance of the invitation to meet the miners under the terms of that resolution, which, they pointed out, "indicates that no one plan is to be the subject of conferences, but that any plan may be presented for consideration. With this understanding we accept your invitation.

"If the miners likewise accept your invitation under the conditions stated in your resolution, then we are ready to meet at the call of the chairman, Alvan Markle, as provided in the resolution of the negotiating committees adopted at the time of adjournment at Atlantic City. This is the regular course of procedure in such cases. If the published report of Mr. Lewis' reply to your communication is correct that the Pinchot plan alone will be considered by the miners, it would, of course, preclude a conference."

At the time the operators' position was made public, no formal statement of the miners' stand had been made. It was strongly intimated, however, that Mr. Lewis and his associates would insist that the Pinchot plan alone be the basis of negotiations.

The war of words over the causes for the failure to end the authracite suspension grew increasingly violent during the past week. A five-point program to end the strike, suggested by seven Luzerne County members of the Pennsylvania House of Representatives and promptly indorsed by the operators, moved John L. Lewis, president of the United Mine Workers, to a fresh outburst of belligerency. He denounced the proposals as "simply the operators' plan wrapped up in a new package," charged the producers with a conspiracy to smash the union and declared that "the United Mine Workers is now organizing the defense of the anthracite mine workers in expectation of a continuance of the present struggle to the fall of 1926 or the spring of 1927."

W. W. Inglis, chairman of the operators' negotiating committee, retorted with an attack upon the figures used by Mr. Lewis in building up the "conspiracy" charge. Between 1902 and the time Mr. Lewis assumed control of the union, said Major Inglis, differences between the operators and the men had been settled by collective bargaining. "Since Mr. Lewis has been in charge, nothing has been accomplished by that process and we have had three strikes in less than four years.

### Bituminous Leading Influence

"Mr. Lewis glibly talks about continuing the present struggle to the fall of 1926 or the spring of 1927. Once more he furnishes evidence of the interest of his organization in the bituminous field. The anthracite strike had its beginning in Mr. Lewis' effort to regain lost ground in the bituminous field. When he talks of continuing it to the expiration of the Jacksonville agreement, it is apparent that the dominating influence in the present controversy is still bituminous and not anthracite."

Governor Pinchot's activities came in for a scoring from two sources. The board of directors of the Chamber of Commerce of the United States, meeting in Washington, adopted a resolution stating that "examination of his proposal shows that it did not propose that all controversial issues should be arbitrated. On the other hand, the operators offered arbitration of all issues involved in the controversy. While it is not the purpose of the board to define any plan of arbitration, it is its judgment that any plan to be of lasting benefit to the industry and in the public interest should consider the merits of the controversy in all of its aspects."

### *Why Worry About Strike? Heat Homes with Mine Gas*

Capturing escaping mine gas and piping it into their homes in Kirby Park, Wilkes-Barre, Pa., Tom Phillips, supervisor of the parks in that city, and William Law, foreman at Kirby Park, have solved the fuel problem as far as they are concerned. The supply of gas has been led into the fireboxes of hot air furnaces, where crushed bricks were placed and the gas ignited. The burning gas heats the broken brick to a white heat and the radiation is more than sufficient to heat the homes comfortably. There appears to be sufficient gas from this one source to heat fifty homes, and other householders in the vicinity of the park are talking of adopting the same plan. It sounds like a fairly tale, but the two park officials say "let those who doubt come and see." It is admitted that the supply is uncertain, however, inasmuch as mine gas frequently disappears rather suddenly.

The second attack upon the Pinchot program came from the operators in a lengthy statement made public on Dec. 18. Instead of taking the middle ground alleged, said the statement, the Governor's proposal "resolved every question in the miners' favor without investigation. The Governor criticizes the operators because they have refused 'to yield one jot or tittle of their orginal position.' The truth is that the operators have made certain assertions of fact which they believe to be true. If the assertions of the operators are untrue and do not afford the basis for a sound and fair settlement, that would be brought out in the kind of impartial arbitration for which the operators have been contending from the start.

"Neither the Governor's plan nor the calling of an extra session, nor condemnation of the course taken by the operators produces any coal. The operators have had a single aim throughout the entire controversy. That was to bring about production, avoid suspen-

# *Real Earnings of Contract Miners In Anthracite Fields—II*

(Lehigh Coal & Navigation Co.)

Are contract miners in the anthracite fields underpaid?

John L. Lewis, international president of the United Mine Workers, insists that they are. He has repeatedly drawn upon the reports of the Coal Commission, with their misleading figures basing earnings upon the number of starts made, to support his assertion. In a statement published in the Sept. 15 issue of the *United Mine Workers' Journal*, Mr. Lewis declared that the average was $1,700 per year, from which "there must be deducted over $200" for supplies.

Check of actual payrolls, however, tells a far different story.

For example, in 1924, six breakers of the Lehigh Coal & Navigation Co. averaged 271 starts per breaker and employed 1,638 contract miners. But only 1,136 men, or 69.4 per cent, of the total worked regularly enough to appear on each of the 24 semi-monthly payrolls. There were 152 men who earned over $3,500 *net* for their work. This group, averaging $3,809.78, made 274.8 starts, or an average of 3.8 days more than the average starts per breaker. The next highest compensated group averaged 268.4 starts, as compared with 271 for the breakers, and made $3,448.53.

The average earnings by $100 groups for the 1,136 contract miners were as follows:

| Miners | Average Annual Earnings | Miners | Average Annual Earnings |
|---|---|---|---|
| 152 | $3,809 | 80 | $2,451 |
| 39 | 3,448 | 70 | 2,353 |
| 46 | 3,347 | 57 | 2,246 |
| 40 | 3,241 | 53 | 2,152 |
| 38 | 3,150 | 33 | 2,056 |
| 68 | 3,051 | 22 | 1,953 |
| 80 | 2,949 | 17 | 1,849 |
| 90 | 2,850 | 9 | 1,749 |
| 82 | 2,748 | 1 | 1,630 |
| 82 | 2,650 | 3 | 1,562 |
| 74 | 2,547 | .. | .... |

The average per man for the entire group was $2,830.54. Nearly 70 per cent (69.63) of the group averaged in excess of $2,500 per annum. Less than 5 per cent received under $2,000. The three men in the lowest rated group ($1,562 per annum) worked only 225 days.

---

sions in the future, and, if possible, reduce prices to the consumer. Any plan that does not accomplish permanent peace is valueless.

"The only practical effect of the Governor's course is to prolong the strike, increase the public's inconvenience and add to the distress suffered by the mine workers and to the losses of the industry and to the whole anthracite region."

The Luzerne County legislators' plan so hotly dismissed as unworthy of attention by the miners provided:

(1) An immediate resumption of work under the terms of the expired contract for the period until Sept. 1, 1926.

(2) A negotiating committee to be composed of three representatives of the operators and three representatives of the mine workers to resume negotiations two months after the resumption of work, to consider any modifications of the expired contract that may be urged by either party.

(3) In the event that any matters in dispute are not disposed of by the negotiating committee within thirty days after the resumption of negotiations, such matters shall be referred to a board of settlement, to be composed of the members of the negotiating committee, who shall sit with the board of settlement but without vote, and five voting members to be appointed to represent the public interest either by, first, the President of the United States, or, as an alternative, by, second, the Chief Justice of the Supreme Court of Pennsylvania and the presiding Judge of the U. S. Circuit Court of Appeals of the Third Circuit. This board of settlement to have authority to start immediately an investigation of the economic and technical facts by which all questions of working conditions, wages, etc., may be settled. The board to be selected and organized within thirty days after any questions are referred to it, and to render its decision within three months.

(4) A new contract embodying the above principles, for a period of at least five years and preferably for ten years, to be formulated and signed to be made effective from September, 1925.

(5) Either party to have the right, not oftener than every twelve months, to call a conference of the negotiating committee to reconsider any element of the contract. Matters not disposed of within sixty days at such conference to be referred to the board of settlement for final decision, such decision to be rendered within sixty days of such reference.

The Chamber of Commerce resolution was not the only Washington expression on the strike situation. On Dec. 17 Senator Copeland of New York asked the Senate to forego its holiday recess until something was done to relieve "suffering of the poor forced to go out each morning for a bucket of coal just as they do for a bottle of milk or a loaf of bread." On Dec. 19 Representative Black of New York attacked President Coolidge for failure to intervene. The President's policy was defended by Representative Treadway of Massachusetts, who urged consideration of coal regulatory bills he has introduced. One of these bills authorizes the President to operate the mines in emergencies and another measure would put the Coal Commission's recommendations on the statute books.

On Sunday night the American Federation of Labor made an appeal to union workers in other industries to come to the financial support of the striking miners. The strikers were pictured as victims in a struggle against "arrogant" operators for the rights of union labor. The burden of meeting the necessities of unemployed members and their families in both anthracite and bituminous fields, said the appeal, "is too great for one organization and the cry reaches beyond the United Mine Workers of America. Organized labor in America must hear that cry, and, hearing it, must respond to the needs of the men, women and children in the anthracite region who are suffering from hunger and who need our help."

---

## Sue Arkansas Union on Basis Of Coronado Case

The Greenwood Coal Co., Mammoth Vein Colliery Co., Backbone Coal Co., Semi-Anthracite Coal Co. and Blue Hills Coal Co. filed suit in the U. S. Court at Fort Smith, Ark., Dec. 11, against District 21, United Mine Workers; its officers, executive board, individual members and locals in western Arkansas counties, alleging conspiracy to restrain commerce in coal and praying judgment for $1,080,000 as triple damages under the Sherman Anti-Trust law.

The suit is based on the same contentions made in the suit of the Coronado Coal Co., now on trial for the third time in U. S. District Court.

Miners now on strike are charged with having caused employees of the companies to quit work by threatening them and by other methods and with advocating violence during union meetings in violation of an injunction order issued by the Sebastian County Chancery Court and with responsibility for the burning of the tipple of one mine.

The alleged combination also is charged with maintaining agents and representatives charged with the duty of preventing, if possible, the transportation of coal in interstate trade and commerce.

---

## Free Reconsignment Allowed By Grand Trunk at Detroit

The following provision in Grand Trunk R.R. I.C.C. 2272, Suplement 2, became effective Dec. 2, 1925:

"No charge will be made for a single diversion or reconsignment of anthracite coal when reconsigned or diverted at Detroit, Milwaukee Junction or West Detroit, Mich., for deliveries within the Detroit switching district or when destined to points beyond the Detroit, Milwaukee Junction and West Detroit switching district when through rates from points of origin or rate basing point to final destination apply via Detroit, Mich.

"No charge will be made for a single diversion or reconsignment of anthracite coal when reconsigned or diverted at Port Huron, Mich., for deliveries within the Port Huron (Mich.) switching district, or when destined to points beyond the Port Huron switching district when through rates from points of origin or rate basing point to final destination apply via Port Huron."

---

## *Orient No. 2 Produces 12,823 Tons in Day*

Orient No. 2, the Chicago, Wilmington & Franklin Coal Co.'s big mine at West Frankfort, Ill., established a new world's record on Dec. 17 by producing 12,823 tons of coal. This was the third time within three months that this operation broke the world's record for a single day's production.

This immense output required 248 railroad cars. The mine's previous record was 11,325 tons. Eleven hundred miners are employed.

# Coolidge Luck Seen in Diversion Of Anthracite Strike to Intrastate Issue by Pinchot Call to Legislature

**By Paul Wooton**

Washington Correspondent of *Coal Age*

Whether or not the Governor of Pennsylvania will succeed in curbing his pet obsession, the "anthracite monopoly," at the special session of the Legislature which he has called, remains to be seen, but he has done one thing: he has created a diversion which removes the anthracite situation from national politics. It now has become an intrastate issue. So long as the executive of a sovereign state which includes all of the anthracite mines is acting the federal administration will have less reason than ever to intervene.

Governor Pinchot has the police power and all of the mines are in his bailiwick. He has drawn to himself the spotlight of public attention and has furnished the President with a second and a better reason than the presence of Congress for declining to interfere. Some see in this another manifestation of Coolidge luck.

Even Congress is less likely to act until at least the Pennsylvania Legislature shall have had an opportunity to meet the situation. As far as constitutional powers to control either miners or operators are concerned, the state Legislature has two trumps for each one held by Congress. Speculation in Washington turns on what the Governor can accomplish through the medium of the Legislature.

### See Tough Job for Pinchot

Pennsylvania politics is little understood in Washington, so the comment does not get much beyond questions. Doubt is expressed as to the ability of the Governor to force the Legislature to take any action against the anthracite operators. Pennsylvania is a conservative state. Its legislators have a better grasp on sound business principles than is the case in many other states. In the national Congress the anthracite industry might have few champions, but in the Pennsylvania Legislature there is no dearth of capable members who will see that the position of the producers is presented effectively.

Doubt is expressed, however, of the willingness of the Legislature to punish the miners. The often repeated suggestion that the contract miners' certificate law be repealed seems to lose sight of the fact that this law was passed in the days of Boss Quay, before the union entered the anthracite region. Enough is known in Washington of the situation in Pennsylvania to realize that the chance of erasing that law from the statute books is small.

Whatever the Legislature may do the feeling in Washington is that Governor Pinchot and John L. Lewis, between them, have so muddied the waters as to confuse the public further. The call of the Legislature tends to strengthen the impression that the miners already have spread abroad that there is a desire to avoid the issue rather than take action calculated to terminate the strike promptly.

The Board of Directors of the Chamber of Commerce of the United States was prompted by the action of the Pennsylvania Governor to adopt a formal resolution in the following language:

"Arbitration as a means of adjusting the present strike in the anthracite field has taken on added importance because of the proposal of Governor Pinchot.

"An examination of his proposal shows that it did not propose that all controversial issues should be arbitrated. On the other hand, the operators offered arbitration of all issues involved in the controversy.

"While it is not the purpose of the Board to define any plan of arbitration, it is its judgment that any plan, to be of lasting benefit to the industry and in the public interest, should consider the merits of the controversy in all of its aspects."

None will be surprised if there is administration support for fact-finding legislation. This support will be predicated on a belief that the coal industry could be made more helpful with a complete statistical service. It is thoroughly recognized that the industry will oppose such legislation. The feeling is, however, that only government figures would be accepted by the public. Even were the industry itself to furnish the figures that would be thoroughly satisfactory to the government, the opinion is expressed that the public would not have confidence in the statistical returns from that source.

### Adequate Statistics Needed

In that connection the opinion is expressed by those holding these views that had the government been furnishing an adequate statistical service on coal, regulation of the industry could have been withstood more successfully at this session. Even now the feeling in these quarters is that a real coal statistical service by the government would constitute great protection to the industry from more savage forms of legislation.

Despite the inherent tendency of Anglo-Saxon peoples to oppose monopoly, the opinion is expressed that public sentiment would not be averse to the reduction of producing units in the coal industry from eight or nine thousand to five or six hundred. The feeling is that with this latter number of units, ample competition would be insured and the industry would be stabilized greatly.

## *Strike Effects Stressed in President's Message*

Referring to strikes, President Coolidge in his message to Congress, on Dec. 8, said:

"A strike in modern industry has many of the aspects of war in the modern world. It injures labor and it injures capital. If the industry involved is a basic one, it reduces the necessary economic surplus and, increasing the cost of living, it injures the economic welfare and general comfort of the whole people. It also involves a deeper cost. It tends to embitter and divide the community into warring classes and thus weakens the unity and power of our national life. Labor can make no permanent gains at the cost of the general welfare."

# C. Bascom Slemp Heads New $9,750,000 Merger Of 14 Coal Companies

Richmond, Va., Dec. 19.—A charter was granted today to the Wakenva Coal Co., which represents a consolidation of fourteen coal mining companies. The production of the fourteen mines of these companies, located in West Virginia, Kentucky and Virginia (from the names of which states it will be observed that the name of the new company is derived), is 1,500,000 tons annually. It is expected that the output will be increased to 2,500,000 tons, which will make the company one of the most important operating units in the Southern fields. The total capitalization is $9,750,000. The financing was arranged through Robert Garrett & Sons, Baltimore.

C. Bascom Slemp, who, upon his retirement as secretary to President Coolidge, resumed the practice of law with offices in Washington, D. C., is the Chairman of the Board of Directors of the new company; S. R. Jennings, Johnson City, Tenn., who headed a number of the constituent companies, is president of the new organization, and A. S. Higginbotham, Tazewell, Va., vice-president. The directors include C. B. Slemp, S. R. Jennings, Jas. W. Gerow, A. K. Morison, E. R. Boyd, A. S. Higginbotham, Ferdinand Powell and other prominent business men.

The markets will be in the South, along the Atlantic Seaboard and in the Northwest. It is stated that the company will sell high-grade domestic and steam coals.

The companies included in the merger are the Beaver Creek Coal Co., Camp Branch Coal Corp., Floyd-Elkhorn Consolidated Collieries, Graden Coal Co., Hazard-Blue Grass Coal Corp., Hill Creek Coal Co., Kennedy Coal Corp., Kroll-Litz Coal Co., Lewis Creek-Banner Co., Nora Coal Corp., Sandy Ridge Coal Co., Upper Banner Coal Corp., Virginia-Banner Coal Corp. and Walkers Branch Mining Co.

## Labor Now Minor Factor In W. Va. Strike Zone; Selling Problem Presses

The labor situation does not seem to be an important factor in northern West Virginia at present as far as coal production goes. The non-union mines seem to be getting out all the coal they want and a great deal more than the present flabby market will absorb. There were rumors afloat in the region this week to the effect that the non-union operators will make another reduction in wages after Jan. 1. As no intimation of such a move has been made public thus far, it is thought to be union propaganda.

Some operators believe that an effort should be made to effect a number of group mergers, which would take away the stigma of monopolistic features and at the same time pave the way toward stabilization. Central sales agencies also are suggested as a means of solving many of the unwholesome business problems of the industry. While the operators unquestionably have won the laurels from the United Mine Workers in their labor struggle it has been a costly fight and with the present ragged market and no hopes of curtailing production they are beginning to find that not a great deal has been gained in dollars and cents. Many companies have borrowed heavily on their properties, and officials say they have little to show for their struggle. If the present unsettled market continues some of the companies may be forced into bankruptcy.

With the approach of the Christmas season production in the region is easing up; a number of mines in the field, it is said, will close down over the holiday season.

### B. & O. Embargo Placed

Due to the heavy bituminous coal shipments in the East the B. & O. placed an embargo on consignments to Reading, Pa., at the request of the Reading Ry. The mines had a full run of coal cars last week, after car shortage was experienced on the Monongah Division, B. & O., during the last three days of the previous week. Pennsylvania equipment on the Monongahela was getting scarcer toward the end of the week.

Two hundred and twenty-four non-union coal mines are operating daily in the 12½ counties of northern West Virginia, while the average number of union mines at work in the region is 14. After a lull of some time the first union mine on the Monongah Division, B. & O., resumed operation last week. This is the Annabelle Mine of the Four State Coal Co., near Worthington.

In the first half of last week the mines of the 12½ counties loaded 5,688 cars of coal, compared to 6,051 cars in the corresponding period of the previous week. Union mines loaded 784 cars of coal in the first four days of last week compared to 862 cars in a similar period of the previous week.

The Mine Workers continue their mass meetings in the field, although they are not as numerous as some weeks ago, when the weather was milder. Officials say 600 people attended a meeting at Bear Mountain Dec. 13 and that meetings addressed by Bittner in Philippi and Rosemont Dec. 15 were well attended, as was a meeting in Flemington Dec. 16. A large mass meeting was held in Scott's Run Dec. 13, also. Group meetings of local unions were held last week in Monongah and Farmington and the regular session of the policy committee was held in Monongah.

Robert Bostic, a union miner, was shot at Bingamon, a mining town of the Bingamon Gas Coal Co., Dec. 13, by Marion B. Shobe, a mine guard, it is alleged, and Bostic is a patient in St. Mary's Hospital in Clarksburg suffering from two wounds in the back.

**Major Clarence T. Starr**

He is coal specialist for the Chamber of Commerce of the United States and has been elected chairman of the Washington section of the American Institute of Mining & Metallurgical Engineers. M. Van Siclen, assistant chief mining engineer for the Bureau of Mines, was elected vice-chairman. H. I. Smith, chief of Minerals Leasing Division of the U. S. Geological Survey, was chosen for the combined office of secretary and treasurer. J. D. Nevius, of the Mines Valuation section of the Bureau of Internal Revenue, and W. H. Wagner, a consulting mining engineer, were elected to form, with the foregoing, an executive committee.

## *Modify Union Wage Scale In Cambridge Field*

After a conference of several weeks between leading operators in the Cambridge (Ohio) field and representatives of the United Mine Workers, an agreement was reached last week to modify local conditions in the Jacksonville scale in such a way as to reduce production costs. The miners waived their claim for payment for removing slate, and changes were made in the rules governing the width of entries to be driven. All the operators signed the new agreement except the National Coal Co. and the Cambridge Collieries Co., the two largest operators in the field. It is believed that some of the mines will resume work on the modified scale.

## Dering Mine Reopens; Will Comply with Indiana Law

Work was resumed Dec. 10 at the Dering mine No. 6, in the Clinton field, Indiana, following dissolution of an injunction granted by Judge Howard Maxwell of the Parke County Circuit Court, restraining the state mine inspector from interference with the single-entry system of mining practiced in the mine. Points of controversy in the case, which attracted wide attention in Indiana mining circles because of the principles involved, were settled by an arbitration board. Miners refused to return to work, however, until the injunction was dissolved. This was accomplished through application to the court by attorneys representing the J. K. Dering Coal Co., owners of the mine, and the miners.

Previous to issuance of the injunction the company had used machines in working single entries, obtaining ventilation through an auxiliary fan that forced air to the working face through a canvas tube. No "breakthroughs," as provided for in the state mining law, were employed. Following protests by the miners, an inspection was made by the state mine inspector. The Dering company countered this move by obtaining the injunction. The miners walked out.

With the reopening of the mine a double-entry system with "breakthroughs" for ventilation will be used.

## High-Volatile Supplemental Rate Order Extended

Through the activities of A. A. R. Yarborough, traffic manager of the Kanawha Operators Association, the original supplemental order of the Interstate Commerce Commission granting joint through rates on high-volatile prepared coal from southern West Virginia has been amended to include mines along the New York Central (Kanawha & Michigan) on the north side of the Kanawha River. The order now extends to all mines on the Winifrede R.R., Kanawha Central R.R. and all mines in the Kanawha district at points on the New York Central lines, from Plymouth to Gauley bridge, including points on the Smithers Creek branch, and all rates on the prescribed basis will be maintained as follows: New York Central lines to all destinations embraced in routes 1 to 41 as prescribed in original supplemental order. The rates upon the basis prescribed in the supplemental order issued are to become effective on or before Jan. 4, 1926, upon not less than five days' notice and in every other respect shall accord with orders laid down in supplemental orders affecting other bases in the Kanawha field.

---

Coal operators received word in Fairmont, W. Va., Dec. 16 that the Interstate Commerce Commission has granted permission to the Baltimore & Ohio R.R., to change the tariff so as to eliminate the $2.70 charge on "order-notify" shipments, which was protested by the Monongahela Valley Association at its meeting in Fairmont Dec. 15.

## Machinery Set in Motion To Block Intrusion of Government in Business

Steps to curtail the intrusion by government in private business were taken at a two-day conference of about two hundred representatives of business, trade and other organizations concerned in the growing tendency of municipal, county, state and federal governments to engage in business activities held to be the proper province of the citizen, which concluded its sessions at Washington on Dec. 11.

It was the definite expression of the conference that no new organization was necessary, but that it was advisable to create a conference committee to aid the activities of the associations interested in this particular subject.

The declared purpose of the conference was:

"(A) To disseminate among the people correct information as to the extent, cost and results of government enterprises.

"(B) To urge that in all government operations there be established a recognized and adequate system of cost accounting; and that all existing prohibitions against rewarding labor on merit and efficiency be abandoned.

"(C) To inform the people that government in business means the establishment of a socialistic state, and the ultimate destruction of all individual opportunity.

"(D) To oppose every existing or proposed intrusion by government into the proper field of private enterprise."

### Hoover Foresees Difficulty

Getting the government out of business is more difficult than it appears on the surface, Secretary Hoover pointed out in an address at the conference.

"It seems to me that you will have a good deal of difficulty establishing any very precise lines of principles on the question of the government in business," he said. "And one side light on it is that the demands that the government shall get into business to large degree come from the business world itself. The desire to regulate the other fellow seems inherent in the human heart. Therefore an education of the business world will be useful as a start on the question.

"Nor is it possible to dismiss the question with just the summary slogan of 'Get the Government out of Business.'

"To start with, it is obviously the proper function of all government to prevent fraud and unfair practice in business. The ten commandments need some supplement to meet new inventions. The steady growth of business standards and business ethics has been a solid contribution of progress in this direction.

"Furthermore, uncontrolled monopolies have been anathema to the sense of the race ever since Cromwell, and we all look to the government to take care of the question. Some years ago we strengthened the anti-monopoly laws by the Sherman Act, under which it was proposed to maintain competition in all directions. The people gradually came to realize that the public utilities were a national monopoly in the local sense and that maintained competition among them would entail enormous duplication of capital and service and consequent cost to the consumer. With good sense they have set up monopoly but subject to regulation. So we have the government in the business of regulating the profits of the natural monopolies and the government in the business of and insisting upon competition among the other industries and trades. It may not be done perfectly, but in any event, it is not going to be abolished. It ought to be made better.

"Again there are numbers of public-works, river and harbor road and other improvements which by common consent must be built on at government expense.

### Unnecessary Duplication Costly

"There are a vast amount of welfare services such as educational and statistical services, informational services, promotion work which have been established in the government by common consent, all of which mean much government in business. In all this governmental machinery we need much reorganization not only that it shall work more efficiently and economically but that its unnecessary duplications shall be taken off of the back of the people.

"But what I feel that most people refer to when they talk of the government in business is that they do not wish the federal government to engage itself in the buying of commodities, or services for resale, and they do want the government to procure services and commodities for its own use by competitive bidding from the business world.

"I believe there are some points where the federal government could reduce its business activities. I am sure the whole federal government and Congress would welcome a sane study of the whole problem. Government officials are overburdened with labor and they welcome the co-operation and development ideas and methods, and eternal vigilance is the price of liberty in these matters."

## *Not Liable for Injury to Child Hired "on Quiet"*

The Kentucky Court of Appeals on Dec. 11 rendered a decision holding that under the Kentucky child labor law an employer cannot be held liable for damages when a child is injured who has been employed without the knowledge or consent of the employer. In this case a 13-year old boy who had been killed in a fall from a company truck had not been employed by the company but by the company's truck driver, who was getting the boy to help him. Counsel for the defense successfully maintained that contributory negligence of the boy's parents in permitting his employment was a proper defense to the action against the company.

## Act to Set in Motion Hoover Anti-Waste Plan In Marketing Methods

Acting in accordance with a suggestion from Secretary of Commerce Hoover, the National Distribution Conference, meeting at Washington under the auspices of the United States Chamber of Commerce, on Dec. 16, took steps toward setting up machinery by which business may co-operate for the purpose of self-government and the tracing and elimination of wastes in marketing. The conference began Dec. 15 and lasted two days.

In the early sessions of the day committee reports were submitted describing marketing conditions as they now exist. The reports placed the blame for marketing wastes with the producer and the consumer, as well as with the distributor. The conference subsequently decided that "present methods of distribution have been developed by economic forces and fundamentally are sound."

The conference recommended as a first step toward the elimination of trade abuses and destructive trade practices that the Chamber of Commerce designate a joint trade relations committee, representing manufacturers, wholesalers, retailers and the public, to act as a clearing house for complaints.

Further steps also were proposed for the joint collection of statistics and business figures and the conduct of economic research in the interest of business and the public at large.

Secretary Hoover in a brief address called upon the conference to establish an organization of business men to co-operate with the Department of Commerce in its campaign for the elimination of waste.

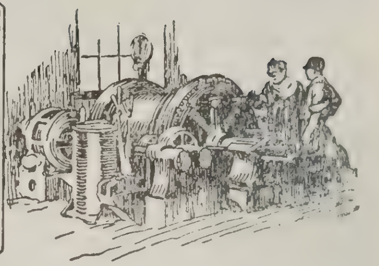
"We would be grateful," he said, "if there would come out of this conference some kind of an organization for the promotion and the better co-ordination of research; that some sort of definite, organized expression and impulse might be given to the building up of the statistical and research activities throughout the country. And I make that general expression because I believe that research, through the business world itself, and statistics so far as they may be competently collected, are in the hands of better agencies than the government."

Felix H. Levy, of New York, and other trade association representatives urged that the conference demand the amendment of the Sherman Act to enable business concerns to co-operate in the achievement of economic reforms and that the Senate Interstate Commerce Committee be requested to grant a hearing for the discussion of the question.

Other members of the conference asserted that the anti-trust laws were hampering business but that it would be inopportune at this time to urge their amendment or repeal.

"No little part of the wastes resulting in inflation of present prices the conference held to be attributable to unreasonable demands by consumers for unnecessary distribution services."

# Practical Pointers For Electrical And Mechanical Men



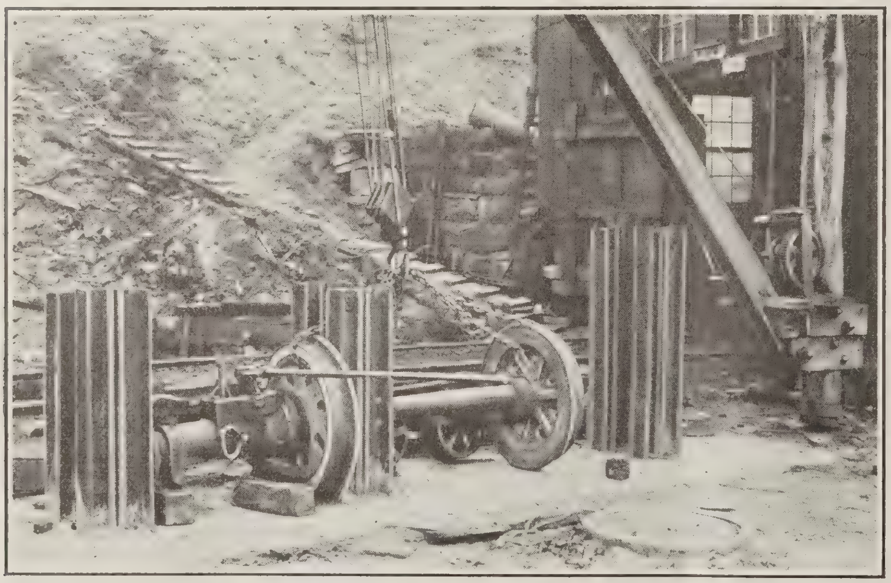
## Substitute Wheel Press Serves Purpose And Saves Expensive Investment

If a mine repair shop were equipped with every type of machine which occasion demands it would appear that the company was in the repair business instead of engaged in coal mining. The point to which it is economical to equip a repair shop depends upon the volume of work to be done and upon the proximity of a fully-equipped general shop rather than upon a sole consideration of the varieties and volume of the work it is called upon to perform.

A wheel press is one machine which if installed in many shops would be used only at infrequent intervals. This being the case at the shop of the Blue Diamond Coal Co., of Blue Diamond, Ky., Harry Kivett, chief electrician, was reluctant in advocating that the company invest in an expensive wheel press. Nevertheless, instances arose when a press would be of great advantage, so as a compromise he built the device illustrated in the accompanying photograph which admirably serves the purpose for which it was intended and does the work it is called upon to perform, although more slowly than would a regular press built specially for this work.

This consists of a number of pieces of 80-lb. rail set in a large block of concrete. A 75-ton geared jack of the portable type does the pressing and the rails act as backstops. A jib crane conveniently located facilitates the handling of heavy material to and from this improvised press.

The twelve pieces of rail are set in groups of four, with a 6-in. space between pairs. This space provides for free movement of the shaft or axle being pressed. The block of concrete is 5 ft. thick and the rails extend 3 ft. above the top. So far all pressing jobs which have come up at the Blue Diamond shop have been handled successfully by means of the 75-ton jack and this backstop arrangement.



**Using a 75-Ton Jack for Pressing Off a Wheel**

Each of the backstops consists of four 80-lb. rails set 5-ft. deep in a block of concrete. A crane facilitates the placing of material in the proper position for pressing. The arrangement, while admittedly not as good as a wheel press, does well for a shop where the volume of work hardly justifies the purchase of a standard machine.

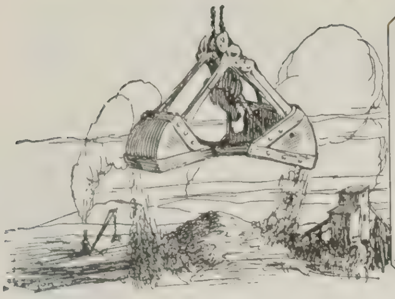
## Cone-Shaped Mandrel Assists Mine Blacksmith

"Shrink a band around it," is often the prescription handed to the mine blacksmith when some mechanical part is brought to him for repair. The shaping of the necessary band to a true circle is not an easy matter unless an old shaft, a piece of pipe or the like of right size can be found for use as a mandrel.

**Handy for the Blacksmith**

This cast-iron mandrel, 50 in. high, 5½ in. in diameter at the top, and 25 in. across at the bottom, is used for shaping rings, bands, and other curved forgings. Its size permits a great variety of work to be formed by its aid.

An old device, but one which nowadays is found in comparatively few mine blacksmith shops, is that recently added to the shop equipment of the Fordson Coal Co., at Stone, Ky. This is the cone-shaped mandrel shown in the accompanying illustration. It is made of cast iron 50 in. high, 5½ in. in diameter at the top, and 25 in. in diameter at the bottom. The top is solid but the bottom is cored out cone-shaped in order to reduce the weight. The range of sizes of bands or rings accommodated by this mandrel includes all of those for which there is a common call in mine repair work.



# Production And the Market

## Seasonal Lull Marks Bituminous Coal Market; Coke Takes Turn for Better

Year-end readjustment in the bituminous coal market is responsible to a great extent for conditions that have caused the trade to be in a frame of mind that is not exactly exultant. That is an old story, of course, in a business that has its full share of hard-boiled factors. This is not to say that it lacks optimists, for as a matter of fact it is the latter class who allow their cheerful expectations to blind their judgment, and when their hopes and predictions fail of realization—as many have since the hard-coal controversy first appeared on the horizon—due in large measure to overplaying hunches and the reappearance of the evils that no business can escape, they are grieved to hear aspersions cast at the industry.

It is gratifying to note that during the present difficulty the coal business has been freer than usual from practices of a questionable character. Like the cut-up who rocks the boat, the producer who is willing to "take a chance" and ship on consignment always is with us, and he eventually meets the usual fate, but there always is another to take his place. The better element in the trade—those with its best interests at heart—are sticking to ethical methods, realizing that such fundamentals as the survival of the fittest are still doing business at the old stand.

### Business Up to Seasonal Average

All things considered, the trade may be said to be pursuing a normal course. If business is not up to expectations—and it never is, in the estimation of some—that perhaps is because too much was expected. There is good reason to believe, however, that the outlook is better, for with the completion of inventories and the passing of the engrossing interests of holiday time there is bound to be a let-up in the marking-time policy now more or less prevalent, consumption continues apace and the end of the anthracite strike is not yet in sight. Curtailment of production by observance of the holidays at the mines also will tend toward a healthier condition in the market.

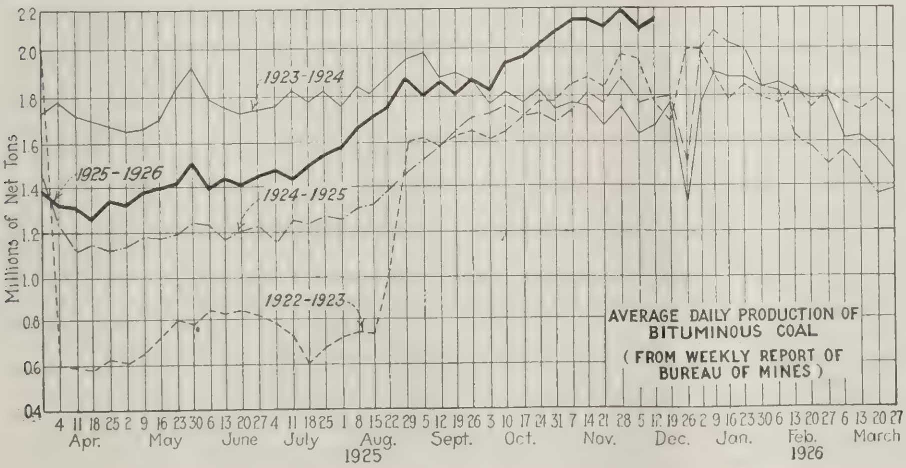
Governor Pinchot's efforts at peace in the hard-coal field having led nowhere in particular—save, possibly, deeper into hot water—resumption of mining seems to be as far off as ever. The special session of the Legislature called for Jan. 13 is likely to be productive of prolonged and acrimonious debate before accomplishing much in the way of results. Perhaps for that reason the demand for anthracite substitutes has improved, especially for coke, the price of which has taken a turn for the better.

### Production Nears 13,000,000 Tons

Bituminous coal production during the week ended Dec. 12 is estimated by the Bureau of Mines at 12,898,000 net tons, an increase of 31,000 tons over the revised figures for the preceding week and a mark exceeded only four times, but not within the last five years. Anthracite output in the week ended Dec. 12 totaled 64,000 net tons, compared with 62,000 tons in the previous week. Total hard-coal output during the calendar year to Dec. 12 is 62,009,000 tons, or 27.8 per cent less than during the corresponding period of 1924.

*Coal Age* Index of spot prices of bituminous coal stood on Dec. 21 at 179, the corresponding price being $2.17, compared with 182 and $2.20 on Dec. 14.

Dumpings of coal at Hampton Roads during the week ended Dec. 17 totaled 457,157 net tons, as against 337,558 tons in the preceding week.



### Estimates of Production

(Net Tons)

| | 1924 | 1925 |
|---|---|---|
| **BITUMINOUS** | | |
| Nov. 28 | 9,885,000 | 11,599,000 |
| Dec. 5 (*a*) | 10,831,000 | 12,867,000 |
| Dec. 12 (*b*) | 10,873,000 | 12,898,000 |
| Daily average | 1,812,000 | 2,150,000 |

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

## Midwest Trade Slumps Further

Lacking the aid of cold weather the Midwest market is in a disorganized condition, with coals offered at almost any price. Illinois and Indiana operators, when compared with producers in southeastern Kentucky, western Kentucky and West Virginia, however, have maintained their quotations unusually well. The main cause for the demoralization as usual, is too much coal produced and not enough demand.

Retail dealers will soon be in the market again, but it is obvious that as a rule they are not in the market now, being desirous of reducing stocks for inventory. They are quite willing to take a chance on coal being just as cheap around the first of the year as it is now, irrespective of labor and weather conditions.

Producers of high grade southern Illinois coal from Franklin, Saline and Williamson counties are sticking to their circular prices, although a few weak sisters have had to make sharp reductions to the big wholesalers in order to clear their tracks sufficiently to enable them to keep up production for steam contracts. Coal from non-union fields in the East and in western Kentucky continues to fleed the market, a good many hundred cars coming into Chicago on consignment now. Pocahontas lump coal of fairly good quality has been sold in distress in Chicago as low as $2.75. Pocahontas and other coal of recognized quality can be bought at $3.

The available market supply of steam coals continues to dwindle day by day, but apparently enough of it is coming in to take care of industrial demands, as purchasing agents show no interest in acquiring additional supplies.

The weather is not exactly seasonable and coal is not moving as it should in southern Illinois. Lump is moving rapidly, but there is a slowing up in egg and the other sizes. Domestic dealers report their yards pretty well loaded up and such coal as is moving is under pressure. Shaft mines are easing up in steam this week whereas last week there was brisk buying. A falling off in railroad tonnage also is reported. The strip mines continue to make good working time and apparently find a ready market. There have been no changes in prices and working time ranges from three to five days a week. There is no car shortage and the railroads show faster movement.

In the Duquoin and Jackson County field there is little change. The mines are getting four and five days a week and are having trouble moving all sizes. In the Mt. Olive field conditions are slow; railroad tonnage has eased off and domestic is fairly good, while steam seems to be holding its own. In the Standard field there has been an easing up and coal is selling at just about cost, with "no bills" at all mines and hard work to move all sizes. Railroad tonnage is slow. The mines are getting from two to four days a week. Prices are unchanged.

At St. Louis the weather is not the kind that calls for

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Dec. 21 | Dec. 14 | Dec. 7 | Dec. 22 |
| Index ................... | 179 | 182 | 184 | 170 |
| Weighted average price.. | $2.17 | $2.20 | $2.22 | $2.06 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1924, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

any unexpected movement of coal and some retailers are just fairly busy moving small orders—of middle grades chiefly, although there has been a fairly good demand in the past week for high grade from both southern Illinois and western Kentucky. There has been a light call for smokeless, but anthracite is slow and coke is about holding its own. Country domestic has been quiet, dealers reporting large supplies on hand. Local wagonload steam shows improvement, carload is just about normal and country steam is slow. No change in prices.

### Heavy Output Causes Weakness in Kentucky

Demand for coal in Kentucky continues fair, but production is so heavy and offerings so large that prices have weakened somewhat. The eastern Kentucky market is generally lower due in part to West Virginia mines quoting lower prices and moving large tonnage. In western Kentucky everything is weaker except screenings, which are being well maintained, at firmer prices, the market being kept cleaned up on pea and slack. Mine-run shows very little change in either field, prices being fairly firm, but a few lots are being offered at under the market.

General industrial demand is very good and the railroads are using a lot of engine, shop and general coal. Consumption is abnormally high for the season on steam coal, but mild weather and fair stocks in retailers' hands are making for just a little dullness in prepared, which probably would not appear dull except for the very heavy offerings.

Mines in eastern Kentucky which haven't operated in a long time have been running on the fall market, and car supply continues very good as a whole. Current loadings are very good. Western Kentucky is getting all the cars she needs to load, but needs orders worse than coal.

Prices for eastern Kentucky block are $2.75@$3.25, with some specialty coals priced higher; lump, $2.50@$3; egg, $2.25@$2.50; nut, $2@$2.25; mine-run, $1.50@$1.75; screenings, $1@$1.25. West Kentucky block is $1.85@$2.15; lump, $1.75@$1.90; egg, $1.60@$1.85; nut, $1.35@$1.50; mine-run, $1.25@$1.50; screenings, 80c.@$1.10.

### Northwest Trade Fairly Active

Coal-dock operators at Duluth and Superior have found business good during the last ten days, though no special rush was noted in any direction. Industrial demand has not been so active lately, but iron mining companies on the Minnesota ranges are coming into the market for fair tonnages, mainly of Youghiogheny dock-run and screenings. Retailers also have been filling out stocks that had become run down and utilities and the railroads have been taking fair tonnages.

The number of cars loaded at the docks during December is expected to compare favorably with November, and, thanks to good service by the railroads, the trade has been handled without difficulty.

Fifteen cargoes of bituminous coal were unloaded at the docks during the last week of lake navigation, which wound up Dec. 15. Stocks of bituminous coal on commercial docks at Duluth and Superior totaled 5,136,000 tons on Dec. 1; anthracite, 156,000 tons. Demand for Pocahontas and other smokeless coals as substitutes for anthracite continues to be the market feature. Briquets also are beginning to sell more freely as hard-coal stocks approach the exhaustion stage, which will be about the middle of next month.

Apart from an easier situation in prepared sizes of Pocahontas, which are now offered at $8.50, or 50c. off, the market is practically unchanged in either anthracite or bituminous coals.

Fuel conditions in Milwaukee have not changed in the last week. Demand fluctuates with temperature, but on the whole business is seasonable and satisfactory. In the absence of anthracite, consumers are using gas coke, process coke and low-volatile bituminous coals. Prices are steady.

### Cold Snap Livens Southwest

Colder weather has brought a resumption of activity in the Southwestern field. Mines in Kansas continued to work through the long period of mild weather, but a slight surplus of lump had begun to accumulate when freezing temperature livened the market and operators foresaw an early return to conditions of three weeks ago, when they were two weeks behind with deliveries. The change in temperature, however, had little effect on conditions in Arkansas, where mines have been working only part time for several weeks. Buyers of Arkansas semi-anthracite stocked their bins early in the fall, and these will not begin to run low until after the first of the year.

In Colorado the prevailing warm weather has had the effect of curtailing orders and depressing output. The mines are operating approximately 86 per cent running time. While there has been no cancellation of orders, the trade is withholding future orders anticipating a change in the weather. All the mines have caught up with orders that came with the heavy demand in October and early November. There seems to be an oversupply of labor now due to the sugar beet campaign having ended. Transportation conditions are excellent. Prices show no appreciable change.

The Utah trade still hopes for seasonable weather to stimulate the movement of coal for heating purposes. Demand for steam coal is at least normal for the time of year. Railroads have been consuming more than usual on account of heavy crops, and other industries using steam coal are enjoying prosperity. The coal business is going to be better in the country districts this winter on account of the prosperity of the farmers. No grade of coal is regarded as a drug on the market now. Two months ago there was a surplus of slack, but now the supply is scarcely sufficient to meet the demand. Domestic lump and straight lump are still leading grades in the consumers' market, but more slack and pea coal is being used for heating purposes than heretofore, as a result of the installation of smoke consumers. Oil burners are getting a foothold, but their progress is by no means sensational. The news that oil has been struck in Utah is expected to hurt the coal business more or less. Prices are steady and the labor situation good.

### Squeeze Continues at Cincinnati

Toploftiness in price, which has been a feature of the smokeless market at Cincinnati for three months or so, was pretty well dispelled during the past week. Distress lump has been hammered so hard by buyers and those who thought it to their advantage to "get out from in under" that sales are reported of odd lots at around $3 and even a shade less. Egg appears to have been a little better off, the lowest it went being $3.75. Contract holders say that they are still shipping the two at $5@$5.25, but there have been compromises in order to keep things rolling. The disposition is to hold mine-run as firm as possible. Screenings are weaker though the range has not been changed.

High volatile seems to have fared a little better. The raid on this price line-up has abated a little, even though the demand is not brisk. Hazard prices, taken as a criterion for southeastern Kentucky, hold at $3 for block; only over-anxious sellers go below that. West Virginia shippers, with an immense tonnage to keep moving, whittle here and there with the prices down to $2.50. Quality lump, however, has little bother in commanding $2.75@$3. Egg prices maintain their level of $2@$2.50 because of demand from Michigan points and Canada in the main. There is no change in the even tone which has marked mine-run for months. Screenings also have recovered their poise, this due more to seasonal uncertainty at the holiday period.

Only a spell of colder weather, it is believed, is needed to wipe out accumulations and the buying orders of the first of the month will tone up the market so that it should go forth with a bang.

Retail business is unchanged. River business is good, with the stage right and ports from Portsmouth to Louisville in grand shape to handle offerings over their elevators.

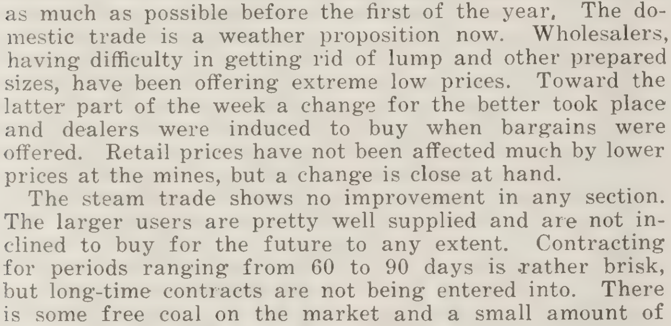
### Columbus Dealers Go Bargain Hunting

Weakness in domestic sizes has marked the Columbus coal trade during the past week. Warm weather and the approach of the holiday season have been contributing causes. Dealers have heavy stocks and desire to clean up as much as possible before the first of the year. The domestic trade is a weather proposition now. Wholesalers, having difficulty in getting rid of lump and other prepared sizes, have been offering extreme low prices. Toward the latter part of the week a change for the better took place and dealers were induced to buy when bargains were offered. Retail prices have not been affected much by lower prices at the mines, but a change is close at hand.

The steam trade shows no improvement in any section. The larger users are pretty well supplied and are not inclined to buy for the future to any extent. Contracting for periods ranging from 60 to 90 days is rather brisk, but long-time contracts are not being entered into. There is some free coal on the market and a small amount of distress coal, which sells at low figures.

Under the influence of reduced demand, output in southern Ohio has declined to between 25 and 30 per cent of capacity. Pomeroy Bend, which is operating on the 1917 scale basis, has been pretty busy.

In eastern Ohio demand is unusually dull and retailers are loaded up. Spot prices are unchanged since last week. Production is declining, eastern Ohio output in the week ended Dec. 12 totaling 309,000 tons, or 44 per cent of capacity. This was a decrease from the preceding week of 30,000 tons but an increase over the corresponding week of last year of 36,000 tons. Some distress coal is in evidence and the price tendency is soft.



### Industries Heavy Consumers at Pittsburgh

Demand in the open market for coal at Pittsburgh seems to be a trifle better this week, though the falling off in buying weeks ago is exerting a downward influence and the appearance of the market is weaker. Youghiogheny gas coal, which for several weeks it was quoted at $2.75@$3, has shown a trading range in the last few days of $2.60@$2.75; Westmoreland County gas is $2.50, being sometimes shaded. Gas mine-run is quotable at $2@$2.25, depending on the urgency of the seller. Steam coal runs the same as formerly, $1.40@$1.50 for slack, $2@$2.10 for mine-run, and $2.25@$2.50 for ¾-in. Industrial consumption of coal is quite heavy, as the industries are running very well.

The straight bituminous trade in Buffalo is quite as slow as ever, with prices very unsteady. Slack is scarce and gas coal is not plentiful, but the consumer is indifferent, having, it is said, more coal in stock than almost ever before. The smokeless trade has not done much yet, the price having advanced only from $6 to $6.75, while coke has gone up $3 and probably will soon go still higher. Quotations: $1.60@$1.75 for Fairmont lump, $1.40@$1.50 for mine-run, $1.25@$1.40 for slack; $2.25@$2.50 for Youghiogheny gas lump, $2@$2.25 for Pittsburgh and No. 8 steam lump, $1.30@$1.60 for slack; $1.75@$2 for Allegheny Valley mine-run.

### New England Trade Unseasonably Dull

The market for steam coal in New England, considering the season, is extremely dull. Apparently the domestic consumer who was relied upon to absorb a heavy tonnage has not risen to trade expectations. The fact is that bituminous output had already been built up to large proportions when the slump came, and there was a limit to what retail dealers would take on in advance of actual demand from the public. There are many now who say it was a mistake to encourage the use of prepared bituminous in this market. This is a territory that has been served by rail and water—a route economically cheaper—with low volatile run-of-mine, and the publicists who recommended lump, egg and nut from the smokeless districts failed to take into account both the expensive routing all-rail and the buoyancy of price that immediately results from insistent demand on the producer. Except in sparing quantities the industries, too, are not buying; most of the mills and utilities accumulated reserve stocks months and weeks ago, and are not likely to be interested in anything but deliveries on contract for a while.

At Hampton Roads the spot market is almost soft, and new low levels in price are anticipated. Owing to the pressure of increasing volume on the rails No. 1 navy standard Pocahontas and New River coals are being offered at less than $5 per gross ton f.o.b. vessel, with intimations that lower figures would be acceptable for prompt loading. A few cargoes of splint coal are coming forward as a substitute for anthracite at an average price of $3.50 per net ton at the mines. There would probably be a better opening by water than by rail for coal of this character, although much would depend upon how well it stands rehandling.

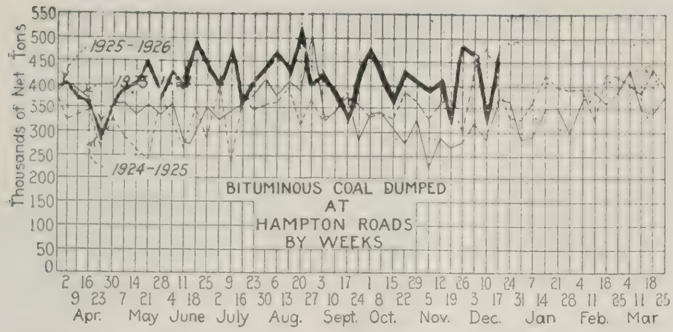
Cargoes of foreign coal continue to arrive in reasonably large volume. Less fancy Welsh anthracite is included than was the case a month ago; the desirable kinds and sizes were bid up to prices beyond the reach of ordinary retail distributors. The importation of Scotch and German coke, especially metallurgical coke, doubtless will be abandoned. Results have been unsatisfactory and there are dealers who have it on their hands and are unable to find sale for it. Patent fuel, such as ovoids, however, seem to be going fairly well and are offered at retail at around $16 per net ton. Boston retail dealers still have Pennsylvania anthracite they sell for $18 per net ton delivered.

On cars Boston and Providence the prices of smokeless coals range $6.10@$6.50 per gross on for inland delivery. Inquiry is very light.

### Buying Is Fair in New York

Industrial consumers of bituminous coal in New York are taking in fair-sized tonnages of mine-run grades, both by rail and over the tidewater piers. Considerable tonnages are used in office buildings and other structures as a substitute for the smaller hard coals. Screened coals are in fair demand but are not up to expectations.

Quotations for low-volatile lump from central Pennsylvania range $3.50@$4.50; Broad Top coals, $5.75@$6.25. New River and Pocahontas prepared grades are priced



around $4.50@$5 at the mines. There is a fair demand for these coals in this market.

The Philadelphia market remains somewhat quiet, although there is some expectation of better business because of colder weather and failure to clear up the anthracite situation. Regular users of bituminous coal continue to take fuel in good volume, but even the threat of winter storms has brought no disposition to add to commitments.

Producers of screened coals, particularly low volatile, report better inquiries and shipments. Concerns producing high-volatile grades are getting more orders, but are far from having anything like the business they had hoped for.

Everything remains quiet at tidewater in the way of export orders, and few inquiries have been received of late. Bunkering is easily cared for. Prices remain fairly stable.

Little change is to be noted in the bituminous situation at Baltimore. Industrial call has been moderate, the amount of fuel on hand is liberal, to say the least, and competition in selling is so keen that at times it approaches the point of trading without profits. Even in prepared sizes, used as substitutes for anthracite, there is not the activity expected; these are quoted at $2.15@$2.25 f.o.b. mine. One of the things that troubles coal men now is the falling off in the export and bunker trade.

Steam coal is very active in Birmingham and there is no surplus of any grade. Coking coals and washed product suitable for the bunker trade are exceedingly scarce and the demand strong. Current consumption in the industrial field and among the utilities and railroads is heavier than at any other time during the past year, several of the rail lines having been in the open market trying to buy fuel to supplement their contract deliveries, on which they are taking the maximum tonnage. A certain amount of this coal is being stocked for the holidays, but the movement is much heavier than at this season for several years past. Bunker fuel is being bought in larger quantities than usual and some trouble is experienced in keeping the required tonnage moving to the ports. Some mines in the district had to decline some of this business altogether during the past week. Quotations on washed Cahaba and Black Creek now range $2.75@$3, mines. There has been no change in the range of other steam quotations during the past week.

Inquiry for domestic sizes is not as strong or insistent as it had been, but there is ample business in hand at the mines to take care of production for several weeks yet, and a fairly good number of orders are being taken on to supplement such bookings. The weather has been unseasonably warm for several weeks, which has militated against the active buying of household fuel. Quotations on domestic coals are unchanged.

An output of 435,000 net tons was reported for the week of Dec. 5, which is the highest for a similar period since 1918. Car supply has been sufficient to keep the mines going without delay for the past several weeks, but should production be increased very much a shortage no doubt would materialize.

## Demand for Hard-Coal Substitutes Spurts

Improvement in demand for the various anthracite substitutes in New York last week resulted from lower temperature. Buying by retailers and consumers was on a larger scale. Coke appeared to take the lead, although there was a heavy demand on retailers having some anthracite. Anthracite domestic coals are quoted as high as $23.50 by dealers able to make deliveries.

Consumers are not as optimistic of the ending of the strike as they were last week and are more willing to lay in more fuel.

There is some No. 1 buckwheat still afloat in the New York harbor. Good grades are quoted at $8.75 to $9.25, while mixed buckwheat, containing, it is claimed, about 50 per cent undersized coal, is quoted at $8 to $8.25, alongside. One day last week it was said there was one cargo of pea coal available in the harbor, which was held at about $17 alongside.

Coke has taken an upward turn. Quotations are up about 50c. Egg size is quoted at $5.50@$6; nut and stove sizes at $6@$6.50. Coke in boats in the harbor is quoted at about $10 alongside.

At Philadelphia an increased demand for fuel of all kinds has sprung up since Governor Pinchot's first peace efforts went up in smoke. Shippers of byproduct coke are again sold up weeks in advance, with beehive coke following closely on its heels. Prices have advanced, most of the sized beehive selling at $6@$7 at the ovens while byproduct brings about $10@$11 delivered.

Most all anthracite coal is now out of the retail yards, although a few dealers have small quantities of pea and buckwheat. The one company that had been shipping some pea and buckwheat here for the last several weeks now announces that its storage yards are empty.

At Baltimore the hard-coal situation is confined to some isolated instances of selling out of the usual run, as the larger dealers no longer have anthracite to offer of any size. A number of small fly-by-night traders have arisen, and are disposing of peck and bushel lots of soft coal, or hard coal where they could get a little at any reasonable price. These small dealers in many cases were not content with the profits they made from stiff prices for pecks and bushels, but used short-weight measures.

Buffalo's anthracite supply is coming to an end, having lasted much longer than expected. Coke is active and is getting scarce. Byproduct coke makers are withdrawing price quotations or putting them up. There is a good demand for buckwheat anthracite, but the schedule companies are all about out of it; there is still a fair supply of it in the hands of independent dealers, however.

## Connellsville Coke Market Stiffens

The Connellsville coke market, after softening on first-quarter contract coke for blast furnaces, letting most of the uncovered furnaces in, has stiffened sharply in the last few days in prepared coke, resulting in higher prices for run-of-oven furnace coke.

In blast-furnace contracting, when offers at $4.50 and then at $4.25 did not interest furnaces, some operators became perturbed, and, anxious to book backlogs, closed a number of contracts at $3.75@$4—about an even dollar above the average of the contracts about to expire, made last summer. It appeared then that operators who had not sold any backlogs would also name these prices, but with the stiffening in the spot market this may not prove to be the case.

The turn in spot and prompt coke was due to various dealers, both in Pittsburgh and in the East, discovering that other dealers also were short, rushing to cover. Yard crushed coke had sold in a few cases at down to $4.25, but it is up to $6 now. It turns out also that operators sold pretty heavily recently at low prices and some are if anything oversold. Further advances are a decided possibility.

While the rush to buy is chiefly in broken, yard crushed, egg, regular crushed, etc., there is a strong influence on run-of-oven coke, which may now be quoted at $4, against $3.50@$3.75 a week ago. Some furnaces already have paid up to $4, it is said. Some have been buying extra lots, as is often done just before the holidays, to tide over a possible dip in contract shipments.

Spot foundry coke remains quotable at $4.75@$5.25, but is likely to advance. Contracts over the half year are quotable at the same range.

## Car Loadings, Surplusages and Shortages

# Foreign Market And Export News

## British Market Reflects Steady All-Round Gain; Output Still Climbing

A steady business continues in the British market for steam coals. Collieries are engaged busily on inland orders, which have perceptibly improved. Export inquiries flow at a fair pace, though much French business is reported in abeyance pending improvement in the position of the franc. The improving tendency in Italian demand remains in evidence, and a fair average business passes with the depots in South America, Spain and Portugal. Intimation has been received locally of possible heavy demands on Wales. A little more interest has been, and is, manifest in contract business, though buyers and sellers are at variance over prices and selling is mainly up to next April. Small coals are a strong section, this being due to larger bunker business, which includes increased proportions of smalls. Best Admiralty large is moving well for early loading. Monmouthshires are meeting with a better demand after prolonged inactivity, though supplies are momentarily adequate, apart from smalls. Patent fuel also is enjoying better business at easier prices.

Bad weather in Newcastle has delayed tonnage supplies again, and the prompt business in the coal market is very erratic in consequence, buyers with guaranteed tonnage being well placed for obtaining discounts. The forward outlook, however, is fairly straight, and the sellers of both coal and coke are making no concessions on recent quotations. Just how far the coal subvention is assisting matters it is difficult to determine, but it is thought that the present selling prices will enable producers to keep on selling coals, but the prices themselves are not possible without the subsidy. Therefore, the anxious time is between now and the end of the subsidy period. The coke market continues to improve. There is a fairly healthy export demand for this class of fuel.

Production by British coal mines during the week ended Dec. 5, according to a special cable to *Coal Age*, totaled 5,210,000 gross tons, compared with an output of 5,185,000 tons in the preceding week.

## Trade in French Market Takes Favorable Turn

The situation in the French coal market is generally favorable. Available supplies have increased somewhat during the last few days and this has made it possible to meet a slightly larger demand from the industry.

The depreciation of the French franc affects especially industrial grades, as there cannot be any question of curtailing imports of domestic coals. Wintry weather has increased the demand for house fuels, but Paris dealers note that consumers are ordering only small quantities at a time.

Imports of British coals are again decreasing, but still the news that the prices of Welsh anthracites have ceased rising was greeted with pleasure.

Notwithstanding their strong representations, Paris coal merchants have had to agree to pay for Belgian coal on the basis of the Belgian franc.

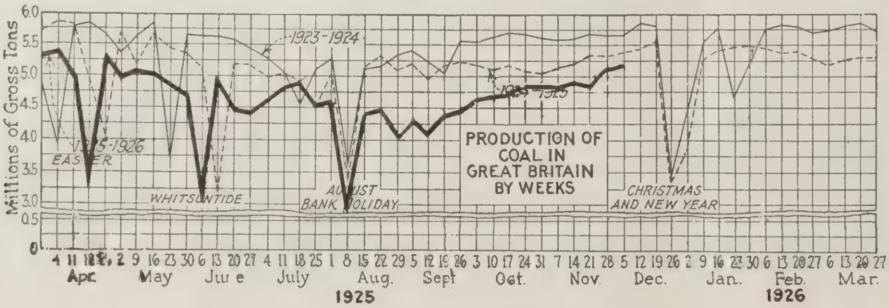
Indemnity fuel deliveries from the Ruhr during the first twenty-one days of November included 330,700 tons of coal, 149,300 tons of coke and 20,400 tons of lignite briquets. During the entire month of November, the O. R. C. A. received from the Ruhr 208,210 tons of coke, a daily average of 6,940 tons.

The prices of reparation fuels delivered via Rotterdam, Antwerp or Ghent, which were raised on Nov. 16, were again advanced from 3 to 7 fr. on Dec. 1 owing to the depreciation of the franc.

## Business Dull, Prices Weak At Hampton Roads

Business at Hampton Roads last week was very dull, with prices weakening perceptibly, in the face of slackening demand. Prices at the mines were reported as having dropped materially, Pocahontas nut and egg having dropped from $8 per net ton mines to $4.50.

New England business was slower than normal for the season and foreign business was scarcely holding its own. The bunker trade was showing only fair activity.



## Weak Tone in Belgian Market

The tendency in the Belgian coal market remains weak except for house coals. On the whole demand is still meager and, notwithstanding the restriction of output, pithead stocks are not decreasing. Competition of French coals is very active, as is also that of Dutch and British coals.

The situation is particularly bad in the Borinage district. In the other fields indications point to a slight improvement.

Operators declared that the present circumstances make it impossible to maintain the 5 per cent increase in wages agreed to for November. Conditions in the trade remain unfavorable and the measures taken by the government for remedying them have so far been of no avail.

# News Items From Field and Trade

## ALABAMA

George Gordon Crawford, president of the Tennessee Coal, Iron & Railroad Co., has announced that $10,000,000 will be spent for additions and new construction at the Fairfield division of the corporation. A battery of seventy-seven 16-ton byproduct ovens will be added to the present plant composed of 434 ovens and a belt conveyor will be installed to carry coke from the ovens to the furnaces.

## COLORADO

A new coal company has been organized under the name of Barbour Coal Co., which will start to develop a coal mine in Huerfano County on the Rio Grande R.R., between the Alamo mine and Kebler No. 2 mine. The principal owners of the new company now control the Alamo Coal Co. and the Oakdale Coal Co. About a million dollars, it is said, will be spent in developing the mine.

The citizens of Frederick have sued the Evans Fuel Co. et al for $22,000 damages, alleging that improper coal mining methods are causing the plaster to fall and walls to crack in their homes, while holes are forming in the main street.

## ILLINOIS

Sale of 12,500 shares of the 15,000 shares of the stock of the defunct Southern Gem Coal Corp. was approved by Judge English in the U. S. District Court in East St. Louis, Dec. 11. The sale was to have taken place Dec. 8, but objections of a technical nature were filed by certain of the original stockholders. According to the terms of the sale the receivers of the defunct company received $100,000 in cash for the property, and the purchaser, the Brewerton Coal Co. of Lincoln, assumes mortgages and obligations totaling $1,633,000. It is expected that a portion of the mines will be opened this winter.

The Illinois State Miners' Examining Board has announced its January schedule as follows: Belleville, 11th; Harrisburg, 12th; Herrin, 13th; Marion, 14th; Benton, 15th; Duquoin, 16th; Litchfield, 18th; Springfield, 19th; Pana, 20th; Danville, 21st; Farmington, 22d.

Dr. Edmund H. Stinnes, owner and operator of large coal properties in Germany, was a visitor to the southern Illinois coal field last week. Dr. Stinnes spent some time in several of the larger mining centers in southern Illinois, with West Frankfort as his headquarters. He was shown the bottom and top works of several mines, including No. 9 of the Old Ben Coal Corporation. In his tour of the United States Dr. Stinnes' general purpose is to study economic conditions in industrial centers. While in the local mining fields he declared that conditions were much more favorable in this country for coal mining than in his own country.

According to information available now, the prospects of the proposed merger of mines in the Standard and Mt. Olive fields seems to be at an end. Recent conferences, according to reports, show that the financial features of the proposition are almost too big for the people that are now handling it.

## IOWA

The Dallas coal mine, one of the largest in Polk County, located northwest of Granger, has been purchased by the newly organized Dallas Products Co., of which Russell E. Carlson, H. M. Havner and Hugh Shuler are the principal stockholders. The company is capitalized at $250,000. Arrangements have been made to operate the mine at once. The output of the Dallas mine runs between 400 and 500 tons daily. The Dallas Coal Co., former owner, has been in receivership since April 10.

## KANSAS

An attempt to blow up and burn the fan house and tipple of the Moore Coal Co. mine in the southeastern Kansas field, early in the morning of Dec. 11, was frustrated when a man living near the mine discovered smoke issuing from the tipple and summoned aid to extinguish the fire. A keg of power was exploded under the belt wheel of the air fan in the fanhouse setting fire to the building but no serious damage resulted. A pile of oily waste had been ignited in the tipple. The total damage was estimated at not more than $50. No clues were found. The mine employs forty union miners.

Coal operators of Kansas are on the warpath against so-called "compensation leaches," who they say enter fraudulent claims for compensation. Insurance adjusters are insisting, they say, that action be taken to reduce the number of alleged unjust compensation claims, under a veiled threat of withdrawal. Formation of a central body, or "compensation clearing house," has been suggested, and it is understood a strong lobby is to be formed by Kansas coal operators at the January, 1927, session of the state legislature to urge changes in the state compensation laws.

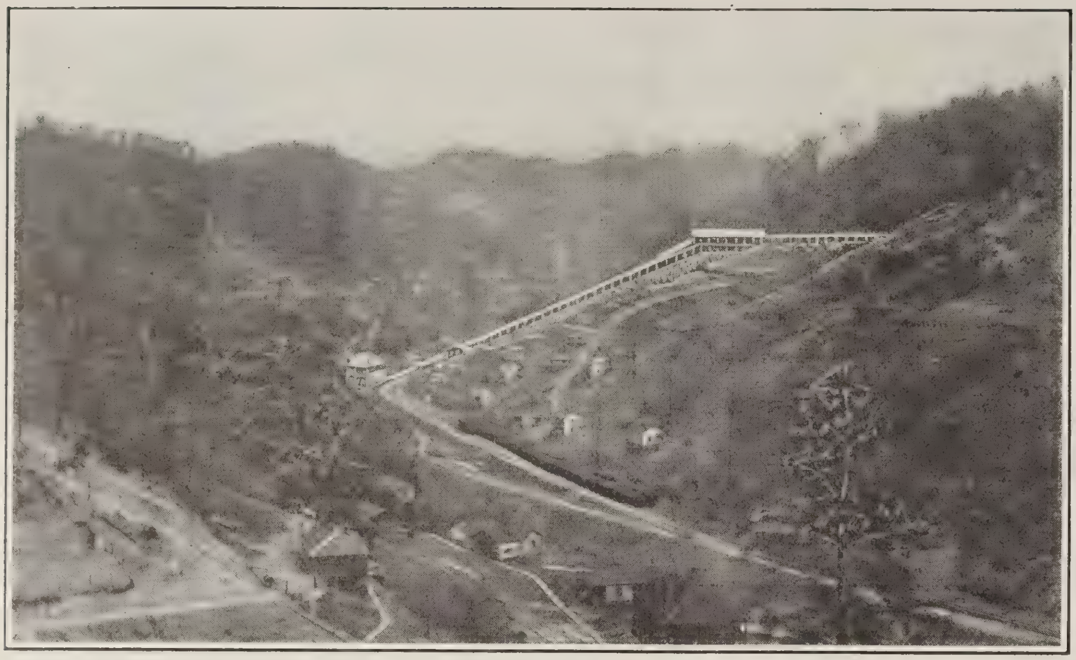
Jesse S. Rogers was appointed Dec. 1 to the position of state mine-rescue superintendent at the Arma state station, to succeed William ("Whitey") Hislop, who was transferred permanently to the central station at Pittsburg, succeeding William Morrison, who resigned Oct. 1. John L. Young, deputy state mine inspector, appointed Oct. 1, resigned effective Dec. 1 to take a position as inspector for the Associated Insurance Companies.

James Sherwood, state mine inspector, has ordered the discharge of two employees of the Wilbert-Schreeb Coal Co. who were caught tamping shots with coal drillings, which is against the law. An explosion in this mine caused a property loss of $1,000 and nearly cost the life of a shotfirer.

Prosperity of Kansas miners during the past few months is reflected in their vote to dispense with a 4-per cent special assessment levied early last summer for the benefit of striking and unemployed coal miners. The special levy was lifted Dec. 1. A proposal to vote a 2-per cent assessment for aid purposes was voted down by a big majority.

A referendum vote on whether district headquarters of the Kansas miners will be retained at Pittsburg or removed to Frontenac or Arma, in the same county, will be taken by the miners on Dec. 29, and returns will be in the hands of the secretary not later than Jan. 10. Headquarters offices are now maintained in rented quarters in a Pittsburg office building. Miners and business men of Arma have agreed to donate $10,000 toward erection of a building there to cost $28,000. Frontenac miners have agreed to give their local union building, known as Miners' Hall, to the district. A majority vote for either project will be necessary to carry.

Miners of Kansas will vote Dec. 22 in a run-off election to select one of two candidates for district auditor. Votes will be counted Dec. 29 and the newly elected auditor will take his position Jan. 1. At the primary election there was a field of thirteen candidates. Jack Toschi of Ringo polled high with 1,137 and Arthur Eagleton was second was 690. They will be on the ticket in the run-off election.



**Up First Creek Valley**

Looking up the valley of First Creek from Blue Diamond, Ky., one can see located on the hill at the right the mine of the Sapphire Coal Co. now under the management of the Blue Diamond organization.

## KENTUCKY

Flames which swept the Kentucky Coal Co. mine two miles west of Sturgis, Dec. 11, destroyed 30 wooden railroad cars of the gondola type, burned track and other inside equipment and finally forced sealing of the mine. Exact extent of the damage will not be known until the shaft can be unsealed. Several fire fighters were overcome while battling the flames more than 100 ft. below the surface, but no one was seriously hurt. A short-circuit in the automatic charging panel is believed to have started the blaze. The mine was the scene of a disaster last June, when 17 men were killed in a gas explosion.

The Cornett-Lewis Coal Co., of Louellen, Harlan County, has contracted with the Morrow Mfg. Co., of Wellston, Ohio, to construct a modern steel tipple with a capacity of 3,000 tons per day. The coal, which at this point is 85 ft. below the level of the railroad, will be dumped at the bottom and conveyed up a slope to the tipple by means of a rubber belt conveyor.

George O. Boomer, treasurer of the Pittsburgh Fuel Co., Louisville, is one of eighteen men named, from which nine directors will be elected by the Louisville Board of Trade in the annual election, to serve with nine holdover members.

The Consolidation Coal Co., at Jenkins, recently obtained J. H. Childress, deputy sheriff of Pike County, to be in charge of the private policing of the company at the Burdine plant.

A. T. Siler, wealthy coal operator and president of the Bank of Williamsburg, married Miss Minnie Murphy, of Williamsburg, a member of the State Republican Executive Committee, at Louisville, Dec. 12. A number of friends from Williamsburg, including D. B. Cornett and Joe B. Mahan, were present. Mr. Siler was State Railroad Commissioner from 1904 to 1912 and very active in state politics.

George T. Cross, City Buyer of Louisville has been reappointed to that office for a period of four years under the new mayor, A. A. Will. Mr. Cross was a manufacturer before becoming city buyer.

## MINNESOTA

The North Western Fuel Co.'s dock No. 1, at Superior, and the Inland Coal & Dock Co.'s dock at Duluth were credited with receiving the last cargoes of coal for the season, steamers locking at their plants on Dec. 16. With the completion of the addition now under construction at the inland dock it will have a length of 3,000 ft.

Coal receipts at the head of the lakes for the season just closed totaled 9,455,864 tons, as against 8,716,158 tons in the 1924 season. Stocks on hand Nov. 30 were 5,648,134 tons, of which only 171,120 tons was hard coal.

The former Superior dock at Duluth now operated by the Henry Ford interests received 499,999 tons of coal during the 1925 season of navigation, according to the report of James Patten, its superintendent. The coal was delivered by the two Ford steamers, Henry Ford II and Benson Ford, and it was supplied from the Ford Kentucky mines. Supplies of that coal are being carried on the dock and it will be distributed at Minneapolis and nearby territory during the winter. The East End Coal & Ice Co. is handling Ford coal on the Duluth market.

## MISSOURI

Plans are being made for coal development near Nevada, Mo. Two brothers are behind the proposal, one of them from Chicago, where he is a member of the faculty of Chicago University. About 1,000 acres of land has been leased between Greene Springs and Dederick and sufficient prospecting has been done to prove that it is underlaid with 31 in. of good coal with a good roof. The M. K. & T. Ry. has already agreed to put in a spur to the mine.

## NEW YORK

The Acme Gas Coal Co., of Buffalo, with mines at Greenburgh, Pa., of which J. J. Eagan, of Buffalo is vice-president, has changed its name to the Acme Coal Mines Co.

Of the 23 reducing furnaces in the six plants of the Buffalo district 13 are running. The Bethlehem Steel Co., which lately blew in a new one, is operating five of these.

## OHIO

The Hisylvania Coal Co., of Columbus, which for years has been operating Mine No. 23, at Glouster, stopped operations Dec. 11 and abandoned the property, as it has been worked out. The mine was one of the best known in the Hocking field and produced a large tonnage. The equipment, consisting of machines tipple and tracks, is being moved to the West Virginia property of the company, acquired a year ago at Swiss, in Nicholas County, on the K. & M. R.R.

The offices of the Lorain Coal & Dock Co. were moved, effective Dec. 14, from the Huntington Bank to the First National Bank Building, Columbus.

The Columbus Board of Purchase will receive bids Jan. 23 for 15,000 tons of nut, pea and slack for the municipal lighting plant; 8,500 tons for the Scioto River pumping station, and 3,000 tons for the garbage disposal plant. These purchases are designed to supply these departments until April 1, 1926.

A. & R. Brenholts, wholesaler, 165½ North High St., Columbus, has taken over the output of the May Coal Co., at Alphretta, Ky. The output, which is about 500 tons daily, being sold from the Columbus office.

On the evening of Dec. 16 the Cincinnati Coal Exchange held a dinner dance and Christmas party at the Hotel Alms with Judge Joe Tuohy, president of the Coal Service Co., in the role of Santa Claus. Later he broadcast over WKRC the simple story of coal for the benefit of the radio bugs. Julius Ratterman, Elmer Wierkake, John Glaser, Bob Dickson and Fred Legg were in charge of the affair. About 160 persons were present.

Fred Gorc, general manager in charge of sales of the Blue Diamond Coal Sales Co., of Cincinnati, is a patient in Dr. Mayo's hospital at Rochester, Minn. Lung trouble which forced him to take a rest for months was found to be caused by the lodgement of a small bone that a simple operation would remove. Another patient there is Burke Keeny, president of the Middle West Coal Co. and the Cincinnati Coal Exchange.

V. G. Miller, in charge of the Columbus branch office of the Dickinson Fuel Co., of Charleston, W. Va., reports that the seven mines of the company situated in the Cabin Creek and the Pond Creek fields are in operation. Much of the product is moving through the Columbus office.

Workers are cleaning up the mine of the Black Diamond Coal Co., located near Glouster, preparatory to resuming operations after an idleness of months. It is announced that about 200 men will be given employment.

Disregarding a custom which has been in vogue for many years, the Belmont County district of the United Mine Workers will not hold its annual convention at Bellaire in January. It is announced that there is no reason for the meeting as the Jacksonville scale does not expire until April 1, 1927.

According to James B. Dugan, secretary to the Ohio Utilities Commission, the coal production in Ohio for 1925 will fall considerably short of the output in the previous year. The total for the state up to Nov. 1 is roughly estimated at 19,180,850 tons, as compared with 21,178, 650 tons during the corresponding period in 1924. The southern Ohio field has yielded 4,220,000 tons as against 4,734,000 tons for the same period in 1924.

## OKLAHOMA

Through efforts of district officials of the miners in Kansas, Missouri, Oklahoma and Arkansas, comprising the Southwest district, International President John L. Lewis of the miners' union has authorized appointment of a commission representing the international organization to investigate charges of the miners that operators in non-combatant states are "aiding and assisting" Oklahoma operators in the conduct of a battle against the miners to reduce that state to the 1917 wage scale.

The Major Brothers, of McAlester, have leased a coal mine seven miles southwest of Haileyville and expect to begin operations at once.

Officials of district No. 21, United Mine Workers, deny that Dewar miners' local has disregarded union mandates by returning to work in the Cameo Coal Co.'s No. 6 mine. The records of the Kansas, Oklahoma & Gulf R.R., however, show that the mine has shipped 14 cars of coal since Dec. 7, when 35 union men were reported to have gone back to work under the 1917 scale rather than accept 70c. a week strike benefits while walking delegates received $14 a day. The mine had been closed several months.

## PENNSYLVANIA

The Pittsburgh Coal Co. on Dec. 12 distributed a payroll of $60,043.37 to miners employed in the operations in the Pittsburgh district. Midland mine led with $17,594.27; Banning No. 1 had $15,680.55; Banning No. 2, $15,571.38; Montour No. 10, at Library, $11,197.17. These are all on the 1917 scale and the number of men who participated were 231 at Midland, 145 at Montour, 247 at Banning No. 2 and 229 at Banning No. 1. The miners in the five operations of the company dug more coal during the week ended Dec. 12 than at any time since operations have been resumed. The total tonnage was 20,942. Banning No. 2 led with 7,192 tons, Midland produced 4,780 tons, Montour No. 10, 3,698 tons, Banning No. 1, 4,632 tons, and Mansfield, 640 tons.

The Davidson mine of the H. C. Frick Coke Co., which has been idle for more than a year, will resume about the first of the year. The Hostetter-Connellsville Coke Co., a subsidiary of the Frick company, also has started up more than 200 ovens at the Whitney plant. The coal from the Davidson mine will be shipped to byproduct plants and the string of ovens will remain cold. In one quarter it was declared that it was unlikely that these ovens would be operated again.

The Bethlehem Mines Corp., subsidiary of the Bethlehem Steel Corp., and which is the only coal company in the Pittsburgh district, working on the 1917 scale with the exception of the Pittsburgh Coal Co., plans to put a second mine in operation before the end of the year. This mine is the Acme property, near Bentleyville, not far from the other unit working, known as the Marianna mine. On Dec. 15 a mysterious fire destroyed an untenanted company house at the Acme mine, causing $2,500 damage. Union sympathizers are blamed.

Nearly 4,000,000 tons of coal was mined in the city of Scranton in the eight-month period from Jan. 1 to Sept. 1, according to the report of the City Mine Cave Engineers, Frank B. Davenport and Frank Gaffney, which was issued last week. The Glen Alden Coal Co. led in production with 933.58 foot acres, or a total—at 1,500 tons per foot acre—of 1,400,250 tons; the Scranton Coal Co. was second with 535 foot acres; the South Penn Collieries, third, with 337 foot acres, and the Pennsylvania Coal Co. next, with 296 foot acres. With the 2,464 foot acres mined

**Modern Tipple at Wolf Run, Ohio**

This up-to-date preparation and loading plant of the Warner Collieries Co.'s Wolf Run mine is located at Wolf Run, Jefferson County, Ohio. Modern equipment which includes shaker screens picking tables and shaker loading booms, prepares lump, egg and nut and also loads mine run and slack for shipment over the Alliance Division of the New York Central R.R. which serves the Wolf Run Mine.

this year, the coal land assessable in 1926 is 46,566.16 foot acres, which has a valuation on the $320 figure of $14,901,120. If the new $800 valuation should be upheld by the court the coal land subject to taxation would be assessed at $37,252,800.

The Snowdon Coke Co., of Brownsville, has placed an order with the Fairmont Mining Machinery Co. for a large steel tipple, a structural steel trestle as an approach to a steel bin to store slack coal, and shaker screens, loading booms and other equipment. The work will be completed during the latter part of March.

Congressman Charles Esterly, of Reading, has prepared a bill for presentation in the House asking for a federal appropriation to dredge the Schuylkill River, thereby making it possible to reclaim thousands of tons of anthracite from the bed of the stream. It is understood that already in the Reading section arrangements have been made to turn this culm from the river into briquets.

## UTAH

The Denver & Rio Grande Western R.R. has set aside $100,000 to be used for continuing work on the Salina Canyon road to the coal mines above the town of Salina. It is expecting the road will be in operation next year.

## VIRGINIA

The City of Norfolk is contemplating replacing much of its coal-burning equipment with oil burners because of difficulties with the grade of coal it has been buying. The City Manager has announced that he finds it extremely difficult to get the proper quality in coal, and already several pieces of coal-burning equipment have been slated for replacement with oil burners. Some of its steam apparatus will be removed and electrical equipment installed, the city to buy its power from private concerns.

## WEST VIRGINIA

Work of rock-dusting Mine No. 42 of the Bethlehem Mines Corp. at Dakota, Marion County, was started Dec. 15. The work of rock-dusting mine No. 41, at Barrackville, where an explosion occurred last spring, recently was completed. Three coats of rock-dust were applied to all parts of this mine, according to N. A. Emslie, the division superintendent.

Chester C. Shinn, who has been in the employ of the Consolidation Coal Co. for more than 25 years, was named manager of the Fairmont sales office, which was opened in the Watson Building in Fairmont Dec. 16. Mr. Shinn will have charge of coal shipments in northern West Virginia, eastern Ohio and western Maryland. The Fairmont office also will handle the local coal trade for Fairmont and vicinity from the New England mine of the company, at Watson.

A spark from a welding machine being used by miners at the tipple of the No. 114 mine of the Kanawha & Hocking Coal Coke Co., at Longacre, caused a $40,000 loss by fire on Dec. 14. There had been a breakdown in the dump and the men were welding an angle iron. The flames destroyed the head house, pit mouth and the conveyor system. In order to save the tipple it was necessary to dynamite the conveyor system about one-third of the distance from the head house. The fire did not interfere with production, as the coal was shipped out from the other side of the hill, from the opening known as the No. 111 Carbondale.

A hard surface road between Clarksburg and Bridgeport, in the coal fields of northern West Virginia, was opened to the public Dec. 20.

Seals at Federal mine No. 3 of the New England Fuel & Transportation Co., where a mine fire occurred Feb. 3, 1924, were removed Dec. 15. Approximately 13 acres of Pittsburgh coal land were sealed. It is reported that the company will start producing coal soon in that portion of the mine.

Mines in the 12½ counties of northern West Virginia paid the miners for the last half of November in the week ended Dec. 12, when it is estimated that from $1,150,000 to $1,170,000 was paid out. Reports state that 1,301,800 net tons of coal were mined during that period.

Four buildings of the Crab Orchard Improvement Co., operating six mines at Eccles, near Beckley, were destroyed by fire on the morning of Dec. 12, at an estimated loss of $100,000. Operation of the mines was not stopped by the fire, although destruction of buildings and machinery has interferred with repairs. The machine shop, electric shop and blacksmith shop with their contents and the hoisting apparatus at the No. 3 opening and the building housing it were destroyed. The belief is expressed that the wiring in the machine shop was responsible.

In selecting a state commission to make an exhaustive study of the tax system of West Virginia and to report its findings and recommendations to the next session of the Legislature, Governor Howard M. Gore named as a member of the body Col. James Elwood Jones, of Switchback, vice-president and general manager of the Pocahontas Fuel Co. and one of the best known coal men in the state. Another member, Republican National Committeeman V. L. Highland, although nominally engaged in the banking business, is extensively interested in coal-mining properties. E. H. Arnold, of Elkins, another member of the new body, is an attorney at Elkins, but also has been engaged as an operator as head of the Randolph Colliery Co.

The Marion Division of the Bethlehem Mines Corp. in December will load the largest monthly tonnage since it began to work on a non-union basis, according to N. A. Emslie, division superintendent, who says that about 80,000 tons will be mined. Output, he predicted, would reach 100,000 tons in January. The Preston division, which embraces mines along the M. & K. R.R., broke all records last month, and it is predicted that a higher mark will be set this month.

The Davis Colliery Co., of Elkins, of which John T. Davis is president and T. B. Gross is secretary, is building a new tipple at its mine at Gilmer, in the Gilmer county field, and is equipping the mine with a shaker screen outfit and loading boom and also is enlarging its boiler capacity. The company expects to have the new tipple in commission soon after the first of the year. Four sizes of coal will be prepared—lump, egg, nut and slack, in addition to mine-run. In order to load several sizes simultaneously, track changes are being made under the tipple.

## CANADA

Six Drumheller (Alta.) miners recently convicted of unlawful assembly during the strike of last summer and five others found guilty of besetting the A. B. C. mine, who were given varying terms of imprisonment have been granted new trials by the Alberta Appeal Court.

Coal loadings on Canadian railways for the week ending Dec. 5, according to the Dominion Bureau of Statistics, showed a decrease of 2,488 cars, loading in the Western division being lighter by 1,375 cars and in the Eastern division by 1,063 cars.

## Traffic

A new regulation of the Erie R.R. provides that the company will absorb the Pennsylvania R.R. switching charge of 38c. per gross ton on anthracite when delivery is made to consignees having private sidings on the Pennsylvania R.R. at Elmira, N. Y.; effective Jan. 7, 1926.

## Obituary

**H. C. Clevenger**, coal traffic manager at Pittsburgh, for the Pennsylvania R.R., died of heart disease, Dec. 17, in his office at Pittsburgh. He was born in Philadelphia, Oct. 17, 1873 ,and spent much of his railroad career of thirty-four years in that city. In 1911 he became coal freight agent of the Pennsylvania R.R., with headquarters at Philadelphia. On the return of the railroads to corporate management in March, 1920, Mr. Clevenger became coal freight agent at Pittsburgh. He was promoted to coal traffic manager a few weeks ago.

**Gust. Johnson**, president of the Western Fuel Co., Osage City, Kan., and the oldest original director of the Osage County Bank, died there Dec. 4. He is survived by his wife, two sons and three daughters.

**Hiram P. Crouse**, 63, for over five years Cincinnati correspondent for *Saward's Journal*, and well known to the trade and operators in the south eastern Kentucky and southern West Virginia fields, died Dec. 15 after an illness of five weeks. He was former publisher of the Findlay *Republican* and the Toledo *Times*, was chairman of the Ohio Republican central committee in 1896 during the McKinley campaign, assistant telegraph editor of the *Commercial Tribune*, Cincinnati, and later held a responsible position with the Union Central Life Insurance Co.

## Coming Meetings

**Chicago Wholesale Coal Shippers' Association.** Annual meeting, Great Northern Hotel, Chicago, Ill., Jan. 6, 1926. Secretary, G. H. Merryweather, Temple Bldg., Chicago, Ill.

**American Wood Preservers' Association.** Annual meeting, Jan. 26-28, 1926, at Cleveland, Ohio. Secretary, E. J. Stocking, Chicago, Ill.

**Coal Club of Philadelphia.** Annual meeting, Jan. 28, 1926, at the Bellevue-Stratford Hotel, Philadelphia, Pa. Secretary, C. K. Scull, Philadelphia, Pa.

**Northeast Kentucky Coal Association.** Annual meeting, Jan. 28, 1926, at Ventura Hotel, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

**American Institute of Electrical Engineers.** Annual convention, Feb. 8-12, 1926, at Engineering Societies Bldg., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

**American Institute of Mining and Metallurgical Engineers.** Annual meeting, Feb. 15-17, 1926, at Engineering Societies' Building, New York City. Secretary, Dr. H. Foster Bain, 29 West 39th St., New York.

**The Rocky Mountain Mining Institute.** Winter meeting, Feb. 23-25, 1926, at Albany Hotel, Denver, Colo. Secretary, Benedict Shubart, Boston Building, Denver, Colo.

## New Companies

**The C. W. Wells Coal Co.,** Whitesville, Ky., capital $25,000, has been chartered by C. W. Wells, W. Minter and John M. Wells.

**Sunbeam Coal Co., Ltd.,** of Calgary, Alta., Can., has been incorporated to develop and operate coal and other mines with a capital of $100,000 by John L. Milligan, Gladys L. Milligan, Wm. J. Cameron and others.

**The Madeleine Smokeless Coal Co.,** capital $100,000, has been organized to operate in the southern portion of Raleigh County. Incorporators of the new company are Ashton File, W. W. Goldsmith, L. L. Scherer, C. B. Helmintoler and Helen L. Coleburn, all of Beckley.

**Welsh Coal & Transportation, Ltd.,** of Montreal, Que., has been incorporated to produce, manufacture and deal in coal, fuel and byproducts, with a capital of $50,000. The incorporators are Joseph A. Marion, Rosario Richer Roger Pillard and others.

## Publications Received

The name of the **"Mining Catalog, Coal Edition"** has been changed to **"Keystone Catalog, Coal Edition,"** with its 1925 edition, which was issued recently.

**Silicosis Among Miners,** by R. R. Sayers, Bureau of Mines, Washington, D. C. Technical paper 372. Pp. 24, 6 x 9 in.; illustrated. Price, 15c.

**Kansas Coal.** Part I, **Occurrence and Production,** by C. M. Young, and Part II, **The Chemistry of Kansas Coal,** by H. C. Allen. Engineering Bulletin No. 13 and Chemical Research Division Bulletin No. 4. University Engineering Experiment Station, Lawrence, Kan. Pp. 202; 6 x 9 in.; illustrated.

**The Mineral Resources of Manitoba,** by R. C. Wallace. Industrial Development Board of Manitoba, Winnipeg, Man., Can. Pp. 48; 6 x 9 in.; illustrated.

**The Smith Seam of the Lancashire Coal Field.** Physical and Chemical Survey of the National Coal Resources No. 5 of the Fuel Research Board, Department of Scientific and Industrial Research, Westminster, London, England. Pp. 32; 6 x 9½ in.; illustrated. Price, 1s. 6d. net.

**Power-Plant Lubrication,** by W. F. Osborne. McGraw-Hill Book Co., 370 Seventh Ave., New York City. Pp. 275; 5½ x 8 in.; illustrated. Price, $3. A practical book for the power-plant engineer, explaining the physical and chemical properties of lubricants, their action under changing influences of heat, pressure, etc., and the methods of determining their relative value.

# New Equipment

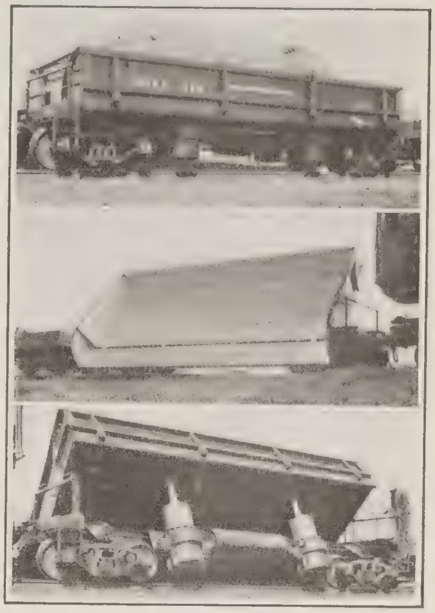
## Air Operated Dump Car Throws Load Away From Track

Of special interest to those engaged in stripping operations, the reclamation of culm banks or other similar operations requiring the handling of large volumes of material over comparatively short distances is the new air-dump car manufactured by the Differential Steel Car Co., of Findlay, Ohio. This is constructed in two standard sizes, namely, 24 and 30 cu.yd. It is of all-steel construction and the center of gravity is low, giving great stability in transit. The total height of this car is only 7 ft. 4 in. above the rail. Side boards are 2 ft. 6 in. high making the height from rail to car floor 4 ft. 10 in.

In this car the box rides on four points of support above the bolsters. When dumping, therefore, the car box does not tilt about a central point but about one or the other line of trunnions upon either side. The side boards are hinged at the bottom and fold down to the plane of the floor during the dumping operation. The action of the dumping cylinders is cushioned at its completion so that no stress is imposed upon either car, track or supporting trestle and the material discharged is thrown well in the clear. No locking mechanism to hold the car box in an upright position is necessary.

Advantages claimed for this car by the makers include the following: Its low height affords stability and easy loading. The design is simple, affording ruggedness of construction. Inasmuch as the body rests on four supports directly over the bolster side bearings, great stability is attained and all locking devices rendered unnecessary. Any size of material that can be handled by a steam shovel can be dumped to either side merely by the proper throw of a lever. A whole trip can be discharged simultaneously to either side or any portion of it to one side and the balance to the other side from any car of the trip. The load is dumped clear of the track; the sector plate on the end of the side board prevents spillage and fouling of the track ballast. The flat, smooth bottom of the car allows clean discharge of even quite sticky material such as clay. The movement of the body during discharge imparts a definite throw to the material without shock. Shoveling of the material discharged is eliminated and in most cases the use of a spreader is unnecessary.

Numerous transverse sills support the bottom of this car. As a result the box is admirably adapted to the handling of large pieces of material and the rough treatment to which dump cars are invariably subjected. Cars of this type have been used for some time on the Mesabi iron range where they have given excellent satisfaction. They will be particularly useful in the coal industry in strip pits where the spoil must be hauled to bank. They will prove useful also in those pits where the spoil is overcast, and the coal is loaded by shovel but passed through a preparator before being shipped to market.



**No Shovel or Spreading Necessary**

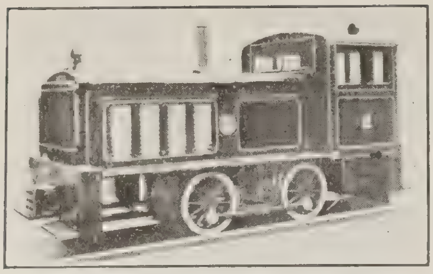
In the upper view the loaded car may be seen ready to discharge its load. In the second the load has been dumped, sliding clear of the ballast so that no shoveling or spreading is necessary. The lower illustration is a rear view of the car in its dumping position. Note the numerous cross sills supporting and strengthening the floor plate.

## New Gasoline Locomotive Has Spring Draft Rigging

In the accompanying illustration may be seen the new 12-ton gasoline locomotive recently placed on the market by the Vulcan Iron Works, of Wilkes-Barre, Pa. This machine is known as the Class EW-12 and is similar in general design and construction to the other worm drive machines developed by the same builder during recent years. All of these locomotives embody cast-steel frames, steel tired wheels, worm drive on the rear axle with side rod connection to the front drivers and a constant mesh transmission gear.

The 12-ton model here illustrated is equipped with a 100-hp. Waukesha motor fitted with Ricardo head. It has four speeds forward and an equal number in reverse. The actual speed along the track ranges from 2$\frac{3}{10}$ m.p.h. in low gear up to 12 m.p.h. in high. The drawbar pull in high gear is 2,275 lb. with a starting pull in low gear of 7,200 lb.

This locomotive may be built in any ordinary track gage up to standard and can be adapted to any haulage service. On account of its great power and



**Sturdily-Built Car Switching Unit**

This machine which weighs 12 tons is fitted with a 100-hp. motor. When equipped with spring draft rigging and M.C.B. couplers it is especially adapted to switching railroad cars. The spring draft rig protects the motor and other parts from the shocks of bumping and pulling and assures a long life.

sturdiness, however, this machine is particularly suitable to standard-gage switching work. For this gage the standard model is fitted with a spring draft rig and M.C.B. couplers. This rig is so designed as to take up in the bumper all the shocks of coupling, together with the stresses of pulling and pushing railroad or other heavy cars. The motor and other working parts are protected by the spring draft rig and a long life is assured.

## Electric Speedometer Can Be Installed Anywhere

Tachometers are well-known instruments about the mine. In a broad sense, they range all the way from the simple hoist indicator or the speedometer used on the company automobile or truck, to the device that indicates the r.p.m. of the big turbine in the power plant. Heretofore in practically every instance it has been necessary that the indicating dial or scale of the instrument be located comparatively close to the machine whose speed it measures. That is, within reach of a chain, a belt or a shaft. The Electric Tachometer Corp., of Philadelphia, Pa., recently has developed a device of this kind that is subject to no such limitations and may be placed anywhere within hundreds or even thousands of feet of the machine whose speed it indicates.

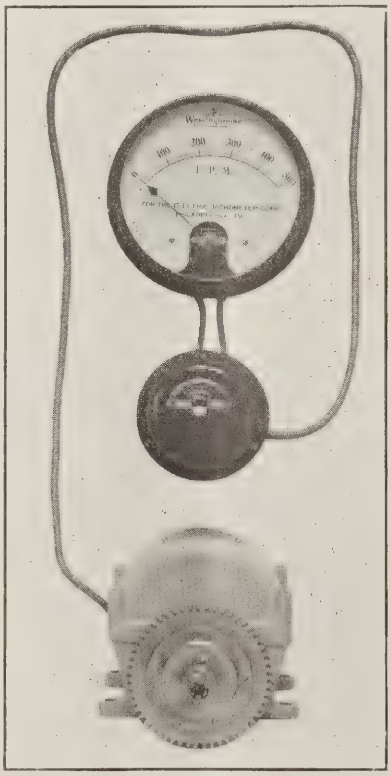
This tachometer consists of a magneto-generator driven positively from the shaft of the machine, the speed of which is to be measured. This generator has the property of producing a voltage exactly proportional to the speed of the driving shaft. It is, therefore, a simple matter to calibrate a voltmeter in either revolutions or feet per minute corresponding to the speed of the shaft or the travel of a hoisting cable. This voltmeter which has either a 7½- or 9-in. dial can be furnished with any scale desired. Thus far the maximum rope speed of hoist for which these tachometers have been calibrated, has been 1,500 ft. per minute. The usual practice is to furnish indicators with a central zero point, so that hoist speeds can be read in either direction.

One of the chief advantages of tachometers of this kind is that the indicating instrument can be removed from the source of energy by almost any distance whatsoever. Thus the indicator may be connected to the magneto by several hundred feet of cable. This makes it possible to place the indicating instrument where it is most desired and where its usefulness will be a maximum, as well as where it will be thoroughly protected from all outside interference.

With this indicator and magneto is provided a rheostat by means of which the reading of the instrument may be corrected in case it becomes inaccurate, or in case the drive ratios for the magneto are changed.

This tachometer lends itself to a variety of purposes, but in many cases such as where the instrument is attached to a motor shaft, turbine, stoker or other machine, it is advantageous that the scale shall read in revolutions per minute. On the other hand, belt speeds, conveyor travel and the like may well be indicated in feet per minute, while the speed of locomotives may be read directly in miles per hour. On the other hand, if attached to an electric generator the instrument may be calibrated to read in cycles per second.

Heretofore, where instruments of this general type, that is, those intended for indicating the speed of various machines, have been employed, it has been necessary to mount the instrument either on the machine itself or close at hand. With this new electric tachometer, it becomes perfectly possible to attach the magneto to the hoist drum shaft, place the rheostat upon the wall of the hoist house and the indicator in the superintendent's office several hundred or possibly thousands of feet away.



**Voltage Is Proportional to Speed**

By connecting the magneto positively to the machine the speed of which is to be indicated and making its voltage proportional to its speed the voltmeter which acts as the real indicator may be placed at any point desired. Hundreds or even thousands of feet may thus separate these two instruments.

## Industrial Notes

At a recent reorganization, the Joy Machine Co., was taken over by the **Joy Manufacturing Co.**, of Franklin, Pa., which will continue the manufacture and sale of mechanical coal loaders. All rights to coal-loading and allied machines heretofore invented by Joseph F. Joy, of Pittsburgh, Pa., and to all subsisting patents covering such machines in the United States, Belgium, France, Great Britain, Austria, Australia, Canada and Germany, together with all pending applications in said countries and the patents to be issued thereon, have become the sole property of the Joy Manufacturing Co.

**The Erie Electrical Equipment Co.**, Johnstown, Pa., announces the appointment of the **Universal Electric Sales Corporation** with offices at 30 Church Street, New York; 11 Beacon Street, Boston, and 332 Healy Building, Atlanta, Ga., as representative in the states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, eastern Pennsylvania, New Jersey, Delaware, Maryland, Virginia, North Carolina, South Carolina, Georgia, Florida, Tennessee and Alabama.

**Charles M. Schloss** has been admitted to partnership in Lindrooth, Shubart & Co., manufacturers' representatives in Denver, Colo.

**The Babcock & Wilcox Co.** announces that it has purchased the **Fuller-Lehigh Co.** and its subsidiaries, manufacturers of pulverized-fuel and cement-mill equipment as well as the **Bailey Meter Co.**, manufacturers of meters and recorders, combustion-control equipment, pulverized-fuel feeders and water-cooled furnace walls. The Fuller-Lehigh Co. and the Bailey Meter Co. will be operated with the same organizations as heretofore, with the exception that Col. J. W. Fuller will become chairman of the board of the Fuller-Lehigh Co., E. G. Bailey will become president, and A. E. Douglass, of Fuller-Lehigh Co., will become vice-president in charge of sales. Mr. Bailey will continue to act as president of the Bailey Meter Co. and R. S. Coffin will continue as vice-president and general manager. By the acquisition of these companies the Babcock & Wilcox Co. will be able to offer boilers, superheaters, economizers, air heaters, chain-grate stokers, oil burners, pulverized fuel equipment, water-cooled furnace walls, meters, and combustion control equipment; all in any combination that may be required to supply complete steam generating units.

**The Oxweld Acetylene Co.**, 30 East 42nd St., New York City, announces the appointment of J. N. Walker as general sales manager. L. D. Burnett has been appointed Eastern department sales manager to succeed Mr. Walker, and Z. T. Davis, Jr., is now filling Mr. Burnett's former assignment as assistant sales manager, Eastern department.

## Trade Literature

Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., has issued a 41-page book on its **Engineering Achievements for the Year 1925.** The book is well illustrated and covers a diversity of subjects.

**Type D-54 Mechanical Drive Turbine** is the title of the four-page bulletin GEA-197, recently issued by the General Electric Co., Schenectady, N. Y. Describes the operation of this turbine, which is intended for the driving of centrifugal pumps, blowers and other classes of mechanical drive.

## Peace or War?

AFTER NEARLY FIVE MONTHS of long-distance sharpshooting, anthracite operators and union spokesmen for the miners again face one another across the conference table. The issues to be decided are the same as when John L. Lewis, president of the United Mine Workers, abruptly terminated the joint conferences at Atlantic City on Aug. 4. Neither side has publicly receded from its interpretation of the factual questions involved in the union's demands. Both sides still challenge their opponents' interpretation of those facts.

In the weary weeks of alternating hope and despair which have intervened, however, there has been time for reflection, time to test the temper of the contestants. There has been time, too, to study the drift of public opinion and to weigh the strategy so far pursued in the cold light of actual results achieved. The idle miners already have lost in wages more than three times the annual increases written into their demands. The spirit of holiday adventure in which they laid down their tools has vanished. An empty Christmas, depleted savings and increasing actual want—that is the price they have paid for following leaders who elected to wage war where honorable peace was offered.

No more successful leader than John L. Lewis ever has guided the destinies of the United Mine Workers. He has wrung victory from situations in which less bold captains would have acknowledged defeat. But his strategy in the anthracite strike has everywhere met with disaster. His attempts to scare the public into a belief that the householder would freeze to death if the anthracite mines were closed left the public apathetic—or hostile. His attempts to stampede the federal government into intervention with the threat of a general bituminous strike resulted only in government action opening up eastern states to the non-union coals of West Virginia. The public, to be sure, has been inconvenienced, but it is his own followers in the anthracite region who have been the real victims of Mr. Lewis' campaign.

If he so wills, Mr. Lewis can perhaps continue the struggle much longer. It is in his power to inflict further heavy financial losses upon the operators. But in the exercise of that power, he must bleed white the workers who have placed loyalty to the union organization above cost and above sacrifice. Conceivably such a course might be justified if the alternative were abject surrender. No such alternative, however, confronts the union. The peace proposals of the operators are not, as some people would like to believe, one-sided. In offering arbitration in place of a war of exhaustion, operators risk as much as the miners. They risk a decision which might award the union the check-off against which the operators have railed as bitterly as have the union leaders against arbitration. They risk, too, the possibility of a decision which would increase wages.

Obviously, if miners and operators cannot agree among themselves as to the facts involved and their bearing upon the demands made, the sensible thing to do is to submit the case to a third party for decision. This is the rule of enlightened civilization. Of course, it means arbitration; and arbitration, once a constitutional aim of the United Mine Workers, is anathema to the union leaders. Mr. Lewis has had his fling at war. He will show real leadership if he now inclines to honorable peace.

## Our Rail Problem

SOME OF OUR many operators—the successful ones—are taking a serious view of the transportation problems of the mine, and subjecting mine-haulage questions to the light gained from a study of railroad operation. What railroad company delivers cars without thought of whether they can be used, or lets the engineer feel his way along the road without signals or direction, or permits the making up of trains without regard to definite standards determined for the haulage equipment supplied? And what coal mine with a large tonnage can afford to neglect the precautions that every railroad takes?

In a metal-mine, perhaps, where there is discipline and men invariably come to work unless sickness supervenes or prior notice has been given—where also, as the men are not dependent on each other but do their work without a division of labor into cutting, scraping, shooting and loading, and are never ruled out of their places because of the presence of methane, it might be possible to route mine cars to any given section of a mine without ascertaining how many men are out and how many cars are necessary; but in coal mining that is not so. Especially is this true in the evening, when the motormen run around unexpectantly looking for enough cars to justify their having started on another trip. Thus they waste time when they should be laid off, because all the men whose behests they serve have gone home long before.

With a dispatching system the dispatcher knows where cars are needed and when. The trips are switched where they are wanted, often before word arrives at the office that the men in 10th left are at a picnic, a christening or a sheriff's sale, or that the cutters in that heading had a burnout and failed to cut several places in the preceding night, or again that the fireboss marked for danger several of the rooms in that heading.

With such a system motormen do not stop and waste time trying to ascertain if the road is clear. The dispatcher has a definite knowledge of just where the trips are, and moves the cars in accord with that information. He is able to tell just where the coal is coming from and accordingly can detail to the foreman where he would do well to proceed to correct any lag in tonnage. As a rule all cars look alike to the weighman. Without a tedious analysis, an examination of the weigh sheet gives no information as to the section that is failing to measure up to the tonnage requirements. A dispatcher's record of cars supplies that defect and gives to the foreman a quantitative story of the status of each section.

With mines producing up to about 13,000 tons daily, with hauls up to five miles, and with small cars rarely exceeding five tons capacity per car, the mines have a big railroad problem. It will be solved according to approved transportation standards, and not in the haphazard manner that marked the era of the mule skinner.

## An Outside Summary and Viewpoint

IN A QUESTION so complex as that of the industrial factors underlying the coal industry, even those who are closest do not agree as to the ills and the remedies. Those who are entirely outside the industry, but to whom the coal question is one of interest, as touching their private affairs at many points, are less well informed and less able to judge; nevertheless, they do the best they can, and of such public opinion, the most potent, perhaps, of modern influence is formed. As an example of such trends of opinion is an article by Arthur E. Suffern in the December issue of *Atlantic Monthly*, an article which endeavors to be guarded and balanced, and to abstain so far as possible from judgment, after having stated the history of coal troubles and the opposing contentions. We quote from this article without comment or approval: The article states in a preliminary that "the failure of nineteen coal companies and a union representing over 160,000 anthracite miners to come to an agreement upon wages, hours, and working conditions faces millions of people with the prospect of a shortage of fuel, inadequate heating facilities, and high prices." And the writer adds, "In every controversy there are two sides to be heard. Both sides have a story to tell and a cause to defend. The people who want an uninterrupted supply of coal should not be an interested public. One-sided condemnations of either the miners or the operators will not control the conditions that cause strikes." After stating at length the case on both sides the writer observes:

"However, the placing of mere abstract rights in opposition will not solve the problem of equity in wages, profits, and prices to the consumer. Nor will it curb the abuse of power that may be practised by the miners, the operators, or the public. The more the strike is prolonged, the less likely is the prospect that an equitable adjustment will be made, because pressing conditions will probably bring a forced settlement." And in the summary of the case, the author first ventures a personal opinion:

"Whether a settlement is made in joint conference or by a commission, comprehensive data on costs, prices, and profits is a prime need for the coal industry. Otherwise there is no basis of arriving at equity between the miners, the operators, and the consumers. Such data need to be collected from year to year by the Government under conditions that will make the data dependable. They can then be used with authority by the miners and operators in joint conference in arriving at voluntary agreements or by commissions in arbitration proceedings. If the operators and miners desire to settle their affairs without the aid of the Government, they stand in the best position to do so when all the cards are on the table.

"To deal with the present crisis and to establish more constructive industrial relations for the future requires a new order of statesmanship. If the leaders on both sides have the statesmanship to introduce a co-operation between the management and the union, similar to that which is in operation on certain railroads with the railroad shop-crafts, the first requisite for that end will be reliable data from year to year on actual conditions in the coal industry."

## In Praise of Partisanship

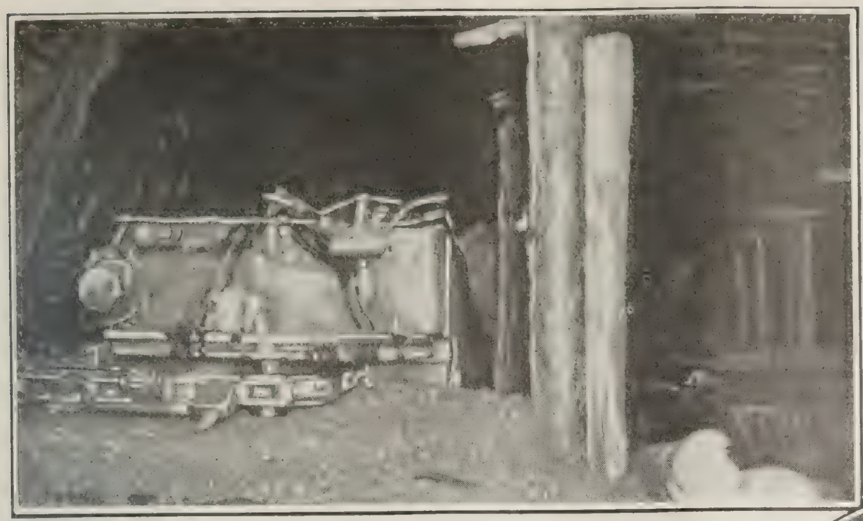
THERE ARE TIMES when nothing is so conducive to justice as a lusty partisanship. The process of balancing one contention against another can be drawn out to such a fine point that labored impartiality becomes more harmful than helpful. In a meticulous desire to omit the presentation of no fact which will support one side or the other in an economic controversy there is always the danger that the public may become so confused by the minutiæ that broad fundamentals are obscured. "A plague o' both your houses" then becomes the public's substitute for a discriminating judgment.

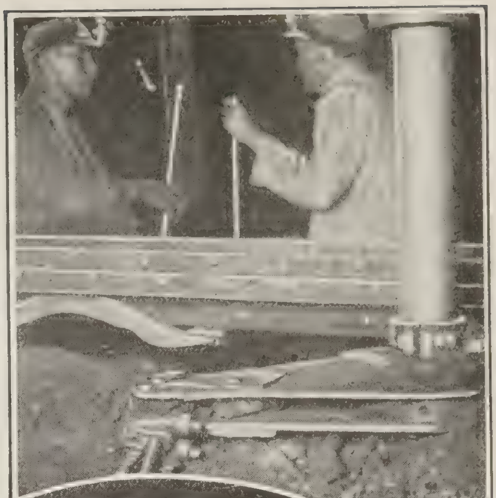
This is the danger that dogs the present anthracite situation. A President rightly condemns "the perennial conflict" in the coal industry, but neglects placing the blame for the existing suspension. A close student of labor relations in the coal fields makes a succinct summary of the hopes and aspirations of employers and employees in the hard coal region and then calls for more "facts" as a basis of settlement. A group of eminent economists and engineers warns the industry that there can be no abiding peace until a joint agency attacks the technical problems of management. All of these unprejudiced critics shrink from asking the public to take sides.

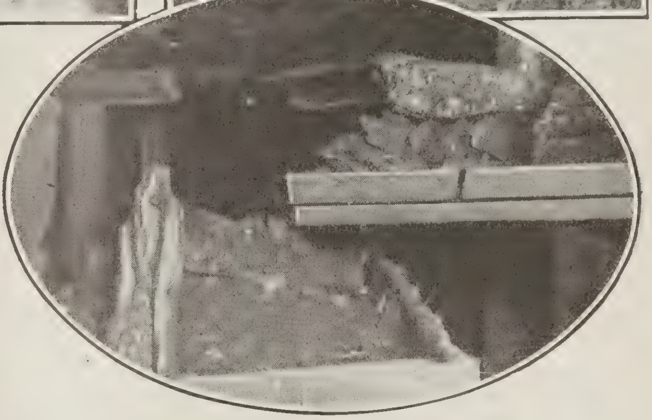
Were there a necessity for the public to pass judgment on the conflicting statistical claims of the contestants, this scrupulous regard for impartiality would be understandable. But no such task is imposed upon the public. The issue is much simpler. All the public is asked to do in its own behalf and for its own protection is to single out the contestant that blocks the approach to a peaceful solution. That question determined, it becomes an easy matter for the public to register its disapproval of such an attitude. This decision cannot be reached, however, through any indiscriminate damnation of the industry as a whole. Operators and miners must be considered separately, and the blame assessed where it belongs.

If that discrimination is exercised, there will be no difficulty in making the assessment. From the start of the negotiations the operators have offered unrestricted arbitration of all issues upon which they cannot agree with their employees. Their position is unchanged. From the start the union leaders of the miners have rejected that offer. Insisting upon the justice of their demands for higher wages and changes in working conditions, they have repeatedly refused to submit their cause to arbitration. The public, of course, can draw its own conclusions.

"A strike in modern industry," said Calvin Coolidge recently, "has many of the aspects of war in the modern world." Those who love industrial peace, whose comfort and whose pocket-books are hit by industrial war, however, do not help the cause of peace when they condemn both the aggressor and the aggrieved with equal vehemence or even when they withhold judgment. We need not alone lip service to the principle of arbitration, but a courageous decision in favor of industrial disputants who stand for that principle.







# Jigging Conveyors Used On Long Walls Make Output Sure

## Alabama Mine Works Five Faces for Two Years with Shaker Chutes—Gob Helps Control Roof Subsidence

**By J. H. Edwards**
Associate Editor, *Coal Age*
Huntington, W. Va.

ALL KINDS OF MINES and mining systems may be found in Alabama—strip pits, drifts, slopes, shafts; in thick beds and in thin beds, at all inclinations from horizontal to steeply pitching; room-and-pillar, long face and longwall, running the entire gamut of mining conditions. But if one were to describe to the average operating man the various interesting mines of this state and then ask him which of them he would rather see with his own eyes, the chances are strong that he would reply: "That Aldrich mine of the Montevallo Coal Mining Co. where they are working five 325-ft. longwalls by means of shaking conveyors."

The fact that so few American mines operate on a true longwall system and that few if any employ face conveyors equaling in length those used at Aldrich, makes this operation stand out as being unique among those of the country at large. And yet, neither the longwall system nor the use of face conveyors are new at Aldrich. The mine was switched from the room-and-pillar system to longwall in 1906 by P. B. Thomas, father of D. A. Thomas who is now president and manager of the company and who, so to speak, has ironed out the kinks and wrinkles and has put the mine on a paying basis. Practically 100 per cent recovery, 67 per cent being lump, and a cost substantially below that of the room-and-pillar method makes it obvious that the "big three" have been cornered at Aldrich.

This mine, about the most southern in Alabama, is located on the edge of the Cahaba field, 45 miles by rail from Birmingham. The coal is that of the Montevallo bed, which, generally speaking, lies on a pitch of 12 to 15 deg. A typical section is shown beside Fig. 2. The working height is roughly 50 in. in which is included from 14 to 18 in. of rash. The coal is a high-grade bituminous used chiefly for domestic purposes.

### WORKED THROUGH SLOPE FOR 21 YEARS

Opened in 1885, the mine was worked through a slope on the room-and-pillar system until 1906. Levels were turned off the slope every 200 to 300 ft. and rooms were driven up the pitch. After the slope had been advanced approximately 2,500 ft., and about the time that longwall operation was well started, it was found that the slope was running into a basin a few hundred feet wide. As Mr. Thomas expressed it, "had operations continued along the lines projected they would soon have met themselves coming back." Accordingly, a change was made and walls advanced to the rise. Since then they have been worked at various angles to the pitch.

As the scrap heap on the surface at this mine will testify, the present conveyor was not the first one tried on the longwall faces. It was preceded by a sectional chain machine of rather heavy and expensive design. The shaking chute now employed was evolved by a series of changes extending over several years made in

---

The illustration at the left in the headpiece accompanying this article shows a longwall machine undercutting a face. The bar of this machine is only 4 ft. long, this length having been found to be most advantageous. One such undercutter is used on each face. In the upper illustration to the right may be seen the bellcrank and side of the conveyor as well as the jack holding the the bellcrank in position. The motor-operated shaking engine is stationed some distance to the side of the conveyor, which it drives through the medium of a cable that may be seen at the bottom of the picture. The oval shows the conveyor discharging to a mine car on the heading. This passage is kept well ahead of the advancing face and bottom is lifted on it so as to afford ample room for loading the cars to full capacity.

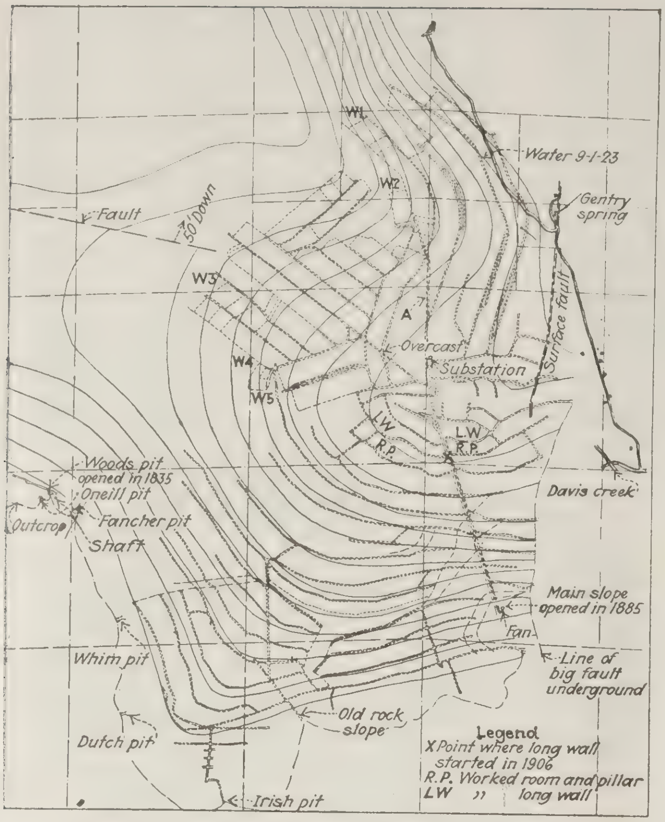


Fig. 1—Map of the Montevallo Coal Mine

This mine originally was laid out for room-and-pillar operation, but when it was found that the main slope was running into a basin of small extent the plan was changed and the longwall system adopted. Faces have since been worked at practically all angles to the pitch. The position of the present faces are indicated by $W_1$, $W_2$, etc.

the design of an original Mavor & Coulson outfit imported from Scotland.

Fig. 3 shows the four principle parts of the conveyor proper. In the foreground is a floor cradle and roller, back of which is a drive section of the trough or pan, and in the background is a common, or plain, section. This latter is one that has just been brought to the shop for repairs. A hole has been worn in the bottom and the sides are bent out of shape. The riveted splice in the center indicates that this section was, sometime before, built in the shop from two parts in fairly good condition cut from worn or damaged sections.

All sections of this conveyor are 9 ft. long. Originally ⅛-in. steel plate was used in their construction, but because these soon failed a change was made to $\frac{3}{16}$-in. plate. Two men can easily pick up and carry a section. The drive pan or segment is somewhat heavier than the others, due partly to its more sturdy construction and partly to the projection or fitting on its under side into the holes of which the connecting rod of a bell crank is fastened. The illustration at the upper right in the headpiece shows a drive section with the bell crank and its anchoring roof jack in place. In the left foreground is the wire rope which extends from the bell crank to the walking beam of the actuating motor-driven shaking engine.

Details of this engine are shown in Fig. 6 while Fig. 7 is an end-view photograph of it. The drive is by means of a 27-hp. direct-current motor. As the conveyor is moved forward after each cut the ⅞-in. drive rope is lengthened by readjusting in the connecting-rod clamp seen in the foreground. By this arrangement the engine is left in one place while the wall is advanced 50 to 100 ft., or more, as conditions may warrant.

The engine location with respect to the conveyor is indicated in Fig. 2. Here the conveyor is shown in a position about 5 ft. from the face, to which location it has been moved preparatory to loading out the cut. On the day before, when loading out the previous cut, it was in the position *A* indicated by the dotted lines.

## Roof Control Presents Problem

Roof conditions in the Aldrich mine, no doubt, are favorable to longwall operation but, nevertheless, it required years of costly experience to find an adequate method of control. Overlying the coal there is from 30 in. to 15 ft. of draw slate, above that 50 to 75 ft. of sandstone, and then perhaps 100 to 125 ft. of conglomerate. The total depth of cover ranges from 435 to 800 ft.

The action of this roof is remarkable. The walls, each 325 ft. in length, are worked advancing. Cutting is done in the bottom rash with a machine having a 4-ft. cutterbar. Machines with bars of greater length up to 6 ft. were tried but it was found that a 4-ft. cut is all that consistently can be cleaned up each shift. The machine used is of the longwall type and is mounted on a sled and adjusted to the proper height to cut the parting. Six to eight sets of bits are required in cutting each wall.

Bugdust, rash, and slate from the bed are shoveled over behind the conveyor into the gob. Most places contain just about enough of this refuse to fill the gob to the roof. Where the quantity is inadequate soft cribs (not filled with rock) are built on top of it and left in place to ease the roof down in its settling process. Breaks occur every 200 to 600 ft. unless a rift in the sandstone is encountered. Such a contingency causes a great deal of trouble and much extra expense for cribbing and timbering.

The loading entry or road at the lower end of each

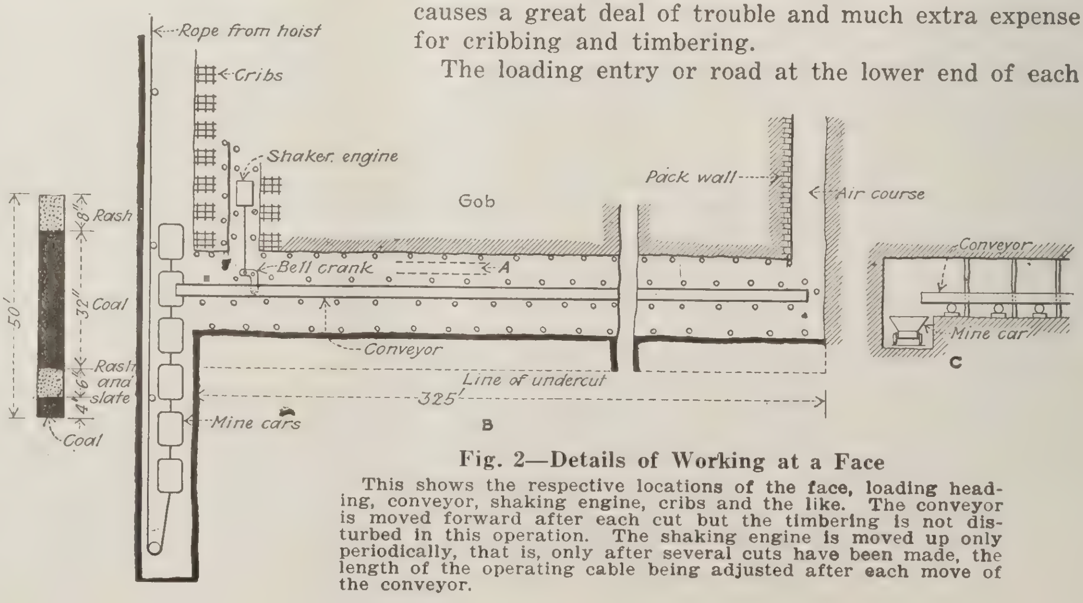

Fig. 2—Details of Working at a Face

This shows the respective locations of the face, loading heading, conveyor, shaking engine, cribs and the like. The conveyor is moved forward after each cut but the timbering is not disturbed in this operation. The shaking engine is moved up only periodically, that is, only after several cuts have been made, the length of the operating cable being adjusted after each move of the conveyor.

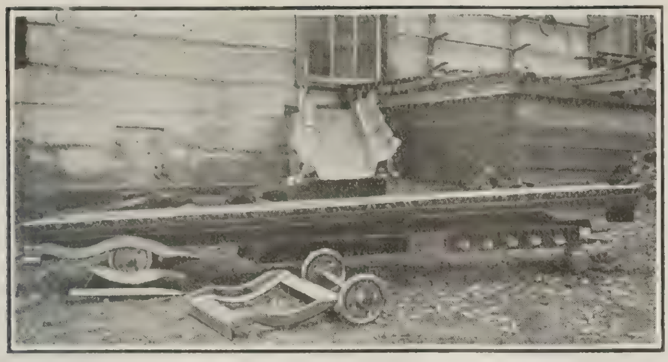

**Fig. 3—Four Main Parts of the Shaking Conveyor**

In the foreground may be seen the curved angle-iron track and a pair of the rollers that support the conveyor pans. Behind these is a drive section that receives reciprocating motion from the bellcrank and transmits it to the balance of the conveyor. In the background is an ordinary pan section. The particular section here shown has been sent to the shop for repair. As may be seen a hole has been worn completely through it at its upper end and it is badly bent and battered.

wall is kept about 100 ft. ahead of the face. Bottom to the extent of 4½ ft. is lifted in order to bring the tops of the cars well below the discharge end of the conveyor. Rock-packed cribs, made of 5- to 6-in. round timbers, as shown in Fig. 4, are built to protect the entry. The air course at the upper end of the wall is kept open by brushing top, the material thus brought down being used to build a pack wall that serves also as a brattice. Because the mine generates some gas, considerable care is taken to keep the ventilation at the faces up to standard. Open lights are used exclusively in this mine.

Fig. 9 shows how, at the point *A* on the map, the roof has subsided during nine years compressing the 50-in. gob to an 18-in. mass packed as hard as the coal itself. The haulageway on which this photograph was taken was driven three years ago through the gob of a longwall face that was worked six years earlier.

### Much Timber Used at the Face

Timbering at the face is done with 5- to 6-in. posts set on 4-ft. centers. None of this material is recovered. Where tender roof is encountered cross timbers or straps are employed. On the wall (marked $W_2$ on the map) where the photographs accompanying this article were made, each new row of timbers is doubled, ahead of the conveyor, after each successive forward move. As the coal is loaded out a row of emergency or temporary props is set against the rib. These timbers are removed one at a time ahead of the mining machine and permanently reset immediately behind it, as the cut progresses. Injuries to men and loss of equipment at the face practically have been eliminated by the liberal use of timber.

Cutting along each wall progresses in one direction one night and in the opposite direction the next, the machine being left where it finishes the cut. Turning the machine around before beginning a cut is accomplished in a short time considering the limited space between timbers. The cutterbar, of course, is swung to the opposite side as the machine is turned. Five machines are used, one at each wall. Another is kept at the underground motor pit as a spare.

The sequence of operations performed by the night crew is as follows: First the daily supply of timbers is unloaded from mine cars and distributed among the 325-ft. face. As the mining machine begins the cut timber men set permanent posts behind it against the face, and double the last row previously set. At the same time a conveyor-moving gang begins work. While one man goes along removing the two ⅞x7-in. bolts that hold each section to the next, two men begin moving the 32 pans or sections, thus disconnected, to their new position.

While this is being done other men are resetting the roof jack, bell crank, and the conveyor drive section. Next the pans are bolted together, lined up and finally the floor cradles and rollers set in correct position. The alignment does not have to be perfect. One of the 325-ft. conveyors has been operated when 3 ft. out of line. Any tendency of the conveyor to buck because of bad alignment or uneven loading, is corrected by setting "rubbing" timbers to confine its movement.

### How the Conveyor Works

Before describing the experiences at Aldrich in operating on various pitches, the mechanical action of the conveyor should be explained. The conveyor is nothing more than a plain sheet-metal trough or chute of a length equal to that of the wall being worked. The entire trough reciprocates with a differential motion, the stroke being 7, 8 or 9 in. long as desired, and the speed being about 65 cycles per minute.

The rope from the driving engine, through the medium of the bell crank, moves the trough quickly, on the backward stroke. Because of the shape of the cradles this movement elevates the trough and its load to a height of an inch or more. From this position it rolls back gently by gravity carrying the coal along with it. About the time that the trough reaches the lowest point of the cradle the rope jerks it backward again and the coal because of its inertia slides forward along the trough. The material conveyod thus shuffles along, a few inches at a time with a sort of wave motion.

With proper alignment and the cradles free of dirt, the conveyor will work on the level, if it is not too long, but with the conditions at Aldrich operation was not practical on ½ per cent grades, so the walls were swung to obtain an inclination of not less than 1.25 per cent in favor of the load. The conveyors have been operated satisfactorily on grades of from 1¼ to 15 deg., the average use being on about 8 deg.

This range of action affords an opportunity to swing the walls so as to advance them at an angle to the pitch. This is indicated on the map by the various directions in which the walls have been advanced, especially in

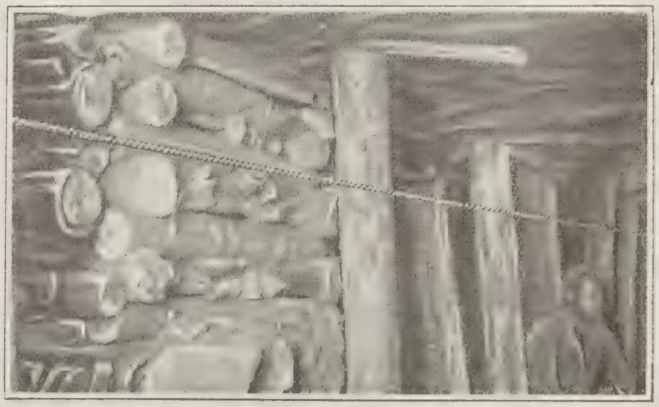

**Fig. 4—Rock-Packed Cribs on the Main Entry**

Naturally, the roof over the entry must be carefully supported. This is done by the use of both cribs and props. In this picture may be seen the cable by means of which the cars are handled on this passage.

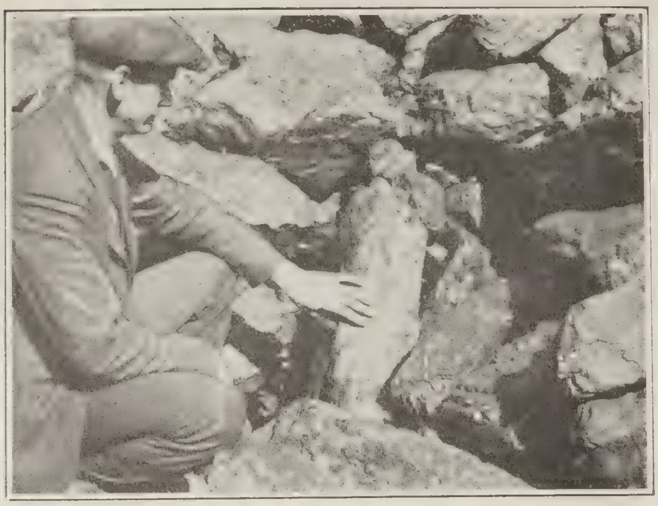

Fig. 5—Lump Coal in the Stockpile

B. C. Moore, master mechanic and outside superintendent, is here seen showing by comparison the size of the lumps in the stockpile. Sixty-five per cent of the coal produced in this mine is of lump size, used for domestic purposes. It can be sold practically always at a profit.

the vicinity of faults. The five 325-ft. walls which are now being worked are indicated by $W_1$, $W_2$, etc., on the map. The general conditions and methods vary but little from wall to wall. The inside photographs accompanying this article, except Fig. 9, were taken at $W_2$.

Experience has demonstrated that adjacent walls should be maintained either within 50 ft. of each other in order to keep the weight equalized, or should be kept over 250 ft. apart so that a fall on the leading wall will not affect the one following.

Haulage from the walls to the basin is handled by twelve single-rope hoists each driven by a 27-hp. direct-current motor. Electric locomotives assemble the trips and distribute empties in the basin at the foot of the main slope. The average weight of coal per car is 2,650 lb., and the production per wall overages about 120 tons per day.

The labor necessary for each wall is as follows: Each day-shift consists of ten loaders, one conveyor man, one timberman, one conveyor operator, two gobbers and one crib man, making a total of sixteen in all. The night shift consists of three timbermen, two conveyor movers, one machine runner, one scraper and one jack setter, making a total of eight men. Coal is shot down only as needed with 4-in. permissible powder, with no specified distance between holes. A wall does not ordinarily consume more than 25 sticks per day, including the extra number necessary for shooting tight corners.

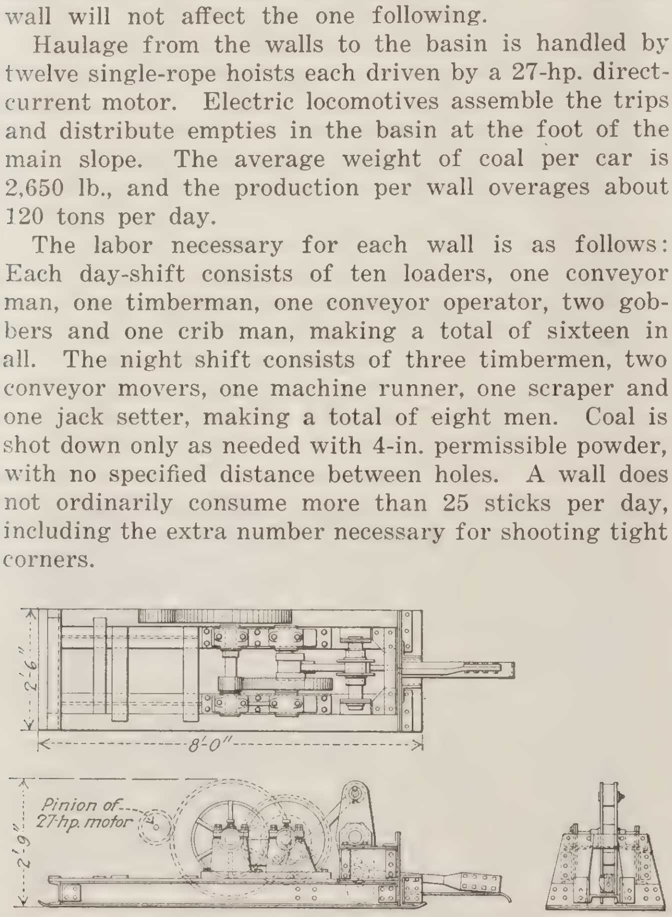

Fig. 6—Details of the Shaker Engine

Although the rotational speed of the crankshaft is uniform, the walking beam has an unequal oscillation. This, aided by the bellcrank and by gravity imparts a jigging or jerking motion to the conveyor chute.

During the last two years a remarkable record has been made at the Aldrich mine. Throughout this entire period, only five times has it proved impossible to make the regular daily advance on each of the five walls worked. These failures to load out, or to cut the face, were due either to falls on the entries or breaks on the walls. And this mine works 310 days per year! All inside labor is supplied and supervised by the state. Convicts operate locomotives, hoists, and cutting machines, as well as doing the timbering and loading at the face.

The fact that prison labor is used, of course simplifies the problem of cleaning up the walls each day. The mining company is obliged, however, to use the men every day of the year and consequently at times is compelled to stock coal at the mine. Transferring coal to the stockpile is done by placing a number of 4-ton, self-dumping boxes on railway cars, loading these at the tipple and then unloading them by means of a semi-portable, stiff-leg derrick. Coal is reloaded from the pile by filling boxes by hand and dumping in the railway cars by means of the same apparatus.

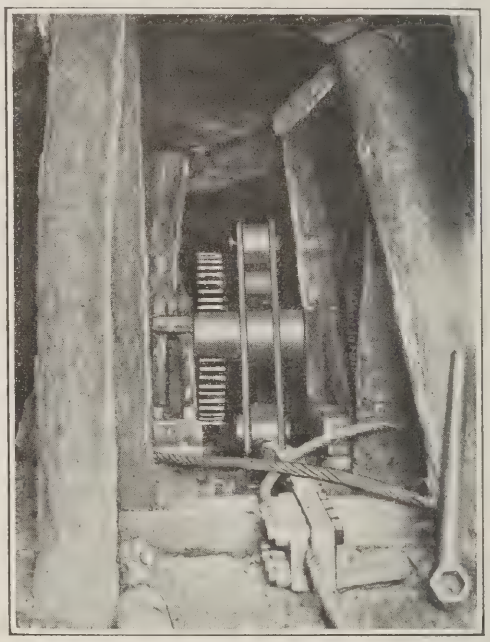

Fig. 7—End View of Shaker Engine

The adjusting clamp, by means of which the length of the cable leading to the bell crank is brought to proper length, may be seen on the end of the connecting rod in the foreground. Loosening a few bolts, lengthening or shortening the cable and tightening the bolts again effects all the adjustment that is necessary.

An interesting bit of history connected with the Aldrich mine was disclosed last year when Mr. Thomas cleaned up an old opening to the left of the present operation. This old mine is designated on the map as the Woods Pit. In it were found well-preserved relics of rather primitive mining methods. Among these were almost miniature wooden cars fitted with wooden wheels which ran on wooden rails provided with wooden frogs. Mr. Thomas states that he is fairly certain that the Woods Pit was opened in 1835. A geological report of about 1850 mentions this mine and explains that it was abandoned because of the dangerous roof. In contrast to this report, however, Mr. Thomas found the opening to have, what he would consider, a rather good roof.

The success of the last few years in operating the Aldrich mine on the longwall and face-conveyor system

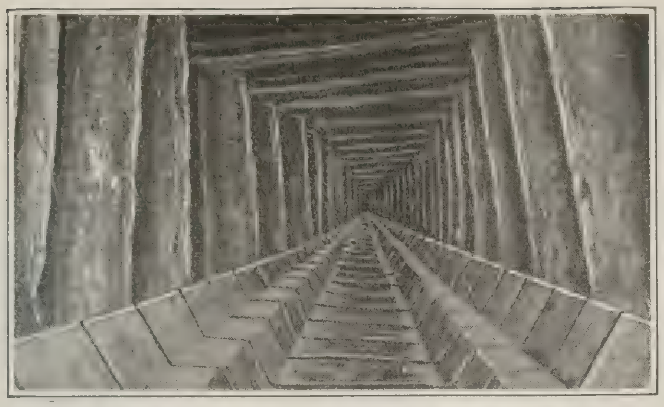

**Fig. 8—Looking Along the Conveyor Pan**

This shows the conveyor empty or ready to receive coal. Timbering along the face is heavy and in some places it is necessary to use straps or beams from prop to prop forming virtually three-piece sets over the conveyor. In case as sometimes happens, the conveyor shows a tendency to buckle sidewise, it becomes necessary to set "rubbing props" to hold it in line.

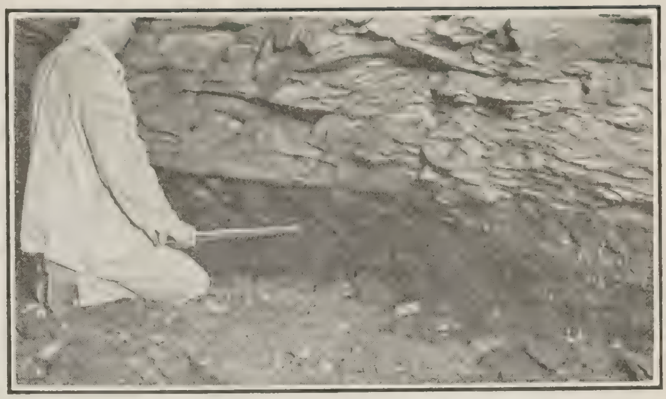

**Fig. 9—Roof Subsidence of Three Feet**

This shows J. L. Dollar, inside superintendent, demonstrating how the gob has packed to a mass as hard as the coal it displaced. At this point the roof has been subsiding for 9 yr. during which time it has settled approximately 3 ft. The haulageway where this photograph was taken was driven 3 yr. ago through a gob area that had been worked out for 6 yr.

has convinced the management that it is "on the right track." A sixth wall is now under development and considerable new equipment is being installed on the outside. Thus the steam hoist is being replaced by an 800-hp. electric machine and other equipment including the washery drives and pumps are being electrified.

NITROSITES AND SILVER DETONATORS—The nitrosites have been patented as initiators of explosion. Little is known of their structure and properties. As amylene nitrosite is stable and representative of the group, it has been chosen by the U. S. Bureau of Mines for a study of its structure and properties. The method of its preparation was studied, its structure determined, and a method developed that gave a yield of about 50 per cent theoretical.

In connection with the general study intended to develop new uses for silver, research work on detonating silver compounds has been undertaken. The silver salts that are considered to have explosive properties have been made and tested. Their sensitiveness to heat and impact and explosive strength were determined. Experimental work has been conducted with silver azide, silver fulminate, the silver salts of some of the nitroaromatic compounds and silver oxalate. Work has been completed on silver acetylide and the silver salt of trinitrohydroxyaminobenzene. Other silver compounds were tested but did not have any of the essential properties of an explosive.

OXYGEN OIL EXPLOSIONS—An investigation intended to determine the conditions under which compressed air or oxygen in contact with hydrocarbon and other oils may be subject to explosion hazards, and to devise means of safeguarding against such hazards, is being conducted at the Pittsburgh, Pa., experiment station of the U. S. Bureau of Mines. Since the publication of previous results, the explosibility temperatures for eleven additional substances have been determined in the 4-cc. test bomb using high-pressure oxygen. A number of experiments was also made using low-pressure oxygen, high-pressure air, and a mixture of oxygen and helium.

**In the Hazard Field**

This school building and mine of the Sapphire Coal Co. are located on First Creek in the Hazard Field of Kentucky. Formerly the First Creek Mining Co. under the management of Jewett, Bigelow & Brook, it is now operated by the Blue Diamond Coal Co. of which W. H. Sienknecht recently was made general manager.

# Labor History of Appalachian Coal Region Records Unionism's Utter Failure

By Sydney A. Hale
Special Contributor, *Coal Age*,
New York City

THERE is a striking parallelism in the history of union activities in the four states discussed in this article. In each case organized labor gained a foothold in its salad days and in some instances it was able to maintain that foothold for several years. But in each case the United Mine Workers was dislodged and, after a period of guerilla tactics, ceased to be a factor. The World War revived the hopes of the labor leaders and made the operators less determined in their resistance to the union program. The United Mine Workers made gains, tremendous gains in those days. But not a single victory was permanent. In these four states, as elsewhere, there has been a challenge to union leadership which has not been met.

THE POSITION the United Mine Workers holds today in the great Appalachian Region is the weakest since organized labor began to exercise a national influence in bituminous coal mining. In northern West Virginia, the last strongholds of the Lewis organization in that state are tottering: the southern fields have been swept completely beyond the control of Indianapolis. The dubious lease of power in the Upper Potomac-Georges Creek area has been broken. The skeleton organization maintained by the United Mine Workers in eastern Kentucky and Tennessee is now only a shadow which frightens nobody with pretensions of authority. Alabama, drawn back into the union ranks during the World War, again proclaims its ability to conduct its affairs without the advice or assistance of the international body of mine workers.

Central Pennsylvania, for years a fertile field for union propaganda, has, with the exception of a few operators, abandoned the labor organization headed by John L. Lewis. Strong union counties in that coal field have followed Somerset into the non-union fold. As was related in an earlier article in this series, the banner of revolt has been raised in southern Ohio and in western Pennsylvania. In the more northerly Butler-Mercer sector of the territory of District No. 5 of the United Mine Workers the union is no longer recognized as supreme. Only in the Broad Top and Blossburg districts has the United Mine Workers been able to retain a tight grip.

### UNION MAKES NO GAINS

To this catalog of losses there are no offsetting gains to be chalked up for the union. Westmoreland County, aggressively non-union for many years, still remains hostile to organized laobr. The Connellsville district, in which Mr. Lewis' organization gave an unexpected demonstration of power in the general strike of 1922, has been restive in recent months as a result of agitation for increased wages by the independent operators, and there have been some labor disturbances, but no general movement to demand union affiliation or recognition. The Windber sector, another quarter in which the union had a brief success three years ago, is quiet. The action of the largest operator in that section in reducing wages several months ago provoked no unpheavals, notwithstanding the fact that this particular producer had normally maintained its rates on levels as high as those prevailing in the union fields. Despite rumors some time ago that the union would make a renewed drive on southern West Virginia, the surface of labor relations there is unruffled.

The measure of disintegration which has taken place can best be understood when it is remembered that at one time or another the power of the United Mine Workers—or one of its predecessors in interest—has been felt in every state and in every district in the Appalachian Region. The process, as succeeding paragraphs will disclose, has not been uniform. Neither has it been constant. In some cases the tide of union power has ebbed and flowed. The union has staged some striking "come-backs" in fields where it was generally believed that its influence had been irretrievably shattered. In certain other sections, influence painfully and gradually built up over a long period of years has vanished almost over night. The most significant development since the close of the World War, however, has been the acceleration in the rate of disintegration.

### DISINTEGRATION SHARPLY ACCELERATED

The rapidity with which the tide has set in against unionism in the great coal belt extending from Pennsylvania through Ohio, Maryland, the Virginias, eastern Kentucky and Tennessee to Alabama threatens to blot out, in the popular mind, recollection of just how powerful the United Mine Workers has been in this region in days gone by.

Vigorous efforts to organize Alabama were made early in the history of the United Mine Workers, but the captive mines of the steel companies proved a stumbling block in the path of the union. Those mines in 1904 upset an arbitration award of the preceding year, claiming the scale fixed too high—and then offered concessions to avoid a strike. These concessions were rejected. A bitter struggle ensued, terminating in the disruption of the joint agreement which had been negotiated between the union and the commercial mines and the collapse of the union organization in that state in September, 1908. From that time until 1917 the right of the Alabama operators to run their mines on an open-shop basis was uncontested. Union membership dwin-

---

Sixth of a series of articles describing the changes in the labor status of the different bituminous coal producing districts of the United States in recent years. Preceding articles appeared in *Coal Age*, Sept. 25, Oct. 1, 8, 29 and Nov. 19. Another article will appear in an early issue.

dled from a peak of 10,668 in December, 1902, to a nominal figure.

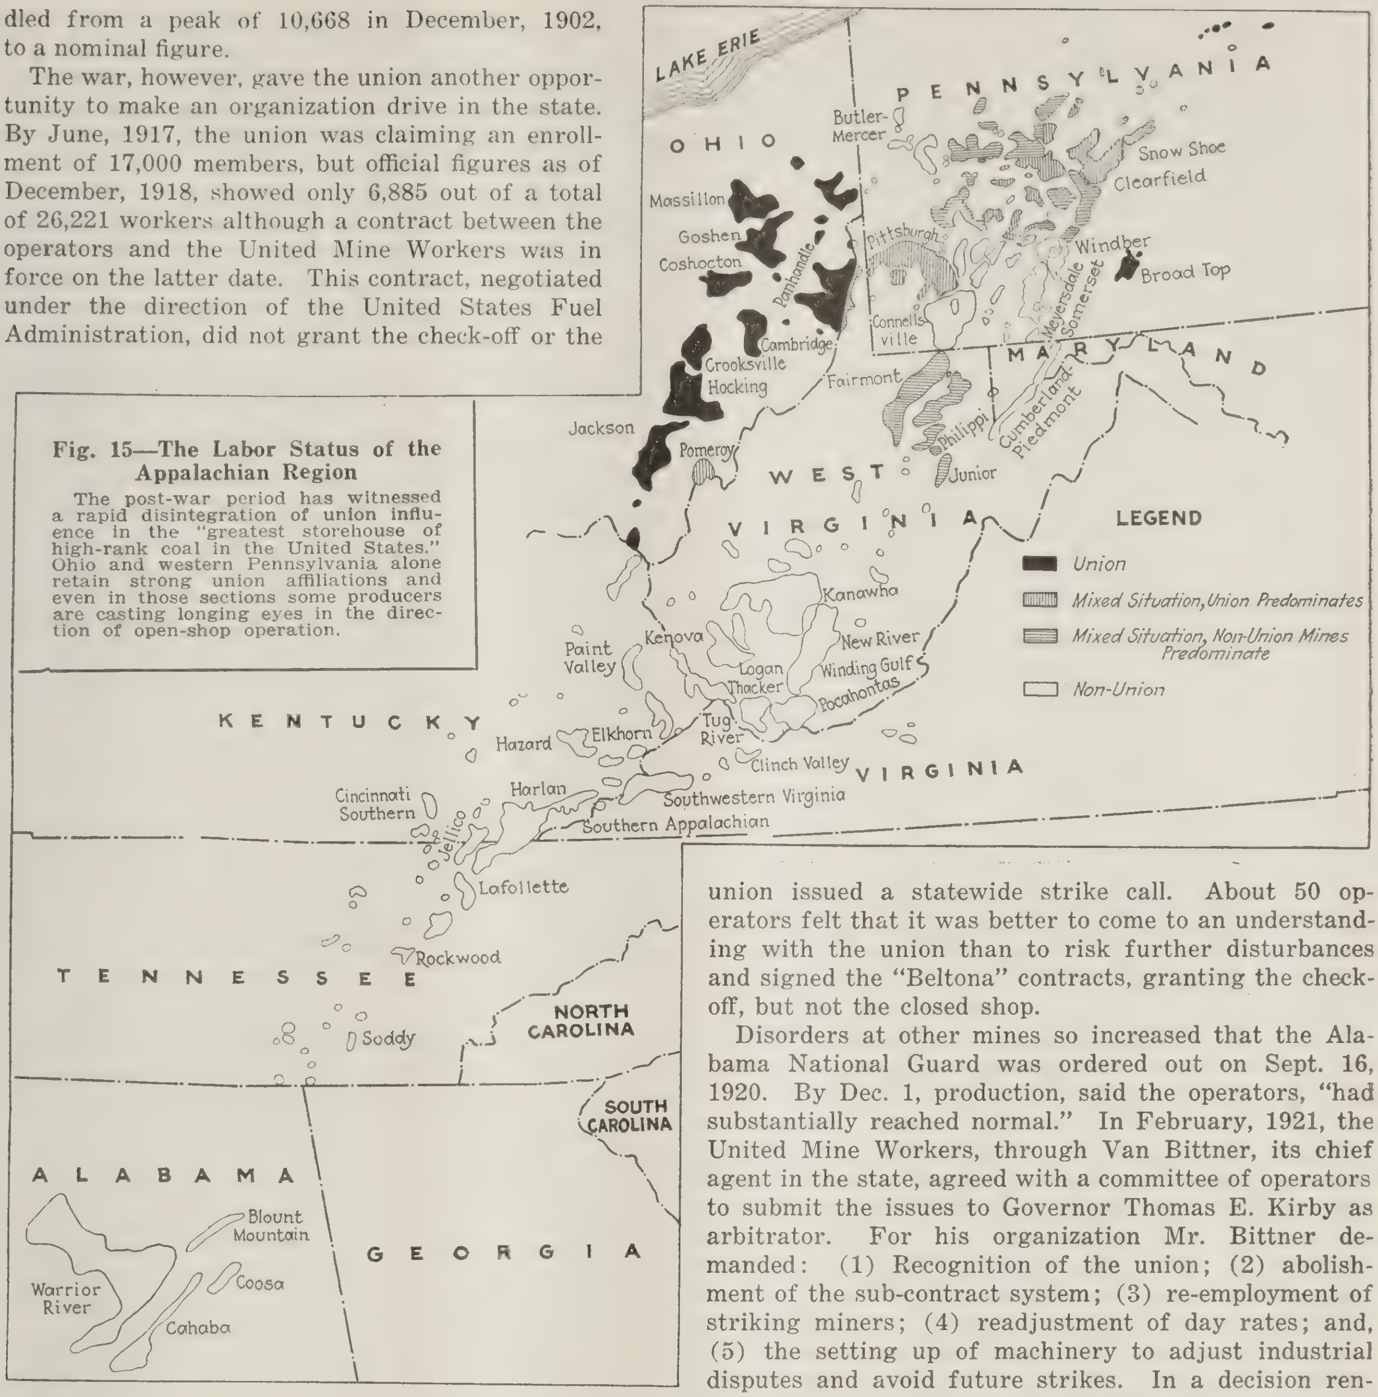

**Fig. 15—The Labor Status of the Appalachian Region**

The post-war period has witnessed a rapid disintegration of union influence in the "greatest storehouse of high-rank coal in the United States." Ohio and western Pennsylvania alone retain strong union affiliations and even in those sections some producers are casting longing eyes in the direction of open-shop operation.

The war, however, gave the union another opportunity to make an organization drive in the state. By June, 1917, the union was claiming an enrollment of 17,000 members, but official figures as of December, 1918, showed only 6,885 out of a total of 26,221 workers although a contract between the operators and the United Mine Workers was in force on the latter date. This contract, negotiated under the direction of the United States Fuel Administration, did not grant the check-off or the closed shop. It "was by its terms to continue until April 1, 1920." Nevertheless, the union called out its Alabama miners in the general strike of 1919.

With the expiration of the "Garfield agreement" in 1920, the United Mine Workers renewed its campaign for greater recognition. Several operators did acquiesce in demands for fuller recognition—but without the check-off—and agreed to the so-called "Blue Book" contracts. A number of other producers agreed to the scale of wages fixed by the award of the United States Bituminous Coal Commission and to an extension of the general provisions of the Garfield agreement. These contracts, signed with the individual employers, whose action had the approval of the union, were known as "White Book" or "Ruby" contracts.

Local strikes in May, 1920, induced about 30 producers who had been operating under Ruby contracts to sign the Blue Book agreements. Unsettled labor relations marked the midsummer and on Sept. 7 the union issued a statewide strike call. About 50 operators felt that it was better to come to an understanding with the union than to risk further disturbances and signed the "Beltona" contracts, granting the check-off, but not the closed shop.

Disorders at other mines so increased that the Alabama National Guard was ordered out on Sept. 16, 1920. By Dec. 1, production, said the operators, "had substantially reached normal." In February, 1921, the United Mine Workers, through Van Bittner, its chief agent in the state, agreed with a committee of operators to submit the issues to Governor Thomas E. Kirby as arbitrator. For his organization Mr. Bittner demanded: (1) Recognition of the union; (2) abolishment of the sub-contract system; (3) re-employment of striking miners; (4) readjustment of day rates; and, (5) the setting up of machinery to adjust industrial disputes and avoid future strikes. In a decision rendered March 19, 1921, in which he found that the miners had no grievances as to living conditions, working hours and wages, the Governor rejected all the Bittner demands. Since that time the union has been without standing in the state. In the general strike of 1922, the Alabama mines worked steadily.

### UNION VS. NON-UNION TONNAGE RATES

Base pick-mining rates in the Central Competitive Field increased 47c. per ton between April 1, 1912, and Jan. 1, 1923. During the same period base rates in Alabama increased 20 to 37c. per ton. The Alabama record in detail is shown in Table VIII.

The union has had a checkered career in eastern Kentucky and Tennessee. The first organization drive in the last named state was made about the same time that the union launched its membership campaign in Alabama. The first test of strength was made in 1904-5 when the furnace operators of the state, like the captive mines in Alabama, refused to be bound to the union. Notwithstanding this defection, a large majority of the operators in Tennessee and adjacent Kentucky fields continued to work under union agreements and granted the check-off. This relationship was not seriously disturbed until March 31, 1910, when the leading commercial producers declared that wildcat strikes and other conditions winked at or imposed by the United Mine Workers had grown so intolerable that they could no longer recognize the union. In this position they were supported by all but a few small companies.

### War Revives Union Drive

In 1917 union organizers again became active and succeeded in enrolling the majority of the workers as members of the United Mine Workers. A strike to compel recognition followed. The United States Fuel Administrator intervened, demanded an immediate resumption of operations and the consummation of an agreement. This agreement, known as the Washington agreement, denied the closed shop and set up an arbitration board with a permanent referee to pass on disputes arising under the contract. According to the operators, however, the same conditions which had led to the breach of 1910 developed, culminating in the general strike of 1919. In spite of the inclusion of District No. 19 in that strike order, when the Washington agreement expired in March, 1920, the operators accepted another one along the same general lines. This was known as the Knoxville agreement and expired March 31, 1922. At that time the Southern Appalachian Coal Operators' Association, which had represented the employing interests parties to these agreements, declined to have further dealings with union labor. The decision, however, was not unanimously approved. As a result of the split the Kentucky-Tennessee Operators' Association was formed to take in the deserting members and non-members of the older organization in the southeastern district of eastern Kentucky and in Tennessee.[1] The junior organization entered into an open-shop agreement with the miners. This contract denied the check-off and carried a provision for readjustments in wages to meet competitive conditions. This agreement, with a downward readjustment, was renewed for a four-year term beginning April 1, 1924. Although signed by district officials of the United Mine Workers, the character of the contract is such that the operating districts covered by it cannot be classed as union territory.

### Open-Shop Policy Abandoned

Northeastern Kentucky has been non-union since the field was developed. Two companies in that field—the Consolidation Coal Co. and the North East Coal Co.—ran open-shop for a number of years and made no effort to discourage union membership. These companies now refuse to employ members of the United Mine Workers, basing their refusal on the attempt to close their operations in the general strike of 1922 and the violence with which that attempt was made.

The fact that many of the companies operating in the Appalachian Region deal directly with their men makes the publication of complete rate sheets impossible.

**Table VIII—Alabama Basic Wage Rates (in Cents)**

| | Mining Rate* Per Ton | Hours Worked | Day Labor Rates per Hour — Inside Labor — Motormen | Trackmen | Outside Labor — Tipple Foremen | Common Labor |
|---|---|---|---|---|---|---|
| Dec. 1, 1914 | 52.0 | 10 | 20.0 | 27.0 | 18.0 | 14.4 |

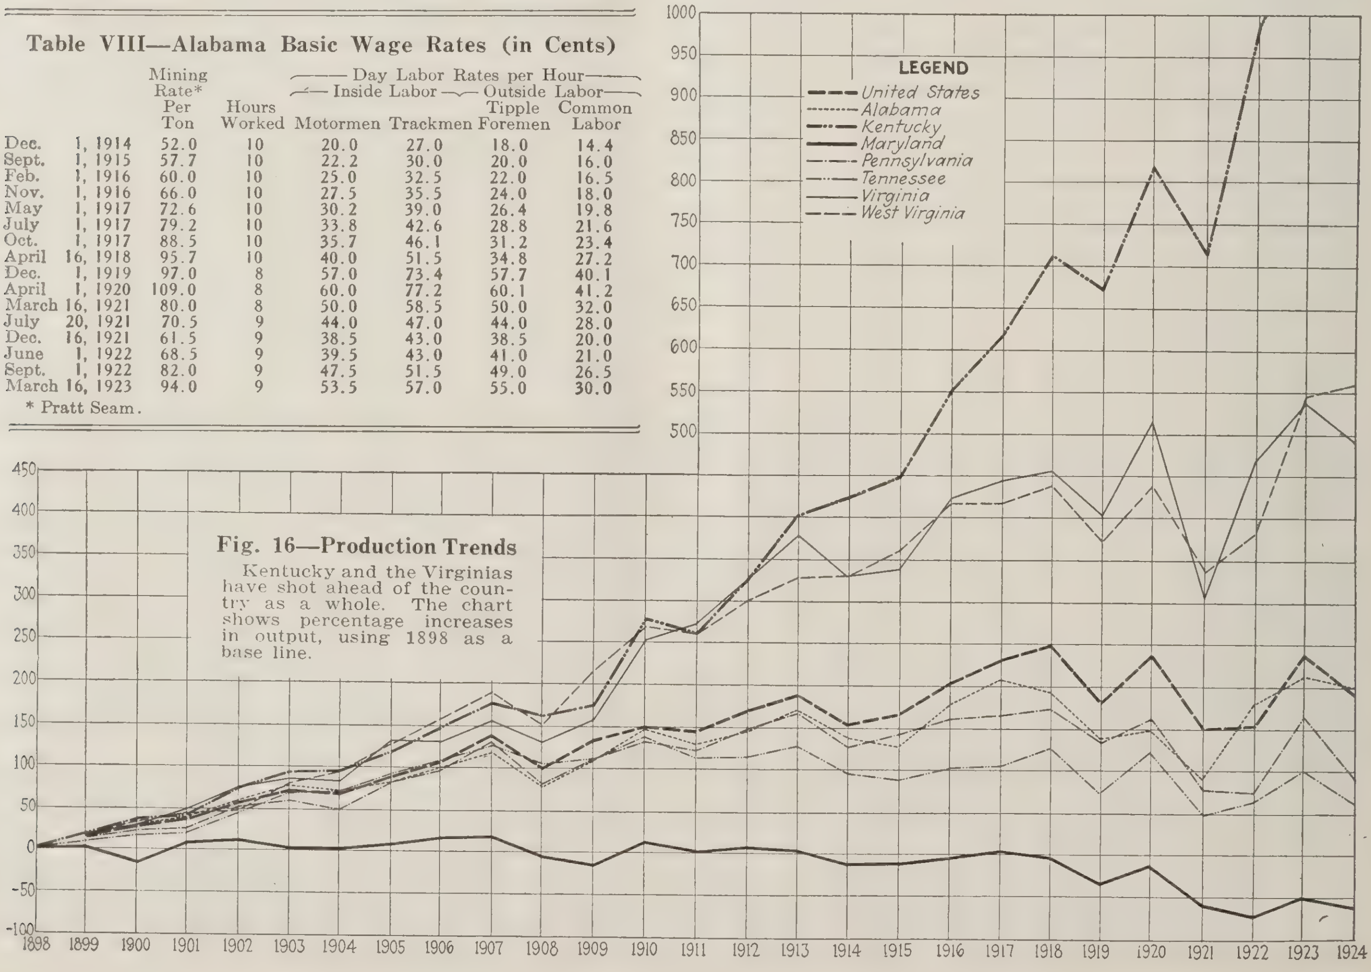

**Fig. 16—Production Trends**

Kentucky and the Virginias have shot ahead of the country as a whole. The chart shows percentage increases in output, using 1898 as a base line.

---

[1] The Southern Appalachian Coal Operators' Association covers operations in Bell, Knox, McCreary, Whitley, Clay and Laurel counties, Kentucky, and in Tennessee. Approximately 80 mines with a maximum capacity of 7,000,000 tons per annum and an actual output of nearly 5,000,000 tons in 1924 are members. The Kentucky-Tennessee Operators' Association at the time of its organization reported a membership of approximately 3,000,000 tons per annum.

Table IX, however, gives a history of typical changes in pick-mining rates in the Appalachian Region and, for comparative purposes, also shows the base rate in the Central Competitive Field. The most pronounced changes, it will be noticed, began during the war period. In some cases non-union rates during the war and the post-strike boom months exceeded Central Competitive Field base rates. On the other hand, rates during periods of depression more nearly reflect actual conditions in the open-shop districts than is the case in the strong union fields. The non-union rates quoted in Table IX are, it should be emphasized, typical rather than complete. Many operations in the same fields paid lower than the rates named: in a few instances, higher rates were paid.

### UNION HAD EARLY START IN MARYLAND

The Maryland coal field first felt the influence of unionism in 1881 when the old Knights of Labor invaded the Georges Creek and Upper Potomac districts and gained enough recruits to cause a strike in 1882 which lasted nearly six months. The walk-out was a protest against a reduction of 15c. per ton in the mining rate and was unsuccessful. Two increases after the men had returned to work, however, restored the basis for which the men had struck. A cut of 10c. late in 1884 was followed by a strike in March, 1886: this lasted six weeks and ended in the defeat of the men. Twelve years passed before organized labor again became active: in 1898 and 1899, the United Mine Workers launched a membership campaign in Maryland and on April 1, 1900, ordered a general strike for an advance of 10c. per ton more than the operators already had announced. The strike was broken after four months and the union retired from the field.

Open-shop conditions without a suggestion of union recognition prevailed until the World War period. Organization work was renewed early in 1917 and a two-day strike staged in April, 1918. Out of this grew a joint agreement between the operators and district and local officials of the United Mine Workers acting "in behalf of the mine workers." With the general strike of November, 1919, this agreement was thrown into the discard. No action looking toward a resumption of contractural relations was taken until nearly a year later, when a committee of employees requested a joint conference. The principle of collective bargaining was again recognized in an agreement to expire March 31, 1922, but there was no direct recognition of the union as such.

## Table X—Pick-Mining Rates in Maryland

(In Cents per Gross Ton)

| Sept. 7, 1882 | 40.0 | April 1, 1920 | 131.5 |

* Exact dates not available.

At the insistence of union representatives, however, a provision calling for a joint meeting in January, 1922, to continue the contract was incorporated in the agreement. Meetings were accordingly held in January and adjourned, at the miners' request, until after the convention of the international union at Indianapolis. Late in March, 1922, the operators demanded another conference or an agreement to continue work under the expiring contract. Despite this demand, a strike was called on April 1 and the representatives of the miners stated that "they would have to defer the conference until matters at issue in the Central Competitive Field were settled." Some months later (August 18, 1922) the operators notified the employees' representatives that they (the operators) deemed the action of the employees' representatives a violation of the basic agreement of Dec. 11, 1920 and "that they considered the agreement terminated."

### MARYLAND SHAKES OFF UNION

The attempt of the majority of the Maryland mines to operate open-shop after April 1, 1922, was met with a counter-campaign of intimidation and violence which ran throughout the greater part of 1923. This warfare was waged by union sympathizers notwithstanding the willingness of the producers to pay wages in line with the levels fixed in the 1920 agreement. The international organization, which during this long conflict had been able to induce only a few small mines to sign up, finally acknowledged defeat in an order calling off the strike on Nov. 23, 1923. Nearly $750,000 had been poured into the state by Indianapolis in the futile effort to force recognition.

At the time the United Mine Workers was beaten in 1900, the basic pick-mining rate in Maryland was 55c. per gross ton. During the period (1900-1919) in which the state was free from union dominition, the rate advanced to $1.194 with proportionate increases in day rates. The history of pick-mining rates in the state since Jan. 1, 1855, is shown in Table X.

# Center Shearing Increases Percentage of Lump

By N. D. Levin*
Columbus, Ohio

What would an appreciable increase in the amount of lump obtained in mining mean to the coal producer? To some the percentage of lump makes no difference; to others a goodly yield of large sizes is of the utmost importance, spelling all the difference between a profit and a loss. Ways and means for increasing the proportion of lump coal are most interesting to those to whom large sizes are important, but the same methods help those operators who have other adverse conditions such as weak roof with which to contend. Inasmuch as less explosives are employed, the roof is subjected to less violent jarring, and a smaller quantity of timbering is required.

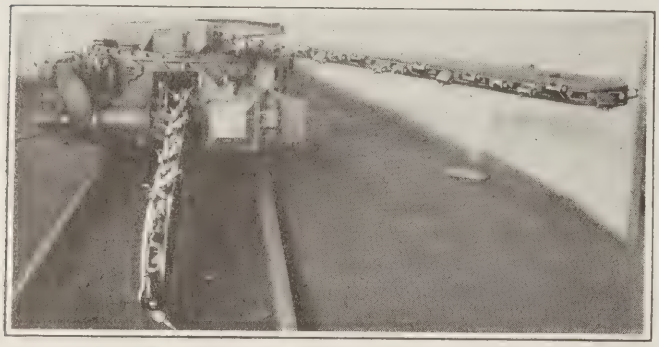

**Fig. 1—Combined Shearing and Center Cutter**

This machine both center cuts the face and shears it at the same time. The shearing cutter gets out of the way of the swinging bar by the time it reaches the center of the room. The shearing bar can also be attached to a machine arranged for undercutting the face.

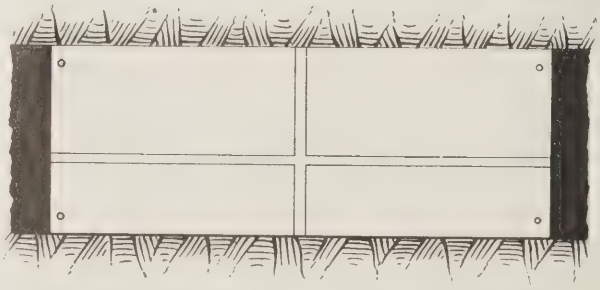

**Fig. 2—A Face Center Cut and Center Sheared**

This drawing also shows the locations of the four shotholes necessary to bring down the coal. Machines already are available for undercutting and shearing the face as well as for topcutting and shearing it. In any case a loose end of coal is made available.

As every mining man knows, a shear cut in a coal face makes a "loose end," that is, it exposes an additional face of coal to the air and renders it much easier to shoot. Such a shearing cut may be made either simultaneously with the undercut or center cut, or it may be put in either before or after the horizontal cut has been made.

In the accompanying illustrations, Fig. 1 shows a combination machine adapted to making both of these cuts simultaneously. In use, both cutterbars are sumped at the same time. When the machine has been brought up to the face the vertical bar starts its downward sweep at the same time that the horizontal bar starts its swing. The shearing bar is out of the way by the time the swinging bar reaches center. Fig. 2 shows the face of a room cut in this manner. A somewhat similar treatment of the face, preferred in many localities, is shown in Fig. 4. Here the horizontal cut is made at the bottom of the coal instead of in its center.

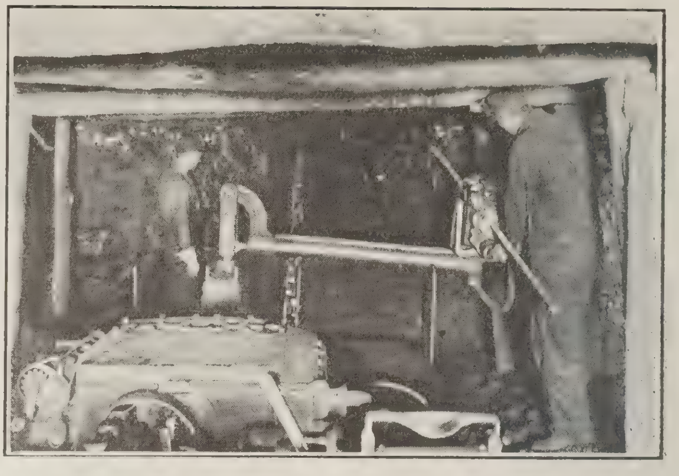

**Fig. 3—Power Drilling the Shotholes**

A counterpoised power drill may be mounted readily on the cutting machine in such manner that the machine runner can drill one shothole and the helper the other during the time that the two cuts are being made in the face.

Naturally, undercutting and shearing may be performed separately, a machine being used for each of these operations. An electric drill may be mounted readily on a shearing machine so that the shot holes may be power drilled while the shearing cut is being put in. Only two holes are required in a center-sheared face and the quantity of explosive employed is appreciably reduced because of the loose ends resulting from the shearing cut. Less powder means less jarring of the roof which in turn means that fewer or smaller timbers will be needed for its support.

Snubbing the face is also an efficient means of increasing the percentage of lump coal. Various machines and methods are available for this purpose. It is questionable, however, if this will yield results comparable with center shearing. Machine loading puts bigger lumps onto the cars than hand loading because pieces

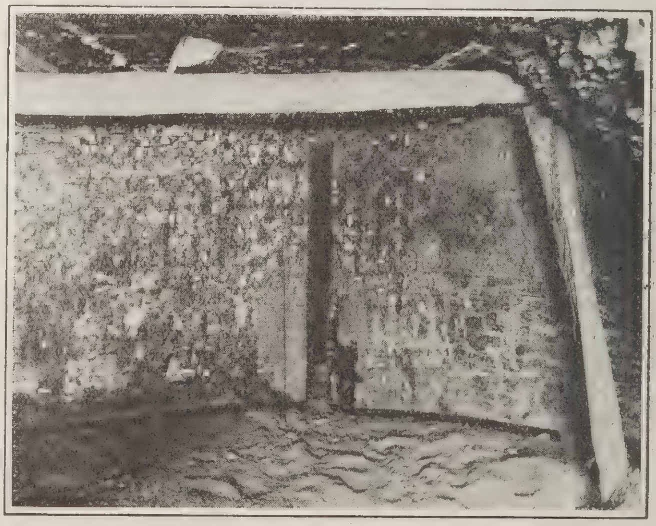

**Fig. 4—A Face Undercut and Sheared**

The two shotholes may be seen upon either side of the shear cut approximately above the sides or extremities of the undercut. This face is now ready for loading and shooting. The shear cut takes the place of the center drill hole and because of the loose ends only light charges of explosives are needed in the side holes. Thus the roof is subjected to light jarring only.

---

*Chief engineer, mining department, Jeffrey Mfg. Co.

can be gathered onto the machine conveyor so big that they could not be lifted aboard a car by hand.

There is small question but what center shearing of the coal face in the future will receive far greater attention on the part of coal operators than it has in the past. This will be particularly true in those localities where conditions are highly competitive and a domestic grade of bituminous coal is produced. Some of the largest operators in southern Illinois have for months been experimenting with shearing machines with highly promising results. Its other advantages, however, in addition to the greater production of lump coal made possible, (such as decreased use of explosive and timber, and less jarring of the roof) will render it highly attractive to operators in other coal regions.

## Union Pacific Grinds Its Own Shale Dust

To provide a suitable rock dust for use in its mines the Union Pacific Coal Co. has erected at Mine No. 7, Rock Springs, Wyo., a shale dust plant, the site chosen being a short distance from the power plant. As the mine does not afford good material and as the crop reveals little but sandstone, it has been necessary to bring the material for pulverizing a long distance, in fact eight miles. A white shale is found in White Mountain (which, indeed, takes its name from the prevalence of the rock) and it is of excellent quality as Table I, provided by the U. S. Bureau of Mines, will show.

The plant, which was supplied by the Williams Patent Crusher & Pulverizer Co., has a capacity of over seven tons per 8-hr. day. The dust is sacked at the mill and distributed to the various mines. At present the rock is hauled by motor truck at a cost of $2.60 per ton. The hope is that the whole labor and material cost of obtaining and manufacturing the dust can be brought to $4 per ton as soon as the rock is transported by railroad from the Green River region where an identical rock is to be found. The Union Pacific Coal Co. is furnishing the dust to commercial mines in the vicinity which have not yet made provision for meeting the safety needs of their mine by plants of this kind. The shale is put in sacks holding 70 lb. The cost of operation of the plant is shown in Table II. The pulverizing and sacking are done alternately and two men are employed in both operations.

**Table I—White Mountain Shale of Union Pacific Coal Co.**

| | As Received | Moisture Fre |
|---|---|---|
| Moisture at 105 deg. C. | 2.0 | .... |
| Ash | 82.8 | 84.5 |
| Carbon dioxide | 11.0 | 11.2 |
| Combined water (above 105 deg. C) | 3.5 | 3.6 |
| Total incombustible | 99.3 | 99.3 |
| Combustible (by difference) | 0.7 | 0.7 |
| Free silica or quartz $SiO_2$ estimated | | 8 per cent |
| *Size test* | | Cumulative per cent |
| Through 20-mesh | | 100.0 |
| Through 200-mesh | | 88.2 |

MICROSCOPIC EXAMINATION

This dust is of a yellowish cast, yet light in shade, microscopically there appears to be but little free silica or quartz ($SiO_2$), probably less than 5 per cent. There is from 10 to 15 per cent of calcite ($CaCo_3$) in the sample. The rest is largely kaolin or other clay minerals with a few micas, etc.

**Dust Mill Protects Wyoming Mines**

The Union Pacific Coal Co. at Rock Springs, Wyo., pulverizes its own rock dust from shale obtained from a deposit in White Mountain. It has a low free silica content and is ground so that nearly 90 per cent goes through a 200-mesh screen. The dust is light enough to aid considerably in illuminating the headings.

**An Up-to-Date Mining Community Fostered by the Consolidation Coal Co.**

This is the mining town of Dunham, located near Jenkins, Ky., which with Burdine forms the group of model mining communities where the Consolidation Coal Co. produces 1,200,000 tons of coal per year. At Dunham the miners and their families do not live in hovels common to many coal towns, but here they have modern, well-kept homes and many have their own gardens. The "town square" exemplifies the cleanliness that prevails throughout the community.

# Minto Region Mining Is Both Primitive and Modern

### This New Brunswick Field Has Hand-Power Haulage of Tiny Cars on Wooden Rails in One Section and Electric Cutters in Another

By John McNeill
North Minto, New Brunswick

Extensive and complicated timbering and a potpourri of primitive and modern coal mining methods and equipment ranging from electric cutters back to hand-power haulage of tiny cars with wheels like those of a baby carriage are to be seen in the little-advertised Minto region of New Brunswick, Can. The district is in Sudbury and Kings counties. It is the only coal field in operation in the province, and so far as is known contains the only coal bed in New Brunswick, with the exception of an extremely thin measure at a place called Barryville.

In thickness the coal throughout the Minto field does not average more than 28 in. but it has been worked in places scattered over a distance of about 6 miles north and south. The breadth of the operated area is not more than a mile but the total extent of the field has not been determined.

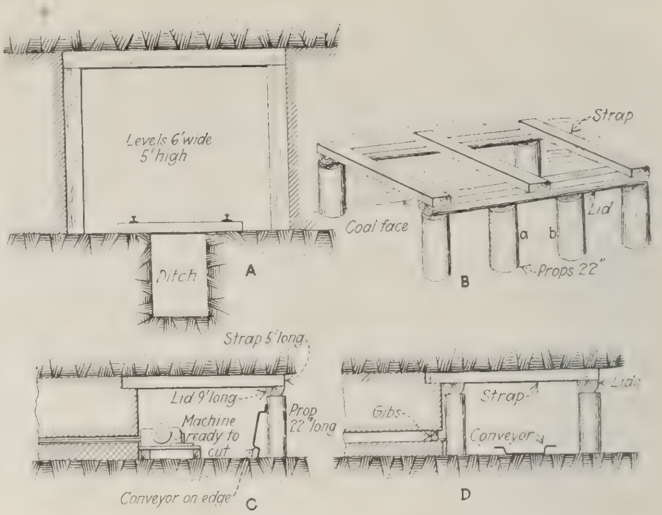
This coal field deserves consideration because of the difficulty encountered in working it in competition with richer fields. The roof is bad and the coal thin and hard. The field also is troubled seriously with water. It thus possesses most of the disadvantages encountered in mining and to operate in it requires as careful study as fields where the output from a single shaft reaches 10,000 tons a day.

As a whole this district is divided into two sections known respectively as South Minto and North Minto. The southern section has been longer in operation. Here the coal crops out and in the past has been won by strip mining. The output was not large, however, for in many places as much as 20 ft. of earth had to be removed to expose 20 in. of coal.

Most of the coal throughout this region is now reached by shafting. All over the field there are many small shafts from 50 to 100 ft. deep. The system of mining is board and pillar. The boards are 15 ft. wide and the pillars are of equal width. It is unusual to see a thin bed of coal worked by board-and-pillar. Some day a longwall system may be tried by hand mining. The main difficulty will be that of keeping the road roof and sides from crushing and blocking the entrances.

Minto Power Plant Supplies the Mine and Town

This plant generates the current necessary for the operation of the mining machines underground, the pumps employed in mine drainage and for lighting the town and vicinity of Minto. Its capacity is about to be substantially increased in order to meet the requirements of the steadily growing load.



Details of Drainage and Timbering

Water is extremely troublesome in these mines. Ditches for its removal are dug in the center of the tracks on all headings and by headings as shown in *A*. The machine faces are timbered by posts upon which rest lids or booms extending parallel with the face. Across these and supporting the roof, straps or beams are placed which are hitched into the face at their opposite ends. As the face is undercut additional posts and booms are set under the forward ends of these straps, thus relieving the face of all roof pressure. In *B* the props *a* and *b* are thick and are called "breakers." They are set before the machine cuts because the roof is troublesome.

In South Minto the roof is so soft that the coal is mined, or "stripped" as it is called, by hand picks. During this process, however, the roof has to be supported by short boards driven over a running boom from behind. The boards, called "laths," are 4 ft. in length, 6 in. or more in width and 1 in. thick. The running boom or "lid" is, of course, completely covered with laths, so that when the coal is extracted, a roof of wood remains all over the place. If care is not taken in placing the laths the roof may run down until it chokes itself. It will be seen that the skill of a builder as well as that of a miner is here required.

In these mines the cars hold only 5 cwt., or 560 lb. of coal each. They run on wooden boards 6 in. wide nailed to the ties. The wheels of the cars are like those of a baby carriage, but they run all right when the wheeler becomes accustomed to keeping them on the boards. The art of mining is developed in South Minto to as high a pitch as in "aristocratic" mines. Men work there who have mined coal in all parts of the earth, and they buy "moonshine" and motor cars, and swear, and go to church, and have dances—"even as you and I."

North Minto is different. Two companies are in operation there employing some 500 men. The shafts are about 100 ft. deep and the bed of coal is 2 ft. 2 in. thick but carries a 4-in. parting of "mud," as it is called locally. This mud is in reality a hard rock, and rests on 5 in. of bottom coal. The total height of the working is thus from 2 ft. 6 in. to 2 ft. 8 in. In this locality the roof is shale, easy to break, full of slips and joints which run in all directions and contains "pots," which if not carefully watched are sure to fall out. In such places the rock arrangement appears to be such that if one piece falls out, a bigger one will follow.

The following timbers are used for roof support: "Lids" or split booms 6 ft. long used to protect roadway roofs; "straps," planks 6 ft. long 2 in. thick and 6 in. wide, used along the face; "laths," boards 4 ft. long 6 in. or more wide and 1 in. thick used in whatever way may be required, and props of various lengths from 20 in. to 6 ft. A timberman is kept busy on the bankhead cutting timber and sending it into the mine.

In this locality also the bed is worked on the board-and-pillar system. The coal is so hard it cannot be dug with a hand pick and, accordingly, is shot from the solid. Naturally, in a thin bed such as this the results are not good. Even in the thinnest pillar, explosives must be used to bring the coal down. It never crushes as it does in some thin beds, and even a small nose is hard to cut.

Water constitutes a big obstacle to mining operations. The seam has hardly any distinct inclination, and no matter in what direction a place is driven, a small hollow is liable to be encountered which always fills up with water. And water in a low bed is a great drawback. To cope with it, ditches are dug on all the main levels, by-levels, and sometimes in the rooms. In some instances, also the bottom coal and mud are left in place and only the top coal worked.

### BOYS AND MEN PUSH CARS

The ditches dug for drainage purposes are from 1 ft. to 3 ft. deep and are located in the middle of the roads. The ties are laid across them and boards are nailed to the ties so that a good road to walk on is provided. Of course no horses are employed in these mines. So far the cars have been pushed to and from the bottom of the shaft by boys and men. These cars hold 10 cwt., or 1,120 lb. of coal each.

The volume of water, encountered in these mines is not large but the way in which it spreads in the low workings makes it troublesome. Most of it is drained through the ditches, to a single-stage centrifugal pump, that delivers it to a surface stream. A 4-in. pipe is large enough to keep the water down. Open lights are used in all the mines of the region as inflammable gas has never been detected there.

A year ago one of the operating companies introduced coal cutting machines. These are of the chain type and at the present time four are in use, cutting being done in the so-called "mud," and on a long face. These machines have all they can do to cut at all, but as a rule they undermine from 200 to 250 ft. of face in one shift.

**Miner's Dwelling at Minto**

Minto has its housing problems as well as other mining communities. This illustration shows the type of houses that have been erected for the use of the miners. There is nothing fancy in the architecture or construction of this cottage, but it is, nevertheless, neat, comfortable and "homey."

The coal is shoveled from the floor into conveyors and by them moved along the face of the run to the car. As the roof is heavy and slippery it has to be supported in a perfectly systematic manner. A running boom or lid is set on 2-ft. props which hold it from 2 to 3 in. below the roof. The props are kept 4½ ft. back from the face of the coal to let the machine pass. One end of a strap 5 ft. long is laid on the lid, the other end being hitched on top of the coal. These straps are not over 2 ft. apart. As the machine moves along its cut gummers shovel the cuttings into the gob while timbermen gib or sprag the coal and set a running boom or "lid" under the straps. When the miners shoot the coal they timber as they shoot. Thus they put straps above the last lid set hitching them on top of the new coal face. No mistakes must be made in timbering. With such a roof in a low place frequently troubled with water from both roof and floor, it will be seen that conditions for machine mining are not of the best. So far, however, it has been a success.

The company using the electric undercutters owns an electric plant which furnishes power for the hoists and cutting machines and also lights the town and neighborhood of Minto. Two generators are installed, each capable of yielding 310 hp. at 1,100 volts. Two large boilers furnish steam to these machines and a third unit is now being installed. This will add materially to the capacity of the plant.

**A Modern Mining Town in the Mountains of Kentucky**

This town of Burdine is one of three model communities fostered by the Consolidation Coal Co., in Letcher County, Ky. Built only on one side of the B. & O. R.R. the heart of the village nestles in the valley, and on the picturesque hillside many employees of the coal company have their homes overlooking the little town and affording a bird's-eye view of the valley and the tipple on the opposite mountain side. A modern school building, churches, stores, recreation buildings and a baseball park in this beautiful setting help develop contentment in the lives of the employees of the Consolidation company.

# Union Pacific Coal Co.'s Code of Standards—III*

### Transformers and Transformer Vaults

1. All transformers shall be provided with an oil circuit breaker in the primary circuit, the frame of which shall be effectively grounded.

2. Transformer vaults are to be located between the intake airway and the return.

3. The construction of transformer vaults must conform in plan to Figs. 12-13.

### Wiring of Surface Buildings and Tipples

1. All buildings shall be wired in metal conduits, special attention being given to neatness and the proper support and installation of fittings.

2. The voltage for such work shall be 250 volts or less.

3. Electric heaters in weigh rooms shall be stationary and connected to separate circuits from lighting circuits. They shall be protected with suitable guards to prevent inflammable material from coming within 8 in. of the heating elements.

4. Telephone and signal lines if liable to come in contact with high-voltage power lines shall, at the point where they enter any building, be protected with a Western Electric Co.'s Type 58 A.P. protector or its equivalent installed in a steel box which shall be properly grounded.

5. Motors in dusty places shall be installed in separate rooms which shall be made fire resistant by lining with metal lath coated with cement plaster.

6. Motor wiring shall be installed in metal conduit. Special attention shall be given to guarding exposed conductors and parts that may give electric shock.

7. Motor frames, starting compensators and control equipment shall be effectively grounded.

8. Starting compensators, controllers and switches containing oil, freezing of which will render the apparatus less effective, shall be filled with non-freezing oil.

9. All knife switches shall be of the safety inclosed type.

### Overhead Distributing Lines

An overhead distributing line is taken to mean any circuit or aggregation of circuits on poles, including supporting elements, that are used for supplying electrical energy at a potential not exceeding 2,300 volts. It includes motor, lighting, signal, telephone circuits, etc.

1. Pole spacing shall be 100 ft. in streets and alleys.

2. Pole lines shall be inspected every year to determine condition of butts below the ground line.

3. All lines shall be inspected every two months to determine their general condition.

4. Cross-arms shall have a center-pin spacing of 30 in. and a side-pin spacing of 14½ in.

5. All wires of the same circuit shall be carried on the same cross-arm.

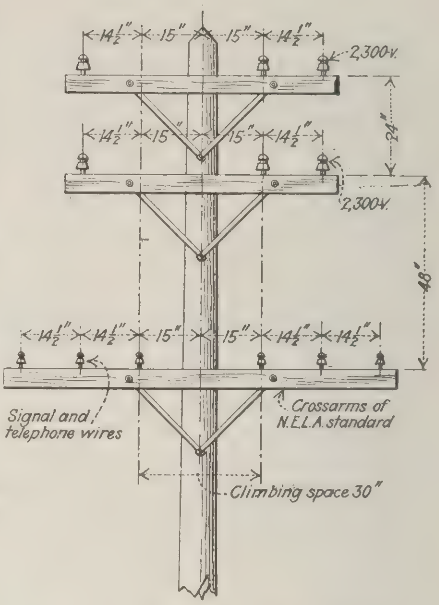


Fig. 14—Making It Safer Among the Wires

Climbing space is provided by setting all wires on the crossarms so that none comes closer than 15 in. to the center line of the pole. Thus a 30-in. clear space is always kept.

6. Vertical risers on poles from underground cables shall have a metallic sheath or be inclosed in a metal conduit.

7. Ground wires attached to the surface of a pole shall be protected by a wooden casing not less than 1½ in. thick and shall not make contact with cross-arm braces, guy fastenings or other exposed metal parts.

8. Guy wires shall have an interlocking strain insulator which shall be so located as to give 6 ft. of horizontal clearance from the pole guyed.

9. All poles to which guys are attached shall be protected with guy shims and guy hooks.

10. For climbing space on poles see Figs. 14 and 15.

11. Cross-arms carrying power wires of the same voltage shall have a vertical spacing of 24 in.

12. Cross-arms carrying signal and telephone wires shall have a vertical spacing not less than 48 in. from power lines.

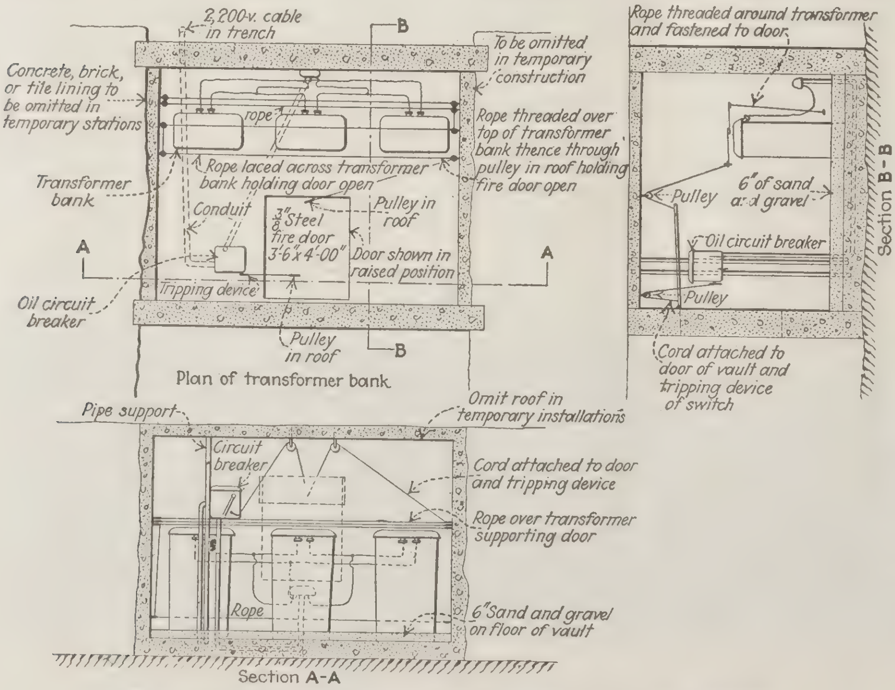
13. Material and minimum size of conductors shall be as follows:

2,300 volt lines, No. 6 B. & S. gage M.H.D. copper; 110/220 volt lines, No. 8 B. & S. gage M.H.D. copper. Signal and telephone lines, No. 12 B.W.G., EB.B. galvanized iron wire. Pole steps shall be ⅝x9 in. galvanized iron.

M.H.D.—Medium hard drawn.
B.W.G.—Birmingham wire gage.
E.B.B.—Extra best best.

### Instructions to Persons Inspecting Electrical Equipment

1. Inspectors shall pay particular attention to ground connections and shall satisfy themselves, beyond doubt, that the ground wire will serve the purpose for which it is intended.



2,200-v. cable in trench

Section A-A

Figs. 12-13—Transformers Are Isolated If a Fire Starts

Besides being inclosed in a vault all transformers used in the mines are set up between the intake and return airways. Rope made of combustible material is threaded around the transformers and normally holds a ventilating door in the vault open. Should a fire occur in the vault the rope will burn and thus permit the door to shut thus confining the blaze and opening the circuit breaker.

---

*This is the third of a series of articles giving the Code of Standards put into effect by the Union Pacific Coal Co., at its operations in Wyoming. The first two articles appeared in the issues of Dec. 10 and 17 and the remainder of the code will be published in future issues in this form that permits of easy filing.

2. Concealed ground wires shall be replaced by others that are visible throughout their entire lengths where possible.

(Note: Parts that should be grounded are: Cable sheaths, conduits, oil switches and operating levers, transformer cases, motor frames, compensator and motor starting apparatus, metal boxes containing switches, resistors or control equipment, secondary circuits from transformers, controllers, pipe frames supporting switch boards and other equipment.)

3. Observe that ground wires from direct-current generators are properly connected to both rails of the track.

4. Wires leading to motors or generators shall be properly guarded.

5. Oil switches and compensators shall be examined for proper oil condition and for accumulations of coal dust.

6. Inspect wires and cables that cross passageways and hoisting slopes, as these may become loose and present a great hazard. Light, telephone or signal wires across slopes may endanger persons on man trips.

7. Determine that overload relays, automatic circuit breakers and under-voltage releases function properly.

8. Synchronous motors are operated with a fixed amount of exciting current at no load. See that the field adustments are correct and that instruments indicate properly.

9. Direct-current generators lose voltage upon becoming warm. See that someone adjusts voltage during the working shift.

10. Familiarize yourself with the operation of all pumps, motor-generator sets and hoists in order to determine that all starting, stopping, controlling and protecting equipment functions properly.

11. Low voltage at any working place or any extra load that is to be added to installed equipment, is to be reported at once to the mine foreman in charge.

Plan

12. Report all equipment overloaded, abused, or poorly ventilated causing overheating.

13. Inspect electrical equipment when not in operation to determine condition of bearings, brushes, commutator and collector rings, and observe condition of revolving parts for air gap clearances loose band wires and dust accumulations.

14. Inspect mining machine cables for bruised places and splices and see that they are adequately insulated and completely protected with rubber and friction tape.

### Safety Standards

1. Smoking or the carrying of any smoking or flame producing materials is prohibited in all mines operated on a closed-light basis.

Sec. 4,439, Wyoming Compiled Statutes.—"Any miner, workman or other person who shall . . . carry any pipe, cigar or cigarette, match or fire-producing material or appliance into places that are worked by safety lamps . . . shall be deemed guilty of a misdemeanor and may be punished in a manner provided in Sec. 4,451 which provides a fine of not less than $200 and not more than $500 at the discretion of the court."

Sec. 4,436, Wyoming, Compiled Statutes.—"Any man working in a mine or mines where safety lamps or electric lamps are used exclusively, shall be subject to search by the mine foreman or his assistants for matches or . . . inflammable materials. No person shall have in his possession in any part of the mine where locked safety lamps are used, any matches or means of producing fire, or any lamp key or instrument for the opening of a locked safety lamp. Any person or corporation violating any of the provisions of this section shall be guilty of a misdemeanor and subject to a fine not to exceed $200."

2. Any miner or other workman who is habitually found working in dangerous places due to his laxity in properly timbering or otherwise making himself safe subjects himself to immediate discharge.

3. All persons entering the mine must be checked in and out of the same, and every person while underground must have his life check on his person and in his right hand front trousers pocket.

4. No machinery of any kind will be allowed to operate unless all gears and other dangerous parts are fully guarded.

5. All mines shall be protected against the propagation of an explosion by rock-dust barriers. These barriers shall conform in plan and general construction and arrangement to Fig. 16.

(NOTE: In places where sufficient clearance is untainable or where it is deemed impractical to support dust barriers by props, they may be suspended from the roof by proper eye bolts. Where barriers are set into the roof, vanes shall be placed on either side of same to deflect the air currents into them.)

6. Dust barriers shall be located on all slopes, air courses, and manways intermediate of all cross entries as shown in Fig. 17.

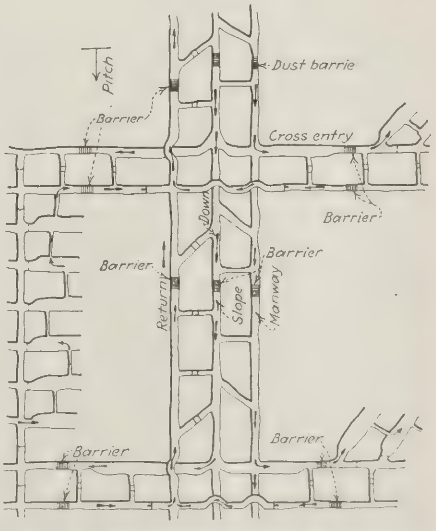

**Fig. 17—Blockades Against Explosions**

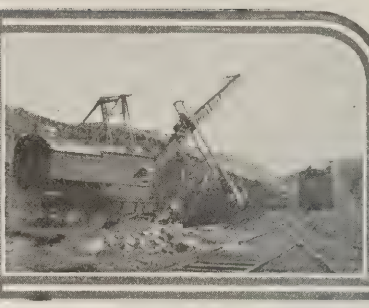
Complete sectionalization is attained by dust barriers on slopes, manways, returns and cross entries, as illustrated. Whatever explosions occur the aim should be to completely isolate them and minimize all danger to adjoining sections.

# News Of the Industry



## Hard-Coal Men Resume Peace Negotiations; Markle Plan Center of Interest

A new plan to insure permanent peace in the anthracite region is now under consideration by operators and miners. The plan, drafted by Alvan Markle, chairman of the joint conference, was submitted to the sub-committee of miners and operators, which resumed negotiations at a meeting which started at the Union League Club, New York, on Tuesday afternoon.

The plan, in full, reads as follows:

"(1) The terms and provisions of the award of the Anthracite Coal Strike Commission and subsequent agreements made in modification thereof, or supplemental thereto, as well as the meetings and decisions of the Board of Conciliation, are to be ratified, confirmed, approved and continued until the first day of September, 1935, subject to renewal every ten years thereafter, except as hereinafter modified.

"(2) The contract and working conditions which were operative on Aug. 31, 1925, are to be extended to and including Aug. 31, 1926.

"(3) Immediately, or as soon as possible, a fact-finding committee, consisting of three miners (or representatives) and three operators (or representatives), shall be appointed by the respective parties.

### Public to Be Represented

"(4-A) The committee shall join in respectfully asking the President of the United States to appoint three impartial citizens, preferably one a mining engineer and geologist, familiar with mining conditions and coal production, but not in any way associated with anthracite coal mining properties, one an economist of established reputation, who has not been employed heretofore by either party, and one a Judge of the United States federal courts. These three men, appointed by the President, are to represent the public, and they are to select a reputable firm of certified public accountants, with authority to investigate and report promptly to the public representatives on every phase of the industry. The three public representatives shall meet with the committee, hear all arguments and facts as presented by both parties, as well as to consider the report of the certified public accountants. They (the public representatives) shall meet separately, prepare a report and submit their recommendations to the President of the United States and joint committee of miners and operators.

"(B) The committee then shall meet as a whole to reach an agreement as to wages and any change in the contract requested by either party, it being understood that the public representatives may enter into all discussions but shall not have a vote except in the following instance:

"If, after the submission of the report of the public representatives named by the President, the miners and operators shall fail to reach an agreement upon any disputed point or points within sixty days after such submission, then in such event the public representatives shall each be entitled to cast a vote upon such disputed question or questions, with the representatives of miners and operators, and a majority of the nine members shall decide the same.

### Committee to Meet Annually

"(5) On the first Wednesday of June, 1926, and the first Wednesday of June in each succeeding year, the joint committee of three representatives of the anthracite miners, the three representatives of the anthracite operators, and the three representatives appointed by the President to represent the public, shall meet at the request of either party, to adjust wages and conditions for the year beginning on the following first day of September, as herein provided in Paragraphs 4-A and 4-B.

"(6) The wage rates determined by the committee shall be for a period of one year, beginning upon Sept. 1, and if the committee is delayed in fixing rates through causes unforeseen beyond their control until after Sept. 1 in any year, there shall be no lockout or strike, and the decision when rendered shall be retroactive as of Sept. 1 of such given year.

"(7) The joint committee shall elect a chairman and secretary, with the right to join in discussions, but without power to vote, and the chairman shall have power to convene said committee at his discretion.

"(8) Rules and regulations for the conduct of meetings, as well as place for same, shall be agreed upon by the joint committee at the first meeting.

"(9) In case of death or disability or resignation of any appointee, the vacancy thus caused shall be filled by the party which named the appointee in the first instance.

"(10) The expenses of the committee shall be divided equally between the miners and operators."

At the opening of the conference the various other plans recently proposed were placed in the record. When the Markle program was laid before the meeting, opposition was voiced by the miners on the ground that the plan meant arbitration. The operators, on their side, reiterated the necessity for a settlement which would end periodic suspensions. Particular emphasis was placed upon the provisions of paragraphs 4-A and B. The chairman explained that these provisions were inserted to provide strict impartiality.

The miners wanted to know whether freight rates and selling prices would come in the scope of the Markle program. The reply was made that the fact-finding committee set up could not go outside the terms of the wage contract. The operators argued that any decision fixing prices would be illegal. The miners retorted that it was not fair to arbitrate wages and not prices.

The committee continued in session until nearly midnight and then adjourned until yesterday afternoon. Neither side would make any predictions as to the outcome.

### Attempt Conference at Scranton

For a few hours last week it looked as if the conference reconvened at New York on Dec. 29 would be anticipated by a meeting at Scranton under the auspices of the mayors and burgesses of the anthracite region. Following the Inglis letter of Dec. 20, in which it was stated that the operators accepted the invitation to resume negotiations provided that the miners abandoned their reported insistence upon the discredited Pinchot plan as the basis of settlement, Mayor Durkan of Scranton wired Mr. Lewis to meet with the operators at Scranton on Dec. 22. Late on the afternoon of Dec. 21, however, Major Inglis sent a second communication to the mayors and burgesses in which he said:

> It is necessary, to make our position perfectly plain, to remind you that the resolution under which your invitation to a meeting was authorized and issued specified that the conference was to be on "the understanding that either side shall be at liberty to bring up for discussion its own plan or plans, the Governor's plan or any other plan that may be offered."
>
> Mr. Lewis's response to your invitation stated that "if the mine workers enter a conference it will be upon the basis of the Governor's compromise."
>
> Our response to your invitation stated that we would attend the conference with-

## *Real Earnings of Contract Miners In Anthracite Fields—III*

(MADEIRA, HILL & CO.)

Are contract miners in the anthracite fields underpaid?

John L. Lewis, international president of the United Mine Workers, insists that they are. He has repeatedly drawn upon the reports of the Coal Commission, with their misleading figures basing earnings upon the number of starts made, to support his assertion. In a statement published in the Sept. 15 issue of the *United Mine Workers' Journal*, Mr. Lewis declared that the average was $1,700 per year, from which "there must be deducted over $200" for supplies.

Check of actual payrolls, however, tells a far different story.

The collieries of the anthracite operations of Madeira, Hill & Co. made 284 breaker starts in 1924 and employed 1,047 contract miners. Of this number, however, only 439, or 42 per cent, worked regularly enough to appear on each of the semimonthly payrolls. Of this number, 51 men averaged over $4,000 *net* for their labors. The lowest rated group averaged $1,276.71.

The average earnings by $100 groups for the 439 contract miners were as follows:

| Miners | Average Annual Earnings | Miners | Average Annual Earnings |
|---|---|---|---|
| 51....... | $4,004.98 | 32....... | $2,355.11 |
| 5....... | 3,455.91 | 40....... | 2,253.74 |
| 6....... | 3,345.50 | 27....... | 2,160.11 |
| 11....... | 3,245.80 | 21....... | 2,055.64 |
| 19....... | 3,142.65 | 18....... | 1,954.41 |
| 17....... | 3,046.83 | 20....... | 1,859.52 |
| 14....... | 2,945.31 | 16....... | 1,749.97 |
| 14....... | 2,857.49 | 9....... | 1,671.44 |
| 17....... | 2,742.36 | 6....... | 1,549.09 |
| 25....... | 2,645.61 | 5....... | 1,459.11 |
| 24....... | 2,542.97 | 2....... | 1,362.83 |
| 37....... | 2,454.41 | 3....... | 1,276.71 |

The average earnings for the entire group of 439 were $2,597.32. Forty-six per cent of the group made more than $2,500. Eighteen per cent fell below $2,000; men in this division worked less than 258 days and the lowest rated groups averaged 239 days. Average daily earnings ranged between $6.05 and $14.17 for an average day of approximately 6½ hours.

> out any conditions whatever provided that the miners accepted your invitation in the same sense and without reservation. The miners have failed to do this.
>
> Until you can give us written assurance from the miners that they are willing to enter conference on the basis of your invitation and without any reservation, we regret to say that we cannot attend the meeting suggested. Such a meeting would lead to nothing except misunderstanding and further delay. It is because we are most anxious that our attitude should be thoroughly understood that we have given in detail the reasons on which this reply to you is based.

### Lewis "Misunderstood"

Following the receipt of this letter, Mayor Durkan wired Mr. Lewis that the conference was off. Still later Mr. Lewis wired from his home in Springfield, Ill., that his position had been misunderstood. "Governor Pinchot," he said, "has urged that I clarify the wrong impression of the mine workers' attitude which has been brought about by improper interpretations. Accordingly you are advised that while the mine workers will enter the conference in the light of your invitation and in conformity with our telegrams to your committee, the presentation and advocacy of the Governor's plan does not prevent the consideration of any other plan or plans by the parties to the conference."

Before this telegram was made public, however, a bombshell was thrown into the miners' camp by the appearance of an appeal signed by sixteen Catholic clergymen, who said they represented "in a pastoral capacity 85 per cent of the miners of anthracite coal," declaring that the miners were tired of the suspension and wanted arbitration of all disputed points upon which the operators and the union were unable to reach an agreement. Failure of the operators and miners to get together, asserted the clergymen, had resulted in the irreparable loss of millions of dollars to employers and employees and to the public, a national prejudice against anthracite, loss of faith in the future of the anthracite region, danger to the health and lives of the workers and their families and a state of idleness producing a demoralized citizenry.

District leaders of the union displayed restrained resentment over the action of the priests, but in other quarters the statement was accepted generally as a true picture of conditions. The position taken by the pastors was indorsed the next day by eleven pastors of English-speaking congregations.

Shortly before midnight Christmas Eve, Alvan Markle, chairman of the joint conference, announced that a call had been issued for a meeting at New York on Dec. 29. Two days later full-page advertisements began to appear in the papers in the region offering to reopen the mines at once at the old wages and to continue that scale until next September.

## More Ships Switch to Coal

The U. S. Emergency Fleet Corporation will place additional coal-burning ships on its Oriole Line to United Kingdom ports, displacing oil burners. Arrangements to this effect are now in progress, according to statement last week by James F. Paige, assistant to the vice-president in charge of operations. This decision is due, it is understood, to the substantial savings effected by the substitution, several months ago, of four coal burners for oil burners. It is estimated that the entire cost of placing these four coal burners in spot condition will be recovered in less than 18 months through fuel savings. The reconditioned ships were part of what is known as the "laid-up" fleet.

## $6,000,000 Merger Plans 20,000,000 Ton Output

A consolidation of coal and dock properties that handled twelve million tons of coal this year was announced at Cleveland, Dec. 29, by Frank E. Taplin. It is the North American Coal Corporation, a holding and sales company whose incorporation papers were filed on Dec. 30. The new concern is capitalized at $6,000,000. It was said that three more companies were to come in early in 1926 to raise the output to twenty million tons.

Mr. Taplin's Cleveland & Western Coal Co. forms the nucleus of the North American Coal Corporation. The others included are the Powhatan Mining Co., the Pittsburgh Terminal Coal Co., the Standard Island Creek Coal Co. and three dock operating companies, the Inland Coal & Dock Co., of Duluth, the United Coal & Dock Co., of Milwaukee, and the Canada Coal Co., Ltd. The North American will be the selling agent also for W. C. Atwater & Co., of New York. The officers of the corporation are Mr. Taplin, president; William Taylor, of Cleveland, A. S. McQueen and C. E. Tuttle, of Pittsburgh, vice-presidents.

## Byproduct Coke Production Breaks Record in November

Output of byproduct coke in November, 1925, according to the Bureau of Mines, was 3,557,000 net tons, which is the highest on record, being an increase of 155,000 tons, or 4.6 per cent, compared with October. The coke plants operated at about 88 per cent of capacity. Including the new plant at Troy, N.Y., and the rebuilt plant at Chester, Pa., the number of byproduct plants in existence now totals 80, of which 74 were active during November.

Of the total production of byproduct coke during November, 2,953,000 tons, or 83 per cent, was made in plants associated with blast furnaces, and 604,000 tons, or 17 per cent, at merchant or other plants.

Beehive coke output in November totaled 1,213,000 net tons, an increase of 207,000 tons, or 20.6 per cent, compared with October. Byproduct plants contributed 75 per cent of the output of all coke in November.

### Eastman New I. C. C. Chairman

J. B. Eastman will become chairman of the Interstate Commerce Commission Jan. 1, under the rule of rotation by which the position is filled from among the commission members. Mr. Eastman, formerly a member of the Massachusetts Public Service Commission, was appointed to the federal body by former President Wilson.

### "Soo" Coal Traffic Lower

During the lake shipping season of 1925 11,974,347 net tons of bituminous coal and 899,989 tons of anthracite passed through the "Soo" Canals. This was a decline of 1 per cent in soft coal and of 37 per cent in hard coal as compared with 1924, when the totals were 12,126,252 tons and 1,439,701 tons.

## Reign of Terror Marks Christmas Observance In W. Va. Strike Zone

A reign of terror broke out in the northern West Virginia coal fields last week, which culminated in an unsuccessful attempt to destroy the steel girder bridge of the Western Maryland Ry. that spans the West Fork River at Bingamon, Marion County, at 4:30 a.m. Dec. 23. Nitroglycerine, police believe, was used to blow up the shoes on the bridge, with the result that the main span sagged to the middle pier of the bridge, which is 300 ft. long. The extent of the damage will not be known until the company engineers of Cumberland, Md., make an inspection of the damaged structure. Effort is being made by the railroad officials to make the necessary repairs to the bridge by early this week. Western Maryland detectives, state police and county authorities are at work on the case. No coal cars can be moved until repairs are made, but with the ease-up over the holidays there will be no serious tie-up. The Carolina mine of the Consolidation Coal Co. on the Helen's Run branch is in a position to work, this branch coming on to the Monongahela River branch of the Baltimore & Ohio at Chieftown.

A charge of dynamite is believed to have been hurled from a passing automobile under the house of Andrew Pawiski in Monongah on Monday night, Dec. 21, when a portion of the structure was blown away. The house is owned by the Consolidation Coal Co., and it is reported that Pawiski was previously threatened. Pawiski, who is a Polish miner, was among the first foreigners to work there, and it is thought that the demonstration was against any Poles breaking the strike there.

### Dynamite on Christmas Day

A third dynamiting incident occurred early Christmas morning when an attempt was made to destroy the home of John Bondo, a merchant of Monongah, who is working open-shop in the Monongah mine of the Consolidation Coal Co. Only windows in the home were shattered. The bomb was thrown from a passing automobile.

Fire of unknown origin destroyed a vacant double house of the Consolidation Coal Co. at Baxter early Sunday morning, Dec. 20. A loss of $4,000 was sustained. The Fairmont fire department responded and kept the flames from spreading to other buildings in the mining town.

Twenty thousand children in the 12½ counties of northern West Virginia were treated to candy, apples, oranges and nuts by the United Mine Workers on Christmas Day. Similar depots were opened in Grafton, Clarksburg, Morgantown and Tunnelton. Entertainments were held by many of the local unions and Christmas trees in many instances were trimmed in the barracks, including Grant Town, Dakota, Baxter, Barrackville, and other places. Addresses were made by international representatives at all of the Christmas gatherings. One of the largest attended gatherings was in the miners' hall at Monongah, where the union Sunday schools rendered Christmas carols on the evening of Dec. 23.

## *Plan Co-operative Selling In Western Kentucky*

Preliminary steps for the formation of a centralized sales organization for western Kentucky operators were discussed at a conference of about twenty-five producers from that field, held in Louisville, Dec. 16. A committee was named to study the matter and decide on the feasibility of the plan, after analyzing the legal technicalities surrounding it. Tentative arrangements were made for another meeting at an early date to continue the discussion.

Aaron Sapiro, who organized California and other Western fruit and vegetable co-operatives, the tobacco growers, cotton producers, potato shippers and others, outlined co-operative sales methods.

The plan, of course, is to terminate as much as possible the present policy of "loose selling." Any organization that may be formed will be separate from any existing body.

For two years or more western Kentucky operators have been discussing various merger proposals, none of which has been worked out satisfactorily yet.

Because of the holidays the coal production will suffer for the next week or more. Most of the coal mines closed down at the end of Wednesday and planned to resume Monday, Dec. 28. The lack of demand for coal, heavy accumulations and the trade facing the inventory season of railroads and industries, will curtail output.

In the first two days of last week 4,008 cars of coal was produced by non-union mines compared to 610 cars by union mines. There were 234 non-union mines at work Dec. 21, when they produced 2,001 cars of coal, while on Dec. 22 225 mines were active, and they loaded 2,007 cars of coal. Fifteen union mines worked both days, and on Dec. 21 produced 313 cars of coal and on Dec. 22, 297 cars.

The production while heavy during the beginning of the week slumped toward the week-end. In the first two days of the previous week the non-union mines loaded 3,862 cars of coal, while union mines produced 448 carloads. During that week 255 non-union mines were at work daily on the average and 14 union plants operated.

---

The Tidewater Power Co., Raleigh, N. C., and Southern Power Co., Charlotte, N. C., will ask for offers on an aggregate of about 300,000 tons of coal, mostly slack, for delivery in the near future. These companies have found themselves in need of coal for their auxiliary power systems, because of the extended drought of last summer and the consequent lack of proper water supply for their hydro-electric systems.

## Changes in Mines Committees In Both Houses

The membership of the Senate Committee on Mines and Mining for the Sixty-ninth Congress is made up as follows: Tasker L. Oddie, of Nevada, chairman; Thomas J. Walsh, of Montana; Coleman duPont, of Delaware; Henry F. Ashurst, of Arizona; Key Pittman, of Nevada; Guy D. Goff, of West Virginia; William H. King, of Utah; Lynn J. Frazier, of North Dakota; Robert M. LaFollette, of Wisconsin; Arthur R. Robinson, of Indiana. Ralph H. Cameron, of Arizona, has been transferred from the committee to a vacancy on the Appropriations Committee. Rice M. Means, of Colorado, also has retired from the committee to accept a place on the Committee on Public Lands.

The membership of the Committee on Mines and Mining of the House of Representatives is as follows: John M. Robsion, of Kentucky, chairman; Arthur H. Greenwood, of Indiana; William Williamson, of South Dakota; Mell G. Underwood, of Ohio; Don B. Colton, of Utah; Joseph Whitehead, of Virginia; Charles E. Winter, of Wyoming; Andrew L. Somers, of New York; W. H. Sproul, of Kansas; Butler B. Hare, of South Carolina; George F. Brumm, of Pennsylvania; Virgil Chapman, of Kentucky; J. J. Manlove, of Missouri; Arthur M. Free, of California; Edmund M. Carpenter, of Pennsylvania, and Dan A. Sutherland, of Alaska.

---

## Senator La Follette Seeks Hard-Coal Company Data

A resolution providing "that the Secretary of the Treasury be and he is hereby authorized and directed to furnish to the Senate a statement based on corporation income tax returns covering the year 1924, showing for each corporation engaged in the mining of anthracite coal the amount of capital stock, the amount of invested capital, the amount of net income, the amount charged to depreciation and depletion account and the amount of federal tax paid by each such corporation," was presented in the Senate at Washington Dec. 22 by Senator LaFollette. Upon objection of Senator Reed, Pennsylvania, the formal introduction of the resolution goes over, according to the regular Senate rule, until the next calendar day, which in this instance is Jan. 4. It will be noted that this resolution does not call for action by the House of Representatives.

---

## Massachusetts Dealers Have Coal for About a Month

Retail coal dealers in Massachusetts reported stocks of 178 000 net tons of domestic anthracite, 333,474 tons of bituminous coal and 34,127 tons of coke in their yards on Dec. 1. During November the dealers delivered about 187,000 tons of anthracite, 220,000 tons of bituminous coal and 28,000 tons of coke. The cumulative deliveries of anthracite by dealers in the first eight months of the coal year total 3,528,558 tons, which is about 69 per cent of the total deliveries in the last coal year.

# To Push Legislation on Hard Coal in Congress Even if Strike Ends Soon

**By Paul Wooton**

Washington Correspondent of *Coal Age*

Appeals in the Senate and in the House of Representatives for the consideration of coal legislation thus far have failed to elicit any promise or commitment from the chairmen of the committees having jurisdiction. Some idea, however, of the views of Representative Parker, chairman of the House Committee on Interstate and Foreign Commerce, has been obtained. Representative Treadway of Massachusetts, in the course of remarks on the floor of the House, said the public is being left out of the equation by the operators and miners, whom he held to be equally responsible for the present situation.

This led Chairman Parker, whose committee must take the first step in any legislation that has been proposed, to ask if thought had been given to the fact that anthracite is mined within the borders of a single state and that it is a matter which must be handled largely by that state.

When Representative Treadway declared that the Girard "trust" is taking the money for its "so-called" charities from the anthracite consumers, largely in states other than Pennsylvania, Mr. Parker again asked his significant question: "Will the gentleman point out how we can remedy that situation?" This brought from Mr. Treadway the admission that he simply was bringing that situation to the attention of the public. He added that he would bring under regulation that part of the anthracite production which enters into interstate commerce.

### Seeks Legislative Protection

Mr. Treadway commended strongly to members the recommendations of the Harding Coal Commission that anthracite be declared a public necessity and that full publicity be given the items making up the cost to the consumer. He made it clear that he will strive for legislation, even if the present strike should be settled in the near future, so that New England and other anthracite consuming states will know "whether they must learn to do without anthracite or, as an alternative, whether they can be protected so as to expect a continuous supply and at a price which they know to be fair and proper."

Congress was urged by the New England Representative to take action that may result in "freedom from the octopus of Pennsylvania greed, and when I say Pennsylvania greed, I refer to the state itself, exactly as much as I do to the operators and miners." If the state wants to show good faith, Mr. Treadway feels, it should repeal its export tax and its miners' licensing law and use its great power to change its royalty system.

In the Senate, Mr. Copeland, of New York, made an oratorical effort on behalf of those who are suffering as a result of the strike. He urged Congress to act in their behalf, but failed to suggest the form such action should take.

As this is written, Senator Oddie is awaiting Secretary Hoover's report on his Bureau of Coal Economics bill. With that report in hand, which may suggest extensive changes in the bill, it is Senator Oddie's intention to start public hearings.

In the meantime, much light is thrown on the condition of the country by the report on stocks issued by the Bureau of Mines, shown on another page.

George J. Young

Mr. Young, who for the past five years has been associate editor for *Engineering & Mining Journal-Press* with headquarters at San Francisco, will also serve in the future as Pacific Coast editor of *Coal Age*. Mr. Young is one of the authorities on mining engineering and mining methods, especially through his book on "Elements of Mining," which is published by the McGraw-Hill Book Co. It is considered the best work of reference on the subject. A volume by Mr. Young on "Underground Mining Methods" is now being published by Ernest Benn, Ltd., in London, the British publishers having especially requested Mr. Young to undertake this volume. Arrangements also have been made to publish it in the United States through the McGraw-Hill Book Co. Mr. Young is a graduate of the University of California, and in the course of his career has served as professor of mining at the Mackay School of Mines in Nevada and the University of Minnesota and as professor of metallurgy at the Colorado School of Mines.

---

## Consumers Company Floats Big Bond Issue

The Consumers Co., Chicago's largest retail coal concern, has sold to Halsey, Stuart & Co. $8,500,000 in securities, consisting of $6,000,000 first mortgage sinking fund 6 per cent bonds, due Jan. 1, 1946, and $2,500,000 6 per cent convertible gold notes, due Jan. 1, 1931, which are to be issued to the public soon. The financing is in accordance with plans decided when a reorganization of the financial structure of the company was effected, about six weeks ago. At that time Stuyvesant Peabody was elected president. The significance of this step was explained when it was stated that the Consumers Co. hereafter will be under the management of the Peabody Coal Co., of which Mr. Peabody is also president.

## Pittsburgh Coal Co. Soon To Reopen Sixth Mine In Smoky City District

The Pittsburgh Coal Co., it is reported on reliable authority, will reopen another mine in the Pittsburgh district on the 1917 scale within a week or so. This will give the company a total of six mines working on the 1917 scale in the Pittsburgh district. While the exact location of the new mine is not revealed it probably will be in Allegheny County, adjacent to the City of Pittsburgh, in which county the company already has two mines working.

The opening of the sixth mine, preparations for which are said to have been completed, is the result of the successful period of operation at the other pits of the company in this district. During the last few weeks the Pittsburgh Coal Co. has been averaging from the five operations in the neighborhood of 20,000 tons of coal per week, for which a ready market is obtainable, and the reopening of the additional operation will be in pursuance of the company's policy to gradually expand its operations until as many of the mines in western Pennsylvania are producing as it is possible to keep going.

In general, the actions of District No. 5, United Mine Workers, during the past few months have been passive in respect to the lower wage rate paid by the Pittsburgh company, but during the past week a number of reports have been current that some campaign toward the re-establishment of the Jacksonville agreement was being fomented in the union ranks.

On Dec. 24 the Pittsburgh Coal Co. distributed at its five mines the largest payroll since the resumption of operations on the 1917 scale. The total was $72,535.36, which with the distribution $60,043.37 to the miners on Dec. 12 makes a total of $132,578.73 paid in December. Midland mine, near Canonsburg, paid out the biggest sum distributed in any one of the company mines on Thursday, the Christmas pay there being $20,972.05. The average number of men participating was 274. Banning No. 2 mine, near West Newton, came next with $20,110.68 to an average of 257 miners. The payroll at Banning No. 1 was $16,996.90 to an average of 238 men and at Montour No. 10, at Library, $14,447.73 was paid to an average of 207 men. The pay at Mansfield was small due to the limited force of men there.

## 1,000 Gondolas for L. & N.

An order for 1,000 all steel drop-bottom coal cars of the gondola type was recently placed by the Louisville & Nashville R.R. with the Pressed Steel Car Co., Pittsburgh, at a cost of $1-800,000, it was announced at the office of the president of the road, at Louisville, Ky. The cars are to be delivered in March and April. This expenditure brings the total for new equipment, including passenger and freight cars and locomotives, ordered by the railroad within the last three months to $8,700,-000, according to the announcement.

# Consumers' Stocks of Bituminous Coal Total 48,000,000 Tons Nov. 1; Output Fails to Offset Anthracite Deficiency

Stocks of bituminous coal in the hands of consumers on Nov. 1 totaled about 48,000,000 net tons, according to a survey by the U. S. Bureau of Mines. This was slightly larger than in the corresponding period of 1924. On June 1, 1925, stocks were 38,000,000 tons. Between June 1 and Sept. 1, consumers added 5,000,000 tons to their total reserves, and between Sept. 1 and Nov. 1, another 5,000,000 tons. From the trend of production and consumption it is apparent that the flow of coal into storage has continued since Nov. 1.

At the rate of consumption prevailing in September and October, when busi-was active and consumption large, the stocks on Nov. 1 were sufficient to last 35 days. This compares with a supply of 45 days on Sept. 1, 1924, when business was dull; 46 days on Sept. 1, 1923, and 23 days on Nov. 1, 1922. These figures, of course, presuppose that stocks are equally divided, which never is the case.

In addition to the storage piles of consumers on Nov. 1, there were 7,512,000 tons of bituminous coal on the docks of Lakes Superior and Michigan, at least 221,000 tons held in storage by producers at the mines or intermediate points, and 503,850 tons in railroad cars unbilled at the mines.

*Anthracite.*—On Sept. 1, when the anthracite strike began, retail dealers had on hand a supply sufficient to last 53 days, at the rate they were delivering to their customers in September and October. By Nov. 1, retail stocks of anthracite had been reduced to 27 days.

A group of 21 byproduct coke plants, selling domestic coke, available as substitute for anthracite, reported 599,000 tons of coke in stock on Nov. 1.

The estimate of soft-coal stocks is based on practically complete reports from the byproduct coke works, steel plants, and railroads, and on reports from a selected list of other consumers—about 5,000 in all. The estimate takes no account of coal in the bins of householders, concerning which no statistics are available, nor steamship fuel, nor the tonnage on the Lake docks, which latter item is included under "Coal in transit."

As shown in Fig. 1, the total stock on Nov. 1 was slightly higher than on Sept. 1 of last year, the nearest comparable record in 1924. It was about equal to the level of stocks in the fall of 1921, much above that in 1922, after the great strike of that year, and much less than that of late 1923, when consumers were laying in reserves in fear of another strike.

The average rate of consumption plus exports for the two months of September and October was 10,500,000 tons of bituminous coal per week. This high rate indicates activity among the coal-using industries and also a considerable substitution of bituminous coal for anthracite.

### Charts Show Large Stocks

In studying the figures of days' supply by classes of consumers, shown in Fig. 2, it should be borne in mind that they are averages and fail to show the great variation between different plants and even different communities.

Fig. 3 shows how the reserves of soft coal in terms of days' supply varied from state to state on Nov 1. For this purpose the general industrial plants, other than steel and byproduct coke works, give the best indication, because they form both the largest group of consumers and the one most responsive to changes in the coal market. New England was heavily stocked with coal, every state showing over 90 days, the average for the region as a whole being 110 days. Stocks in the northern peninsula of Michigan likewise were very large. In New York State stocks averaged 78 days, in lower Michigan 63 days, in New Jersey 59 days. All other states show reserves for less than 60 days' supply.

Public utilities, as usual, carried heavier reserves than any other class of consumers. The supply at coal-gas plants on Nov. 1 was sufficient, on the average, for 78 days, and at electric central stations, for 46 days.

Complete returns from manufacturers of byproduct coke and steel indicate the following reserves:

### Byproduct Coke Plants

| | Days' Supply | | |
|---|---|---|---|
| | Sept. 1, 1924 | Sept. 1, 1925 | Nov. 1, 1925 |
| Low volatile | 33 | 18 | 28 |
| High volatile | 29 | 23 | 26 |
| Average... | 30 | 22 | 26 |

### Steel Plants

| | Days' Supply | | |
|---|---|---|---|
| | Sept. 1, 1924 | Sept. 1, 1925 | Nov. 1, 1925 |
| Steam coal.. | 36 | 30 | 31 |
| Gas coal.... | 56 | 33 | 33 |
| Average... | 42 | 30 | 32 |

Each group had a larger tonnage in stock on Nov. 1, 1925, than on Sept. 1, 1924.

The total quantity of railroad fuel on hand Nov. 1, according to the American Railway Association, was 10,600,000 tons, a supply sufficient to last 30 days.

All coal brought to the surface and not yet delivered to a retail dealer or a consumer may be considered in transit. The largest element in this mobile reserve is the coal in railroad cars, which, though it has never been accurately measured, is known to run into millions of tons and to be subject to sudden and wide fluctuations. Because of the heavy production in late October, the quantity of bituminous coal on wheels on Nov. 1 probably was two million tons greater than on Sept. 1 and eight million tons greater tran on June 1.

Storage at the mines is practiced by few producers and the quantity so stored at present is small. From a list of 43 companies who have at some time stored in quantity at the mines or at some intermediate point, the Bureau

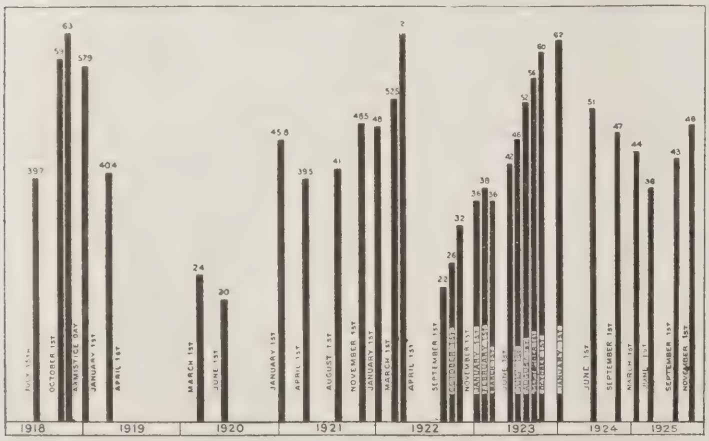


**Fig. 1—Total Commercial Stocks of Bituminous Coal, Oct. 1, 1916-Nov. 1, 1925**

Figures represent million net tons and include coal in the hands of railroads, industrial consumers, public utilities and retail dealers. Coal for steamship fuel, on Lake Docks, in transit and in the bins of householders is not included. From June 1 to Nov. 1 stocks increased about ten million tons, bringing the total back to the level of September, 1924. Reports are to the effect that since Nov. 1 further additions to stocks have been made.

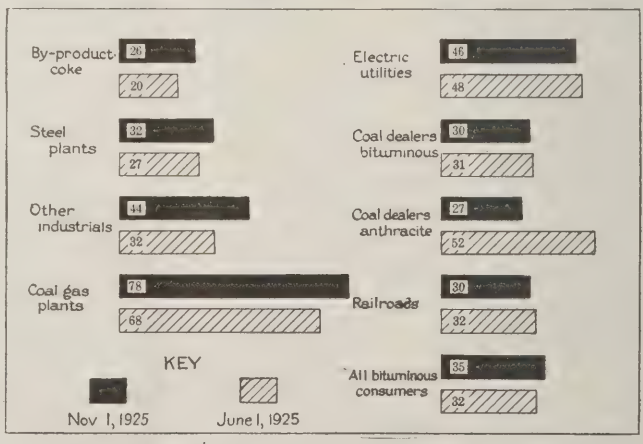

**Fig. 2—Days' Supply Held by Different Classes of Consumers June 1, 1925, and Nov. 1, 1925**

At the same time that the stocks of bituminous coal measured in tons were increasing, the rate of consumption also was increasing, so that measured in days' supply the reserve on Nov. 1, 1925, was not much greater than on June 1. The figures for June 1 are based on the rate of consumption in March, April and May, and the figures for Nov. 1 on that of September and October.

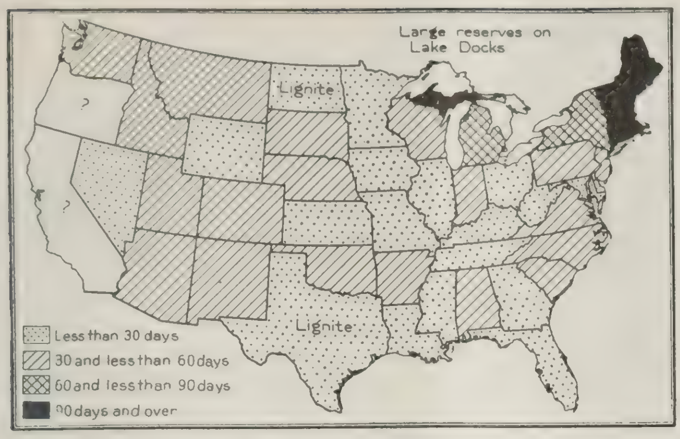

**Fig. 3—Days' Supply of Soft Coal on Hand at Industrial Plants Nov. 1, 1925**

This diagram shows state by state the distribution of the 44 days' supply of soft coal held at industrial plants, other than steel and byproduct coke works, on Nov. 1, 1925. New England, New York and Michigan stand out as areas of heavy reserves. Over the rest of the country, stocks are sufficient for less than 60 days.

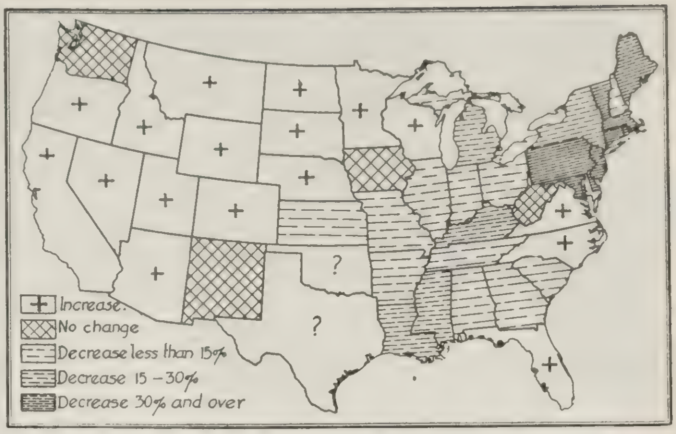

**Fig. 4—Changes in Retail Dealers' Stocks of Anthracite and Bituminous Coal Combined, Sept. 1 to Nov. 1, 1925**

Although retailers' stocks of bituminous coal increased from Sept. 1 to Nov. 1, the increase was more than offset by the decrease in stocks of anthracite. The total coal in dealers' yards therefore declined. In New England and the Middle Atlantic States the decrease generally exceeded 30 per cent. In the Middle West it was less. Most Far Western states gained.

**Days' Supply of Bituminous Coal in Hands of Various Classes of Consumers in the United States, Jan. 1, 1919, to Nov. 1, 1925 (*a*)**

(Figures represent number of days that supply would last at rate of consumption at time of stock taking)

| | Jan. 1, 1919 | June 1, 1920 | Aug. 1, 1921 | Nov. 1, 1921 | Sept. 1, 1922 | Nov. 1, 1922 | Sept. 1, 1923 | Oct. 1, 1923 | Sept. 1, 1924 | June 1, 1925 | Sept. 1(*b*), 1925 | Nov. 1(*b*), 1925 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|

(*a*) These figures are based on incomplete data. (*b*) Calculated at average rate of consumption in September-October. (*c*) No data. (*d*) Subject to revision.

has received reports of only 221,000 tons in stock on Nov. 1. In March 1923, these 43 companies had on hand 808,000 tons.

Reports from all of the companies show stocks of 7,512,000 tons on the docks of Lakes Superior and Michigan on Nov. 1. Though less than the heavy reserves accumulated in the fall of 1921, this compares favorably with other recent years, as is shown by the following totals: Nov. 1, 1921, 8,824,000 net tons; Nov. 1, 1922, 2,772,000 tons; Oct. 1, 1923, 6,862,000 tons; Sept. 1, 1924, 6,600,000 tons; Sept. 1, 1925, 6,366,000 tons.

The 21 byproduct coke plants supplying gas for city use report 599,000 tons of unsold coke on hand Nov. 1. The stocks on other recent dates have been: March 1, 1922, 987,000 net tons; Oct. 1, 1923, 476,000 tons; Jan. 1, 1924, 772,000 tons; Sept. 1, 1924, 1,114,000 tons; March 1, 1925, 606,000 tons; June 1, 1925, 694,000 tons; Sept. 1. 1925, 832,000 tons.

Unlike bituminous coal, considerable quantities of anthracite are stored at the mines or at intermediate points en route to consuming centers. The Bureau of Mines has been unable to obtain complete figures of such stocks as of Sept. 1, when the strike began.

There are no statistics on householders' stocks, but from the available facts as to production and shipments, it appears that the quantity in the cellars of householders was at least up to normal when the strike began.

On Sept. 1, when the strike began, retail dealers' stocks of anthracite were large. It was not possible to obtain reports from all dealers, but a selected group of representative dealers, who have been reporting regularly for seven years, had more anthracite in stock than on the corresponding date of 1920, 1921, 1922, or 1923, and nearly as much as in 1924.

Since Nov. 1, production of anthracite has continued practically zero. Production of bituminous coal during the succeeding seven weeks averaged around the very high rate of 12,400,000 tons per week. How much of the apparent surplus of bituminous production over bituminous consumption has gone to replace anthracite and how much to increase industrial stocks of bituminous coal is not known.

## Industrial Coal Consumption Declines in November

The industrial consumption of both anthracite and bituminous coal in the United States for November declined 25 per cent from the October level, according to the National Association of Purchasing Agents. This counteracts, to a certain extent, the estimated 26 per cent increase during October over the September figure. The November consumption is estimated at 37,464,000 tons. A total of 67,433,000 tons was on hand in industry Dec. 1. This is enough to last 54 days at the November daily rate of consumption of 1,249,000 tons. This is a great improvement over the situation last year, when 36½ days' supply was on hand Dec. 1.

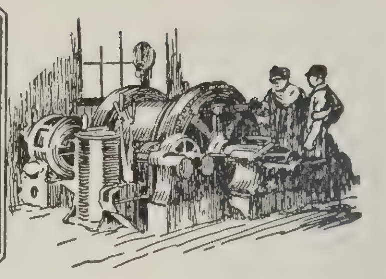
## Associations Decry Shipment On Consignment

A joint conference committee, on which the National Coal Association was represented by A. W. Calloway, president, Davis Coal & Coke Co., Philadelphia; H. N. Taylor, president, United States Distributing Corp., New York City; Ezra Van Horn, general manager, Clarkson Coal Mining Co., Cleveland, and T. F. Farrell, vice-president, Pocahontas Fuel Co., New York City (substitute for W. D. Ord), and the American Wholesale Coal Association by H. K. Cortright, president, Cortright Coal Co., Philadelphia; H. J. Heywood, Toledo, and Ira C. Cochran, Washington, president and commissioner, respectively, of that association, met Dec. 16 in the offices of the United States Distributing Corp., 17 Battery Place, New York City, to discuss the practice of open consignment of coal.

At this session the wholesale representatives called attention to the fact that, while last spring there was some curtailment of the practice of open consignment, yet during the past few weeks it had again grown rapidly. It was urged that the practice undoubtedly ties up and detains coal cars, congests terminals and otherwise interferes with the orderly functioning of the industry in getting its coal to market. After an extended discussion a resolution was passed to the effect "That this committee while not in any manner desiring to make any recommendation that will influence or affect either the quantity of coal produced or the price at which it should be sold, does in its judgment believe that in the interest of economy, efficiency and proper business practice, no coal should be shipped to any market except to fill bona fide orders for same."

There was a discussion as to the advisability of the co-operation of the two associations in case of any emergency and the joint committee was adjourned to meet at the call of the two chairmen.

# Practical Pointers For Electrical And Mechanical Men



## Home-made Nip Easily Connects Cutting Machine Cable to Trolley Wire

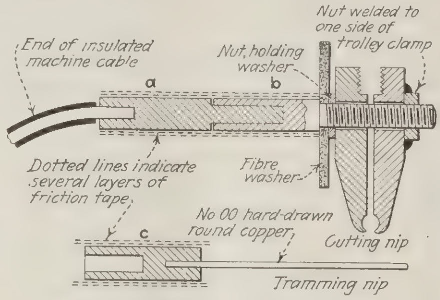
When Carson King, chief electrician of the Gatliff Coal Co., Gatliff, Ky., handed a new type of nip to one of the machine men and asked him to give it a trial, he annexed some extra work. The other operators besieged him to make nips of that type for their cutting machines.

The photograph indicates how the nip is used on the end of a machine cable to make connection to the trolley wire. With this device there is no need to make the connection at a hanger, because being on the wire it does not interfere with the trolley wheels of passing locomotives. The nip is easily attached to the wire, is just as easily taken off, and makes a good connection.

For tramming, a straight piece of No. 00 copper about 15 in. in length is substituted for the clamp. The change is made by means of a plug connector in the handle. This feature is shown in the sketch. Parts *a* and *b* could have been made as one piece and arranged for fastening the tramming wire to the end, but this construction would have made the device rather heavy. A tramming nip should be as light as possible otherwise when moving long distances the operators' arm will be tired by holding it up against the wire.

**Nip Clamped on a Trolley Wire**

It makes a tight connection and does not interfere with the trolley wheels of passing locomotives. The machine man does not have to make the connection at a hanger, but can fasten at any convenient point on the wire.



Nut welded to one side of trolley clamp
End of insulated machine cable
Nut holding washer
a
b
Dotted lines indicate several layers of friction tape
Fibre washer
No 00 hard-drawn round copper
Cutting nip
c
Tramming nip

**Sketch Showing Construction**

A Perfection trolley clamp was used in making the cutting nip. When tramming, part *b* is pulled off of *a*, and part *c* substituted. The plug connector is of a tight fit so as to not come loose accidentally.

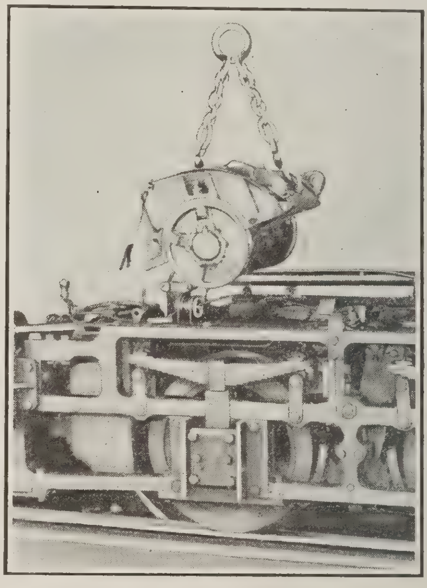
In the particular nip shown in the photograph a Perfection trolley clamp was used. The clamping-bolt hole, was reamed out to accommodate the brass stud. Any clamp of the same general type could be used. The nip is fastened to the wire by turning the handle *b* while the clamp is in position on the wire. The brass stud, screwing into the nut which is welded to one side of the clamp, brings the two halves together, making a tight connection to the wire.

## Locomotive Armature Is Easily Removed

Ordinary methods used to lift armatures from mine locomotives are not only awkward but dangerous to the armature windings, commutator and workmen. The motor is always in a tight place, and to remove the upper half of the frame, slip chains under the ends of the shaft to lift the armature from the lower half of the motor, requires much time and effort. Unless more than usual precaution is taken, the chains invariably squeeze and cut the ends of the windings, and quite often scratch and cut the ends of the commutator. In some instances the sling will slip off altogether, and in so doing injure the workmen. If it were possible, most workmen would take the pains to use a small steel sling to go under the ends of the armature shaft, but that is not a safe method and is quite difficult.

### ARRANGEMENT AIDS SAFETY

Special provision for the safe and quick removal of armatures has been made on a popular type locomotive shown in the illustration. The locomotive has motors with split frames bolted around the housing, and to remove the armature all that is necessary is to take out the bolts holding the top half of the motor frame to the lower section. The entire top half, armature and all, can then be safely lifted out. In the top half of the motor frame two eyes are specially cast for this purpose.



**A Safe Way to Take an Armature Out of a Locomotive**

The upper half of the motor casing together with the armature are removed at once by this method. With this arrangement the armature can be removed easily and safely.

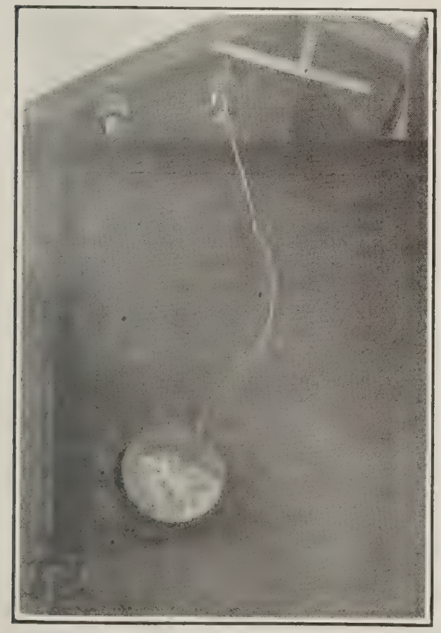
When safely out of the locomotive and on a bench, two bolts at each end release the frame section, and the armature is completely free to be repaired, without a chain ever having touched it, and within half the time usually required to perform this operation.

## Whistle Warns Engineer If Fan Slows Down

Simplicity, and a dependency on unfailing natural forces are points to be admired in any mechanical device. The old saying, "Nature abhors a vacuum," and the never-ending struggle of "Mother Earth" to pull everything closer to her bosom, explain the action of the whistle-blowing devices used on the two mine fans located near the tipple of the Woodward Iron Co.'s mine at Mulga, Ala.

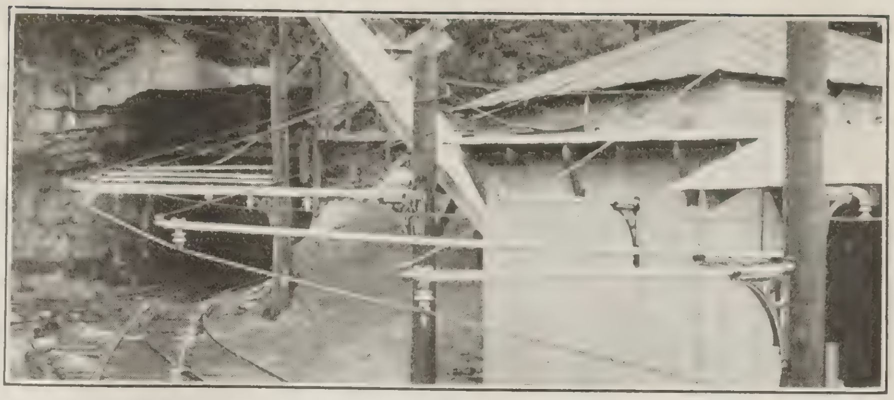
The whistles call the power house engineer if for any reason either fan should stop. Each fan is equipped with both steam-engine and motor drive. Square-jaw clutches provide for changing quickly from one drive to the other.

The alarm device is shown in the photograph. A hole was cut in the fan housing and a short, 6-in. diameter nipple attached by means of a standard flange. The end of the nipple is covered by a piece of oak 8 in. in diameter by 2 in. thick, to which the whistle wire is fastened. This wooden block is held over the opening by atmospheric pressure. The end of a nail projecting slightly out of the side of the block, so as to rest on the bottom side of the nipple, aids in keeping the block from working off due to vibration. Any appreciable reduction in vacuum allows the block to tip sidewise and fall off, thus blowing the whistle.



**Wood Block Falls If Fan Slows**

The fan operates exhausting. In order to show the 6-in. opening beneath, the wooden block was pushed slightly to one side. The wire extending from the upper arm of the bell crank goes to the steam whistle.



**Permanent Trolley Construction at a Tennessee Mine**

At this mine operated by the New Caryville Coal Co., Carryville, Tenn., the outside trolley is supported by pipe bracket arms fastened to large locust poles. Standard cast-iron brackets and regular outer-end castings are used in connection with 1½-in. galvanized pipe. On the curves, as many as three arms are fastened to each pole.

## Simple Mistake Holds Up Important Work

Often the troubles encountered in putting a new piece of equipment in service are caused by some simple mistake which has passed unnoticed until hunted down. This was well illustrated by the failure to obtain proper voltage on one of our power lines because of an error in making a tap connection.

At one of our mines, during the first part of December, 1924, when snow was beginning to fly, orders suddenly came to rebuild a power line which recently had been abandoned. The line had originally been used to supply electricity for a fresh-water centrifugal pump located half a mile from the main road.

When the line was taken down the plan was to drive the pump by steam until details of a more elaborate electrical system could be worked out. In September, when the anthracite strike was declared, the supply of fuel was cut off and recourse to electricity was necessary.

Men were quickly summoned to reconstruct the power line. The old steel poles which had been taken down but a few months previous were again set in position on their original foundations. Because the line voltage now available was higher than that formerly used, 4x6-in. lumber was bolted to the poles to serve as crossarms to which new insulators were attached.

In a few days the line was completed and two transformers connected in open delta were put in position near the pump to reduce the voltage to that required by the motor. When all was ready, power was shut off the main line and the branch circuit was attached.

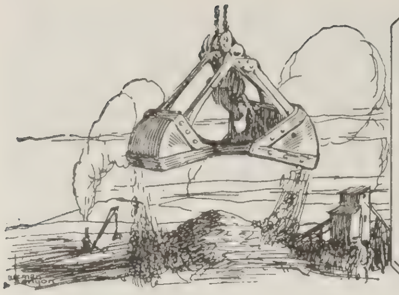
The following day the transformers were energized and a voltage test was made on the low tension side. Much to the surprise of everyone the phase readings were 450, 450 and 0 volts. After the high voltage wires were interchanged the readings were 450, 450 and 900 volts. Two primary wires were again reversed and the indications became 450, 450 and 0.

**Wrong Connection Caused Trouble**

When the branch circuit was connected to the main supply line two of the tap circuit wires were attached to the same main power conductor. This error caused much delay.

As the transformers were "borrowed horses," having been leased, it was thought that there was something internally wrong with one of them. However, it was noticed that the voltage readings obtained during the test did not bear the familiar 1.73 ratio to one another when the windings of three-phase systems ordinarily get mixed up. All indications were that one single-phase voltage was either neutralizing itself or doubling itself. This really was the case, the lineman having connected two of the branch circuit wires to one of the main supply line conductors, as shown in the accompanying illustration. Thus a puzzling difficulty which was easily caused was quickly remedied after about a day's loss of time.

M. A. THOMAS,
Hazleton, Pa. Engineer.



# Production And the Market

## Outlook Brightens as Trade Marks Time; Hard Coal Substitutes Firmer

As might have been expected by close observers of coal-market activities, business during the last week has been marked by the usual year-end tendency to mark time while plans are in preparation for a fresh start, with the possibility of facing new problems and conditions with the dawning of a new year. Needless to say, the year just closing has brought to the trade its share of disappointments in the way of blasted hopes, due in many instances to grandiose expectations of a happy hunting ground based upon the belief that the suspension of mining in the anthracite field would bring about a mad scramble for coal of any kind by panic-stricken consumers.

### Public Profits by Experience

The usually wise old gentleman of hallowed memory who characterized the public as an ass no doubt would be greatly surprised if he could now observe the comparatively indifferent attitude of hard-coal consumers, a large proportion of whom laid in fuel in advance of the strike or cheerfully turned to substitutes when their customary fuel was unobtainable at normal prices—quite a contrast from the distraught atmosphere prevailing during previous upheavals. In addition to the satisfaction of successfully combating a vexing problem and avoiding discomfort many will enjoy a considerable saving on their fuel bills. An interesting chapter in the drama remains to be written, of course, and this has to do with whether a new agreement terminating the strike if and when arrived at can be formulated that will give sufficient assurance of uninterrupted operations to enable the producers to win back the trade they have lost.

A touch of cold weather beginning early last week served to preserve a semblance of firmness in the price situation, and a further drop in temperature later brightened the outlook considerably. The softening tendency of almost record coal production also is feeling the counteracting effect of curtailed running time due to observance of the holidays.

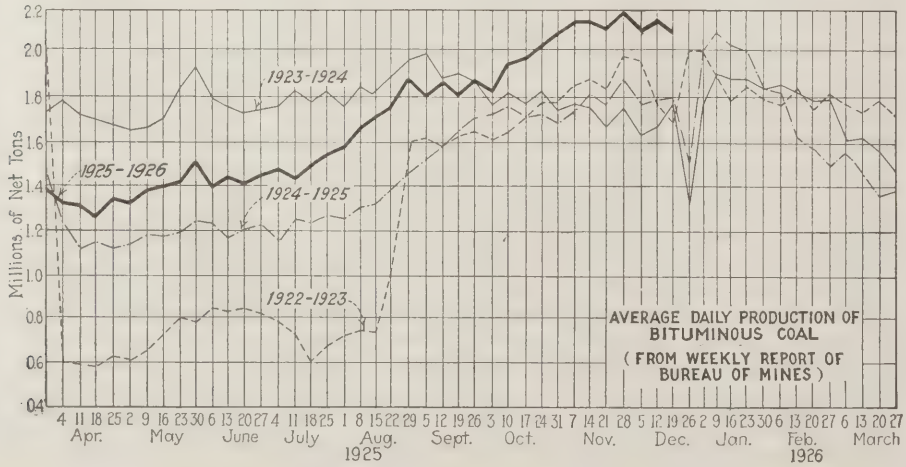
Activity in anthracite substitutes seems to have taken a new lease of life since Governor Pinchot's efforts for peace showed a likelihood of dragging a while before getting anywhere. Coke demand and prices continue their recent upturn. It is too early as this is written to be able to say whether this week's conference of operators and union leaders presages an early resumption of work at the mines or just a renewal of the indoor hammer throwing.

### Output Hovers Over 12,500,000 Tons

Output of bituminous coal during the week ended Dec. 19 is estimated by the Bureau of Mines at 12,600,000 net tons, a decline of 314,000 tons from the total for the preceding week but nearly 1,800,000 tons above that of the corresponding week of last year. Anthracite production in the week ended Dec. 19 totaled 55,000 net tons, compared with 64,000 tons in the previous week. Hard-coal output during the calendar year to Dec. 19 is 62,064,000 tons, or about 29 per cent less than in the corresponding period of 1924.

*Coal Age* Index of spot prices of bituminous coal stood on Dec. 28 at 178, the corresponding price being $2.16, compared with 179 and $2.17 respectively on Dec. 21.

Dumpings of coal at Hampton Roads during the week ended Dec. 24 totaled 446,093 net tons, as against 457,157 tons in the preceding week.



### Estimates of Production

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Minus two days' production to equalize number of days in the two years.

### Midwest Trade in Depths

Though there were a few days of cold weather last week, the Midwest market is duller than it has been for three months. Dealers are holding off purchasing until after the first of the year. The running time in the Illinois and Indiana fields has been very poor, some mines running not more than two days a week, and there are heavy accumulations of "no bills" on track. This does not worry the operators much, however, as they feel that the first real cold snap will clean up these quickly. Prices in the Illinois and Indiana fields are being held firm, as it is doubtful whether the coal could be moved even if a concession were made in price. While every operator has difficulty in moving prepared coal, there is quite a demand for fine coal, which is, however, very limited. Prices on this coal have gone up considerably, screenings bringing as high as $2 for Franklin County, $1.75 for Fourth Vein Indiana, and $1 for west Kentucky.

West Virginia operators are offering their coal at unheard of prices to keep their mines going. When 4-in. lump is offered as low at $1.85, conditions are not at all healthy. However, they all figure on a break that is bound to come with a change in the weather.

The Pocahontas operators have been hit the hardest. Whereas they were getting $4.25 for prepared sizes a year ago, today they are begging for business and $3 and even less, has been quoted quite frequently. Wholesalers who specialize in Pocahontas coal have no difficulty in placing orders with large operators at $3.25 for lump, egg and nut, and the majority of the operators are running their mines three or four days a week at the most.

Seasonable weather is beginning to move southern Illinois coals that have been dragging. Lump, of course, is beginning to move first, and this is pretty well cleaning up "no-bill" lump on track in the Williamson and Franklin County fields. There is some call for egg, but nut and screenings are slow, although screenings have been pretty well cleaned up recently while the other sizes were sluggish. Railroad tonnage is fairly good from the shaft mines and some is moving from the strip mines. Car supply is good, movement of coal fair and working time ranges from three to five days a week. Similar conditions exist in the Duquoin and Jackson County field. There has been no change in prices excepting those of the strip mines, which vary weekly in meeting competition.

In the Mt. Olive field there has been a sudden pick-up in both steam and domestic. This field was heavily taxed with "no bills" until last week, when these began to move out. Working time is about 50 per cent here and railroad tonnage has dropped off. In the Standard field, even with colder

**Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines**

| | 1925 | | | 1924 |
|---|---|---|---|---|
| | Dec. 28 | Dec. 21 | Dec. 14 | Dec. 29 |
| Index | 178 | 179 | 182 | 171 |
| Weighted average price | $2.16 | $2.17 | $2.20 | $2.06 |

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1924, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

---

weather, there is no great change. A little more coal is moving but there is still a surplus of all sizes available. Working time ranges from three to four days a week and prices are about the cost of production. Railroad tonnage shows some improvement in this district. With colder weather coming and decreased tonnage at the working mines, there is likely to be a shortage before long, which may boost prices.

Colder weather has stimulated the St. Louis market to some extent and this is best evidenced in the pick-up of wagonload steam, which got off to a good start last week. Carload steam is fair, a few plants putting in a little storage and other plants cleaning up for inventory. Country steam is quiet, a little moving to Kansas City, and some steam nut to Omaha and some cheap priced coal to Chicago and the Twin Cities. Domestic locally is fairly good on middle-grade coals. Standard also shows considerable movement while smokeless and anthracite are slow and coke moving fairly well. Country domestic is good, everything considered. All sizes are moving in proportion and there is a fairly good country demand for coke. Locally the coke supply is pretty well cleaned up excepting what is being held and reserved for January, and local shippers have nothing to offer for Northern or Eastern shipments. No change in prices.

### Outlook Bright in Kentucky After Holidays

Cold weather and snow early last week in Kentucky along with usual holiday retail business brought some demand from retailers on coal rolling, or on local tracks, and it is believed that with production lower as a result of the holiday season, there is a good chance that prices will be higher by 25c. a ton soon, if the present weather lasts.

There appears to be an easing up in steam demand over the holiday or inventory period, some industrial plants slowing down their output. Heating demand is picking up and the utility companies are using increased supplies.

Prices are firm on all western Kentucky sizes, and in fact a trifle stronger on mine-run and screenings. In eastern Kentucky prepared has been a trifle weaker on account of West Virginia competition and lower quotations.

Principal quotations on eastern Kentucky 4-in. block are $2.50@$3.25, but some stock is quoted higher. Lump and egg are around $2.15@$2.50, some quotations being $2.25@$2.75; nut, $2@$2.50; mine-run, $1.50@$1.75; screenings, $1@$1.35. In western Kentucky 6-in. block is $1.85@$2.15; lump and egg, $1.75@$2; nut, $1.35@$1.50; screenings, 90c.@$1.10. Western Kentucky mine-run is firmer, some houses quoting at $1.25, but not much stock is to be had at under $1.35 and some is at $1.50 or better. Western Kentucky screenings are scarce and commanding better prices.

### Northwest Trade Unchanged but Firm

The Duluth-Superior market is firm and unchanged all through the bituminous list. The feature in the trade continues the heavy demand for Pocahontas and other smokeless coals as substitutes for anthracite. Pocahontas lump, egg and nut are quoted at $8.50 and mine-run at $5.50. Anthracite prices are firm and just as they have been since early last summer. On account of the greater use of substitutes and mild weather conditions it is now figured that anthracite will be available upon this market in a limited way up till early in February.

Shipments of coal from the docks are keeping well up to the average for the season though the weather has been comparatively mild during the last ten days. A substantial improvement in the movement after the opening of the new year is expected, as retailers and the larger consumers are reported to be carrying comparatively small stocks. Orders booked for early January shipment are said to have reached a good total.

An encouraging feature is the better interest shown by independent iron operators on the Minnesota ranges. Larger tonnages of steam coal are being supplied to utilities on account of low water. Industrial demand is expected to show marked expansion early in the new year.

With anthracite out of the reckoning, the fuel market in Milwaukee seems to have steadied for the weeks of real winter which are now at hand. The demand is brisk because of the weather, and of course may be expected to become more lively as the mercury dips. Coke has taken the place of anthracite and is steady at $15 for range, $14 for nut and $12 for the pea size.

Autumn business in the Twin Cities has been steady, with a gradual gain toward former conditions. Until there is some method of readjustment of inequalities of freight charges, the industrial situation is bound to be restricted and of limited activity. The retail situation is good. Buying is steady and constant, and the weather so far has been free from extreme changes that would bring about a rush of orders to be delivered at once.

### Southwest Has Partial Pick-Up

Kansas lump, which had accumulated on tracks, started moving with the return of cold weather, and the tracks soon were cleared. Arkansas, however, did not fare so well. There the mines continue to add to their record of idle time. Arkansas semi-anthracite lump is moving slowly, with no immediate prospect of improvement; mine-run is easy, and screenings are short. The Arkansas market is not expected to improve until some time after the first of the year, when bins filled early in the fall have begun to get low. Arkansas prices are unchanged at $6@$6.50 for lump; $2.75@$3.50 for mine-run and $2@$2.25 for screenings. Kansas nut has been easy, with screenings a little short. Kansas mines have lost little time this season.

The Colorado market appears to be a little soft due to warm weather in Missouri River territory. Domestic orders are being held back as bins are pretty well stocked. Production in Colorado in November was 1,167,000 tons compared with 988,000 tons for the same month a year ago. The average number of men employed in the mines was 11,829 and the number of days worked per mine was 157.9.

The market served by the Utah mines, which has been quiet for several weeks, is improving with more seasonable weather. Working time at the mines for the past week was a little above 50 per cent. A leading retailer reports a better market for domestic lump than straight lump. It is estimated that there were about 300 "no bill" cars on the tracks this week. Slack is a little scarce, but not as a result of market conditions so much as short working time at the mines. Demurrage rules were recently suspended, but the "no-bill" rule is in force again, which means that loaded cars are regarded as cars on hand when empties are apportioned by the railroads.

The metal mining and smelter industries and the railroads are most active in the market now. There is an abundance of labor at the mines, and many men are turned away regularly.

### Smokeless Revives in Cincinnati

Any bright spot to be found in a glum situation on the Cincinnati market is due to the way smokeless has been acting. For a month the skids seemed well greased for low-volatile prices, but just before Christmas the brakes seemed to hold and, even better, there was a sign of a rebound. Most of this is traceable to demand from the East after the futility of Governor Pinchot's efforts for peace in the anthracite field became apparent. Mostly nut and egg were wanted, with Canada partaking of the demand. With shutdowns and other conditions helping, nut went up to $4.50 for spot, egg climbed over the $4 mark with $4.25 paid for first-grade Pocahontas. Lump, usually the strongest of the preferred, still lags, though it bettered itself by 25c. Mine-run with holiday shutdowns in prospect, stiffened, some tonnage going as high as $2.65. Slack still is trying to find itself with no change.

Overproduction—shown glaringly in the American Railway Association report of 13,862 loads passing through the Cincinnati gateway, or an increase of 555 cars on an overstuffed market—explains why there have been some marked reductions in price for high-volatile domestic sizings. Refusals have been coming in from many points, Michigan being, possibly, the worst offender. Distress coal again is setting the spot price, dragging other good fuel along with it. Some lump went below $2, some egg below $1.75, weakening straight sales also. In contrast to this, mine-run and slack are holding up well. About the only break in the latter is in Kentucky low grades, some of which have sold down to 90c. under pressure of competition.

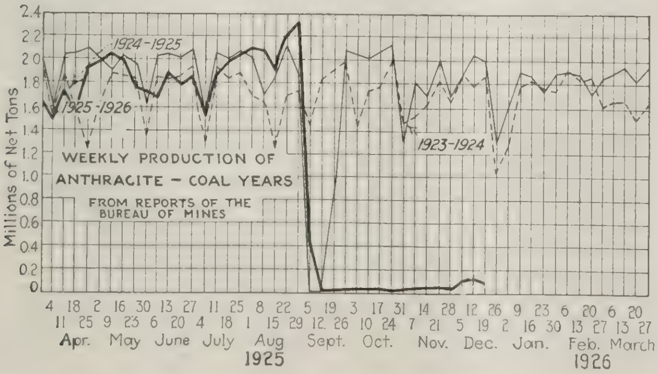
Retail trade shows little or no change other than the spurt for small deliveries caused by snow and cold weather just before Christmas. River business continues in an even channel.

Demand for domestic grades has been rather dull in Columbus and vicinity during the past week. Dealers are pretty generally stocked and householders are going slow in placing orders, but retail prices have not declined. There is a considerable amount of free coal on the market and the tonnage of consignment fuel is increasing not only in Columbus but in Toledo and Detroit.

Large steam users are buying for current needs only. There will be little doing in contracting before March. Utilities are good purchasers and iron and steel plants are also in the market. Screenings are holding up exceptionally well.

Production in the southern Ohio field averages about 25 per cent of capacity, with the Pomeroy Bend district showing up the best.

Market conditions in eastern Ohio are more sluggish. Screenings prices have advanced to $1.50@$1.60, other quotations being soft. Most of the mines closed from Thursday till Monday. Production fell away the week before. As retailers are fully stocked and steam buyers holding off, operators are pessimistic as to the immediate future.



### Conditions Quiet at Pittsburgh

Demand for domestic coal from the regular territory of the Pittsburgh district has been rather poor. Railroad and industrial demand have been moderate, consumption being fully as great as could be expected. There is but little outside demand for Pittsburgh district coal. The call of the East, such as it is, now runs to "nut" coal. On the East's last buying the movement was chiefly in "egg" but it seems the operators had altogether too large eggs in mind, sizes running up to 4-in.

With the figures for the last week in December estimated, production by central Pennsylvania coal mines will total 43,500,671 tons in 1925, which is four million tons more than in 1924. The year started off well and then fell into a slump, with production reviving following the strike of miners in the anthracite field, which was largely responsible for the increased production. Approximately 60 per cent of the total production was in mines working on a non-union basis, or under the 1917 scale. The remainder was produced from mines under the Jacksonville agreement.

Prices, except on coke, remain the same from week to week. Coke shows a little increase, egg sizes being quoted at $7.50@$8; run-of-ovens, $6.50@$7; lump coal, $3.50@$4; egg, $4.50@$5; nut, $4.25@$4.75; mine-run, pool 1, $2.75@$2.95; pool 71, $2.50@$2.75; pool 9, $2.35@$2.50; pool 10, $2.20@$2.35; pool 11, $1.70@$2; pool 1, $1.60@$1.70.

At Buffalo the whole trade is so completely at the bottom that even an effort to vary the regular bituminous quotations has been useless. Just now there is a scarcity of slack, but nobody is getting much, if any, more for it, and the chances are that the mine-run output will take up any real shortage in that line. Quotations are $1.60@$1.75 for Fairmont lump, $1.40@$1.50 for mine-run, $1.25@$1.40 for slack; $2.25@$2.50 for Youghiogheny gas lump, $2@$2.25 for Pittsburgh and No. 8 steam lump, $1.30@$1.60 for all slack; $1.75@$2 for Allegheny Valley mine-run; $6.50@$6.75 for Cambria County smokeless; $12 for egg coke, at the curb.

### Dullness Lifts Slightly in New England

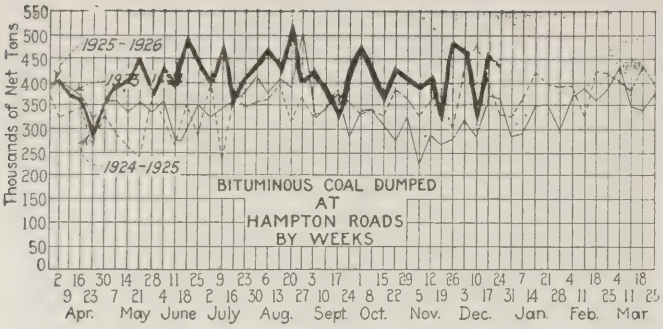
With more seasonable weather the demand for steam coal is somewhat improved in New England. Retailers are again mildly interested in the spot market and transient business in general is noticeably less dull than a week ago. Curtailed production in the smokeless districts has reduced the volume at and en route to Hampton Roads piers, while shipments on contract have increased sufficiently to influence current prices to a moderate degree. In no direction is there brisk inquiry; even for prepared Pocahontas and New River there is only lukewarm request. As a whole, however, the market is in a more hopeful situation than since early November.

A few outlying communities are taking on bituminous and coke in anticipation of running out of anthracite by the end of January, but the aggregate tonnage is not large and there is little to build on in such quarters. If hard-coal mining is resumed by Jan. 15 there will still be a reasonably good demand for substitutes, but the trend will be away from them in favor of anthracite as soon as the latter can be had. The January market will depend somewhat on the volume the hard-coal shippers are able to pour into this territory. For industrial uses there will be no sharp request; the high rate of production since Oct. 1 has anticipated anything like emergency needs during the next 30 to 60 days, and after the holiday season the trade expects only ordinary business. Doubtless steps will be taken to prevent ruinously low prices for high-grade coals.

At Hampton Roads spot coal of No. 1 grade may be had at $5 or slightly less f.o.b. vessel, and at Boston, Providence and Portland on cars the accepted figure per gross ton is $6.50. Moderate congestion at the railroad wharves is in part responsible for this firmer tendency, although more and more household users are turning to mine-run rather than to lump and egg as a substitute for anthracite.

All-rail from central Pennsylvania there is only fair demand for steam coal, and then only for the more favorably known grades. For screened egg of navy standard quality, $5@$5.25 seems to be obtainable, while run-of-mine is quoted at $2.25@$2.50.

Pocahontas and New River prepared coal is being offered all-rail at a wide range of prices. On the same day the trade is offered lump and egg from one operation at $4, from another source a $3 price is named. The aggregate



tonnage of smokeless coals coming all-rail to this market is by no means heavy.

### Steady Movement of Mine-Run at New York

Mine-run bituminous coal continues to move steadily in the New York market, prices remaining firm and practically unchanged. Prepared sizes from central Pennsylvania were in fair call last week, while egg and nut sizes of Pocahontas and New River were in better demand than during the previous few weeks. Nut fared better than egg, being quoted at $4.25@$4.75 as against $4@$4.50 for the larger size.

Short running time at the mines during the holidays is not expected to alter the situation in the trade. There is sufficient coal on tracks to take care of any rush of orders without causing any undue excitement.

Shippers of Southern coals into this market look for increased buying of those coals after Jan. 1, when the new freight tariff affecting the New York and New Jersey markets goes into effect. The new rate averages about $1.10 above the present Clearfield rate of $3.09 to this market.

An end-of-the-year quietness seems to have overtaken the Philadelphia market, but at the first of the year buying should begin with renewed vigor. Despite the quietness of the market spot prices continue fairly stable. For one thing there is no "distress" coal hanging around. There is a little talk about contracts for the first of the year, but with only a small amount of such business closed thus far.

With the strong pick-up in the coke trade there has been a much better inquiry for sized bituminous fields. Slack has been somewhat scarce during the past ten days, due to the falling off in the call for three-quarters and sized coal. However, it would not be surprising to see a considerable increase in slack with the better demand for sized fuel.

The Christmas lull brought no special regrets this year to the soft-coal trade at Baltimore. There is ample coal at tide and awheel between the mines and this point to take care of all needs promptly and, with the exception of a two-weeks flurry in prepared sizes immediately after the onset of the anthracite strike, prices have not varied more than 10 to 15c. f.o.b. mine since Sept. 1. This is undoubtedly due to the moderate home call, despite the use of bituminous as a substitute for anthracite in the East and because of the slump in the export trade. During the past week mines No. 1 and 12 of Consolidation Coal Co. were reopened and in the Georges Creek region of western Maryland there has been an improvement in production, the November figures being 20,000 tons in excess of those of October.

The commercial market at Birmingham has eased up noticeably in the past week or so, inquiry having fallen off materially and the clamor for deliveries having become less insistent. Movement has been exceptionally heavy for several weeks and it is presumed that all large consuming interests are comfortably well fixed on reserves. The mines are in no immediate need of bookings on which to operate after the holidays, and opinion in the trade is that prospects for the first quarter are satisfactory as far as steam coal is concerned. Buying for bunkers has not abated, though it is not quite as active as it has been, and inquiries are still coming in for extra tonnage.

The lull in the domestic market is more pronounced than in the steam trade. Little new business is being taken on at present, as weather conditions have been unfavorable. A light snow followed by lower temperatures late in the week will no doubt stimulate buying temporarily if the cold spell is of sufficient duration, as stocks in the hands of dealers and consumers are light.

Quotations have undergone no change the last week and seem fairly well entrenched against decline in the near future.

Inquiry from northern and western points for coke has improved in the past week, and demand continues good in local territory. Foundry ranges $6@$6.50, gas-house, $6@$6.50, and egg and nut, $4.75@$5.50 per ton ovens.

Coal output in the week ended Dec. 12, which reached 450,000 tons as reported to the Alabama Mining Institute, broke the record of this field for a similar period with the possible exception of one week in 1923, on which the records are not exactly clear.

### Hard-Coal Substitutes Stiffen

Lower temperatures in New York last week strengthened the demand for anthracite substitutes, coke heading the list with better prices. Some manufacturers are said to be refusing orders because they are sold up. Beehive coke is quoted at $8.25@$8.75. Most retail dealers are awaiting continued colder weather before increasing their buying orders, as consumers are unwilling to put in large tonnages of substitutes in view of the various efforts being made to bring the strike to an end.

Nothing but No. 1 buckwheat in the hard-coal list is to be found in the harbor and most of it is not of very good quality, according to the dealers. Quotations range from $9 to $10 alongside, with a comparatively small tonnage offered. Arrivals of British anthracite have not been heavy.

At Philadelphia a strong buying market is once more developing in coke, and many shippers of this fuel are sold up for weeks ahead, and this includes byproduct and beehive, although there is still a fair offering of the latter to be had, but mostly merely crushed and unsized. Anthracite steam coal users while they have received the last of the company storage coal, have not as yet shown any inclination to buy bituminous coal to eke out their supplies, but this seems certain not to be postponed much longer.

While Baltimore anthracite dealers are watching developments in that field with interest, they are pushing the sale of substitutes for hard coal. There is a wide difference of opinion among dealers as to how much of the trade will be regained by the hard-coal interests.

Activity continues in the coke trade at Buffalo, though it has not become as pronounced as was expected. Probably the many reports of an early settlement of the strike have kept people from buying coke to a considerable extent. They want to buy anthracite or they look for coke to be cheaper as soon as the strike is settled, no matter if new-mined anthracite is slow in appearing. The most favorable state of the trade is that coke prices, the real standby in an emergency, have not gone up lately, as was considered likely.

### Connellsville Coke Market Firmer

No sooner had most of the uncovered blast furnaces made first-quarter contracts on the recent softening in the coke market (at $3.75 to $4 as reported, but is seems one or two contracts were at under $3.75) than the spot market became very active, partly because of blast furnaces buying extra lots to insure supplies over the holidays but largely by reason of much more Eastern buying.

Yard crushed coke, which had sold at down to $4.25 and then had brought up to $6, has now touched $8, and better prepared coke probably has gone up to $9. The best preparations are hardly obtainable at all.

Regular run-of-oven blast-furnace coke, which a week ago was reportable as advanced from $3.50 to $4, has since gone up to $6, at which there have been bids in the past few days. While blast-furnace interests purchased freely at the lower prices, at least two belated buyers came in last week, paying $5.25 and $5.75 respectively.

Most of about 600 cars loaded on track without destination a short time ago was taken up without much advance in price, and then operators began stiffening sharply in their quotations, getting the advances without difficulty. By this time substantially all the accumulation is taken up, while production is faced with a decrease. Supplies of coke in the East are now quite well worked off and it seems there has to be buying in proportion to the consumption.

# Foreign Market And Export News

## Bookings and Inquiry Brisk in British Market; Work at Mines Steadier

The British coal market continues steady with traces of firmness in several departments. Collieries are receiving a moderate amount of inquiry over the early part of January. Pits are working more regularly than for several months. The South Wales output has improved to nearly 900,000 tons a week, and prospects are held out of a million-ton level being attained over the next few weeks. French demand is still disappointing, though inquiry tends to expand for later delivery; Italian orders are fairly numerous, and South America is now taking heavy deliveries. Coaling depots are quieter, but there is a moderate movement to the United States, Spain and Portugal.

The prompt market has been much firmer at Newcastle-on-Tyne, thanks to more tonnage being available, and quotations are again more in accordance with actual business. For forward delivery there is quite a healthy demand, but the actual transactions are not so good, as sellers are holding firmly for the current quotations into January. The coke sections, after a slight period of depression, have firmed up wonderfully well, and cargoes are being ordered for the United States as well as for the Continent. This, in conjunction with a better tone in the iron and steel trade, is having a stimulating effect upon coking coals. Gas coals are firm and steady for six weeks ahead. Steams are rather erratic.

Output by British collieries during the week ended Dec. 12, according to a special cable to *Coal Age*, totaled 5,430,000 gross tons, compared with a production of 5,210,000 tons in the preceding week.

## Trade Softens All Round At Hampton Roads

Hampton Roads business last week was dull, with prices weakening, and the general holiday laxity falling on the trade. Movement in all directions was comparatively small, and there was a likelihood of continued dullness for two weeks.

Many mines serving this section already have agreed to shut down until Jan. 4, but many factories promise to do the same thing, so the net result is not expected to be a strengthening of the market to any appreciable extent. Shippers reported good surpluses at the mines, and that they expected comparatively light trade until the second week of the new year.

## Stronger Industrial Demand In Belgian Market

A very slight improvement in demand for industrial coals has appeared in the Belgian market. This is due to a partial suspension of imports of German fuels and to fears of a general strike if no agreement on the wages of Belgian miners is possible. In the Borinage, coals are still being stocked, but in the other fields there is a slightly better demand.

Sales of house coals, notwithstanding the cold and snowy weather, however, seem to be less active than they were a month ago. This is mostly due to the fact that, since the Belgian coal owners exacted from their French customers payments in Belgian francs instead of French francs, as heretofore, the demand from France for Belgian household fuels has receded.

## Industrial and Domestic Trade Active in French Market

The collieries of the Nord and Pas-de-Calais, in France, are particularly busy; their output of industrial grades is well sold and for household coals their market continues to be marked by the greatest activity.

Since the prices for the sale of Belgian coals in France have been adjusted to take into account the depreciation of French currency compared to the Belgian franc quotations are based on an exchange rate of 100 French francs to 83.15 Belgian francs, with a variation of a few centimes among the various collieries.

Arrivals of empty trucks at the collieries have been more regular of late. Canal freight rates are still high, being quoted on the basis of 28 fr. Bethune-Paris.

Deliveries of indemnity coke from the Ruhr to the O. R. C. A. during the first eight days of December totaled 69,712 tons, or a daily average of 8,090 tons.

The prices of anthracite sized coals delivered by Germany on reparation account have been raised by 10 fr. per ton—the nuts to 220@235 fr., the cobbles to 215@230 fr., according to grade and destinations. The increase went into effect Dec. 16.

# News Items From Field and Trade

## ALABAMA

The Gulf States Steel Co., of Birmingham, is reported to have acquired 36,000 acres of coal land in Tuscaloosa County, near Gadsden, which it will develop.

## ILLINOIS

A. E. Lewis, of Worden, has been elected Madison County mine inspector for another year. The Board of County Supervisors voted unanimously for Lewis' retention in his post. No other application for the job was received.

The Black Star Coal Co. resumed work early in December at its mine at Logan, in the vicinity of Benton, after an idleness of several months.

William Haywood, top foreman at the Indiana & Illinois Coal Corporation's mine No. 10, Nokomis, has been appointed Assistant Director of Mines and Minerals of Illinois. Mr. Haywood was for a number of years assistant general superintendent of the Indiana & Illinois corporation mines near Nokomis.

## INDIANA

American No. 1 mine near Bicknell has resumed operations. It has been down since Nov. 20 when thirty trip riders and motormen went on strike unauthorized by the United Mine Workers. The strike forced 500 other men to quit work. The trouble was caused by the refusal of the mine boss to return one trip rider to work after the man had threatened the boss's life with a revolver in a dispute over working conditions.

The Patoka Coal Co. will begin operations on the Harris lease near Petersburg soon. The company has purchased a railroad locomotive and other equipment to aid in moving the mined coal to spur lines.

A suit involving $7,000,000 worth of coal was filed in Pike County Circuit Court at Petersburg, Dec. 17, by the Mercantile Commercial Bank of Evansville, receiver of the Vulcan Coal Co. The suit asks that property that formerly belonged to the Vulcan company he returned to the receiver, that the transfers made from the Vulcan company to the Southwestern Indiana Coal Corp. be set aside and that the contract between the corporation and the Enos Coal Co. be annulled. Former stockholders of the Vulcan company allege that the transfer of property from that company to the Southwestern Indiana corporation was irregular. Property involved includes some of the most valuable coal stripping lands in southwestern Indiana.

A new production record for one week for southern Indiana shaft mines was set by Francisco Mine No. 2, near Princeton, in the week ended Dec. 19, when 12,487 tons of coal was hoisted, an average of 2,081 tons per day. The coal was loaded into 232 railroad cars. The mine now employs 350 men and has a monthly payroll of $60,000.

## IOWA

Peace reigns again between members of the Des Moines local of the United Mine Workers, district No. 13, and the executive board of the district following a fortnight of what several Des Moines miners characterized as "enmity." Members of the district gave a vote of confidence to their officials after several hours' discussion of the agreement between the Hartford mine management and themselves.

A 7-ft. seam of high-grade coal recently was discovered near Odebolt while drilling a test oil well. The coal was found at a depth of 498 ft. under 27 ft. of cap rock and 12 ft. of shale.

## KANSAS

The Black Diamond Coal Co., of Pittsburg, has applied for a Kansas charter. The capitalization is $10,000. The incorporators are H. J. Feiden, R. D. Wilson, Walter Bennett and William Whetstone, all of Pittsburg. They recently opened a small deep mine two miles east of Pittsburg and have purchased an additional lease for sinking another mine.

Ira Clemens, one of the leading coal operators of the southeastern Kansas field prophesied in an address before the United Commercial Travelers at Pittsburg recently that within less than a half century coal will be pulverized at the mines near Pittsburg and blown to Kansas City through pipe lines for fuel for steel mills and other industrial plants. Small electric generating plants to burn Kansas coal will dot the field, he believes. With new methods close to 100 per cent of the coal in a working will be brought out instead of the present average of 65 per cent.

Unofficial figures, but obtained from authoritative sources, indicate that Kansas coal production for 1925 will run close to 6,000,000 tons, the largest since 1920. In addition to these figures a "statistics hound" has found that since 1884, the first year in which output reached 1,000,000 tons, the Kansas field has marketed 182,600,914 tons of coal, exclusive of the current year. The first official record of coal production was in 1869, when the output was 36,891 tons. The production peak was reached during the World War, when 7,250,000 tons was mined in 1917 and again in 1918. In 1919, 5,400,312 tons was produced; 1920, 6,130,341 tons; 1921, 4,028,624 tons; 1922, 3,518,243 tons; 1923, 4,650,478 tons; 1924, 4,491,069 tons.

## KENTUCKY

On Christmas eve James Hatcher, of the James Hatcher Coal Co. at Big Shoal, five miles below Pikeville, presented to each of his 400 miners a box of candy.

The Red Star Coal Co., Whitesburg, has leased 50 acres of land and will develop it.

The West Kentucky Coal Co., Sturgis, a subsidiary of the North American Co., expects in the near future to construct a power transmission line approximately 40 miles long, to join its Earlington power plant with the Sturgis power plant.

## MINNESOTA

The city ordinance of Minneapolis forbids the use of other than smokeless coal in railroad locomotives, but it has seldom been enforced in any degree. Now it is proposed to amend the ordinance to permit the use of other grades, but with time limits as to the extent and amount of dense smoke. Railroad men have insisted that they could not use smokeless in locomotives.

## NORTH DAKOTA

Records on North Dakota lignite shipments filed with the state railroad board of that state, show a growing market for it. In the week ending Oct. 24, 1924, 26,647 tons was shipped within the state and 2,854 tons shipped outside the state. For the corresponding week of 1925 the shipments within the state had grown to 43,155 tons and the outside shipments to 4,308 tons.

## OHIO

More of a feeling of optimism pervades the coal field of Jefferson County in view of recent developments, after a period of about 18 months' idleness. The large mines of the United States Coal Co. at Plum Run and Bradley have resumed operations with reasonable expectation that they will be operating at capacity before long. Improvement is in evidence also at the mines of the Jefferson Coal Co. at Piney Fork. The Y. & O. mine at Glen Robbins is operating once again, as is the Clarkson mine at Dunglen. The Hanna mines at Dunglen are in operation once again and the New Pittsburgh mines at Ramsey and Rhodesdale are increasing their output. It is noticeable that the deep mining operations are improving to a greater extent than the stripping.

Nine men died in the Webb mine of the Cambria Collieries Co. the night of Dec. 22 after a rock fall had brought down a feeder line, causing a short-circuit that ignited a body of gas. Two more men were overcome and rushed to a hospital at Bellaire. Fire followed the blast. Only 79 men were in the mine at the time.

Improvements which will greatly increase output are now under way at the stripping mines which the Harmeyford Coal Co. recently purchased from the Kehota Mining Co. in the heart of the Hocking Valley. A new tipple and track will be put in at Baird's Furnace, New Straitsville, and when they are completed a million tons of 10-ft. coal will be opened up. The other mines are the Saltillo plant, near Redfield, and the McCuneville mine, near Shawnee. The Harmeyford company was formed when the organization took over the Kethota property. The name is coined from the names of the officers of the company: William S. Harman, of Columbus, president; John Winefordner, Zanesville, vice-president, and E. R. Meyer, of Zanesville, secretary-treasurer. The field operations are under the direction of Mr. Winefordner. The company has an acreage of 2,500, the property being worth $1,500,000. The output is now 2,000 tons a day.

## PENNSYLVANIA

After a meeting of the board of directors of the Lehigh Valley Coal Co. on Dec. 22 it was announced that the regular dividend of the company had been declared. An initial dividend of $1.25 was declared a year ago and another of $1.25 was declared last June, presumably placing the stock on a $2.50 annual basis.

The Snowdon Coke Co., of Pittsburgh, has contracted with the Marion Machine, Foundry & Supply Co., of Scottdale, for the erection of a coke crushing and screening plant for the sizing and preparation of coke. Heretofore this company has not shipped any coal or prepared sizes of coke, confining its activities to the production of furnace and foundry coke.

Coke having taken a new lease of life, the H. C. Frick Coke Co. has fired up the Davidson plant, with 200 ovens, which had been idle for the last two years. The Franklin Coke Co. has resumed operations at its 30-oven plant at Tippecanoe, after several weeks' idleness. The Stern Coal & Coke Co., which banked its 132 ovens a few weeks ago, also has resumed.

C. E. Cowan, of Greensburg, chief engineer of the Jamison Coal & Coke Co., has been appointed consulting engineer of new construction work by the Snowdon Coke Co. at its Mt. Hope plant, at Linn, near Brownsville.

More than 100 men interested in industry in the Monongahela River district, including coal companies and steel concerns, were present at a hearing before the U. S. Engineer at Pittsburgh Dec. 23, in an effort to persuade the engineer not to recommend the abandonment of the proposed canalization project in the Youghiogheny River. The movement to keep the canalization project a live issue was started by the Pittsburgh Coal Co., which has large coal deposits along the Youghiogheny.

The Pittsburgh Coal Co. last week evicted ten families from their houses at the Montour No. 10 mine, at Library. The statement of the company said the men were indebted for six months' rent and that the houses were needed for men who were at work.

The Rich Hill mine of the McClane Mining Co., at Canonsburg, is operating with about 25 per cent of its 450 men at work under the Jacksonville agreement, according to a statement by W. H. McClane. The company is only having some cleaning up done and some coal recovered that would otherwise be lost. Future operation, it was said, would depend on market development and other things.

After serving for 65 years in various capacities in the anthracite mining industry, John Harvey, of Hazelton, recently stepped down as a member of the Taxpayers Association of Hazelton. The association is composed of anthracite mining companies and for years has been administering the road taxes in Hazelton, Foster and Banks Township. Mr. Harvey started as a breaker boy in the mines of the Hazelton field and for 29 years was superintendent of the Coleraine mine. John Crooks, superintendent of the Lattimer mines, has been named to succeed Mr. Harvey as president of the association; A. B. Jessup, of the Jeddo-Highland Coal Co., has been named vice-president, and Scott Young, real estate agent for the Lehigh Valley Coal Co., will continue as secretary of the organization.

Two hundred miners employed at the mines of the Superior Coal Co. near Cheswick went back to work last week with the reopening of the mine, which was closed two weeks as a result of a cave-in in the shaft.

Pittsburgh and western Pennsylvania labor organizations will be assessed a portion of their wages on Jan. 7 to assist the striking anthracite and bituminous miners of Pennsylvania, it has been announced by P. T. Fagan, president of District No. 5, United Mine Workers. This is a result of the action taken by the American Federation of Labor, when William Green, president, made an appeal for funds.

Approximately 70,000 1-lb. boxes of candy were distributed during Christmas week by the Union Supply Co. at the mining plants of the H. C. Frick Coke Co. A "treat" to children of employees was given generally on Thursday.

**A Mine Fan House Down in New Mexico**

A part of the ventilation plant at Mine No. 6 of the Phelps-Dodge Corp., located at Dawson, N. M. This housing represents a high type of construction by a company which pays particular attention to its ventilation problems.

## WASHINGTON

Five underground men were killed and several overcome by carbon monoxide following a dust explosion in the Wilkeson Coal & Coke Co. mine in Wilkeson, Dec. 14. The explosion followed a shot to dislodge a boulder that had choked a steeply pitching chute. The report of Chief Mine Inspector William Reese shows that Assistant Foreman C. E. Farrell, who helped place the stick of dynamite on top of the boulder and mud it in according to the prevailing custom in "bulldozing" rocks, had tested for gas and found none before he lit the fuse and retreated. However, an explosion swept through part of the mine. There were evidences of coal dust in the section and Mr. Reese attributes the spread of the blast to that, although "the floors and walls of the crosscuts showed dampness and moisture, and, particularly in one crosscut, pools of water lay on the floor."

## WEST VIRGINIA

Dakota mine No. 41 of the Bethlehem Mines Corp. loaded 1,984 net tons of coal Dec. 22, a new record for 110 men employed at the plant.

"The Coal Smellers," an organization of officials of the J. H. Weaver coal interests in West Virginia, and their guests attended a banquet at the Waldo Hotel in Clarksburg, Dec. 19. More than forty-five employees of the Weaver mines in West Virginia—at Dawson, Rose Hill and Ironia—were present. James A. Jenkins, general superintendent, was the guest of honor, and F. M. McDaniel, of Clarksburg, was toastmaster. Among those who spoke at the banquet were Charles B. Johnson, Dr. H. A. Rosenthal and Dr. W. A. Thomason, of Clarksburg; Ralph H. Ely of Buchannon; E. D. Lyle of the New York Central R.R., R. E. Rankin, W. H. Schmeltzer and A. M. Grase of Pittsburgh, Pa., representing the Goodman Manufacturing Co., and G. L. Pettrey and Frank Haller of the Clarksburg Candy Co.

On Dec. 22 Governor Howard M. Gore of West Virginia announced the reappointment of Robert M. Lambie as chief of the state department of mines of West Virginia for the term of four years beginning Jan. 1. Mr. Lambie became head of the department of mines Feb. 14, 1920. He was appointed by former Governor John J. Cornwell to succeed W. J. Heatherman. The legislature early this year increased his salary from $5,000 to $6,000.

The Lanark Fuel Co., having equipped its mine with a new tipple and outdoor conveyor system, resumed operations on Monday, Dec. 21, after several months' inactivity. The company's tipple burned last March. Production is expected to reach 300 tons a day. Coal will be mined not only in the Sewell vein but in the Beckley seam as well.

P. J. McGraw, superintendent of Federal mine No. 1, at Grant Town, who recently removed to Fairmont, was presented with a gold watch on Dec. 17 by a number of workers.

On Dec. 19 for the first time in its history, the Baltimore & Ohio R.R. moved a mallet train out of the Fairmont yards over the Connellsville division. Sixty-five cars of coal were moved over the "Sheepskin." Mallet trains are almost exclusively run between Fairmont and the Keyser scales over the Alleghany Mountains, east of Grafton.

The Island Creek Coal Co. has awarded a contract to the Winter Homes Corp. of Huntington for the construction of 165 miners' houses at Holden. This is said to be one of the largest contracts for the construction of miners' dwellings which has been let in the state for several years.

The National Coal Mining Co., of Pittsburgh, Pa., has sold the Pollar mine in Lewis County, between Clarksburg and Weston, near McWhorter, to a company being formed by John P. Whelan, formerly of Cleveland, and at one time general superintendent of the Brady-Warner Coal Corp. plants. There are 1,400 acres of Pittsburgh and Redstone coal in the tract. The mine will be reopened about Jan. 15.

The Whyel Coke Co. with main offices at Uniontown, Pa., has sold Yukon mine, at Arnettsville, Monongalia County, to the Imperial Coal Corp. of New York City, for $1,000,000. The property has 2,000 acres of Pittsburgh coal and the company's present capacity is 1,000 tons a day. The new owners, it is said, will increase their daily capacity to 2,500 tons.

## ALASKA

Candle Creek lignite mine is producing 25,000 tons a year from a seam 88 ft. thick. Healy River Coal Co. has contracted to supply 25,000 tons a year to Fairbanks dredges. The Evan Jones mine, at Matanuska, has contracted for 150 tons a day to the Alaska Ry. Howard-Jensen mine started production in September and is supplying coal to coast points. The Alaska-Pacific Coal Co. has arranged to complete the Katalla Ry. and ship coal to Pacific Coast points.

## CANADA

T. M. Molloy, Commissioner of Labor and Industries for Saskatchewan and a member of the Lignite Board of Canada, has returned from a two months trip to Europe, the object of which was to have Saskatchewan coal tested in various types of carbonizers. He had tests made in three carbonizers in England, three in Germany and one in Czechoslovakia with a view of ascertaining by which method the best results could be obtained. Some of the tests brought out large quantities of tar and others oil. While in England, Mr. Molloy had the hearty co-operation of all British Research officials.

Word has been received at Regina, Sask., that large-scale briquetting tests conducted in Germany last summer with lignite from southeastern Saskatchewan have proved a technical success. Whether or not this means that the German process will be adopted in Canada will not be known until final results are studied. The report has been received by W. D. Worcester, a professor of Saskatchewan University, who was sent to Germany last summer in charge of 52 tons of lignite from the Taylorton district. The tests were conducted by Thyssen and Co. at Malheim-Ruby, and the Lurgi Co. at Frankfort.

# Traffic

### Hearing on Coke Rate Changes

The Coal, Coke & Iron Ore Committee, Central Freight Association territory, will hold a hearing in room 606 Chamber of Commerce Building, Pittsburgh, Pa., Jan. 7, 1926, at 10 a.m., on proposed changes in rates on coke, coke breeze, coke dust and coke screenings (the direct products of coal) from Ashland, Ky.; New Boston, Portsmouth and Ironton, Ohio, to stations in Michigan. The changes cover advances and reductions to bring about a proper relation with rates via all routes and with rates from other districts. Details of the proposed changes will be furnished promptly by the committee upon request.

### Seek Removal of Differential Against Ohio

The state of Ohio will join the Ohio coal operators in asking the Interstate Commerce Commission to reconsider its decision sustaining a differential freight rate schedule, favoring West Virginia and Kentucky over Ohio mining operations. An announcement to this effect recently was made by Attorney General C. C. Crabbe of Ohio. H. H. Griswold, First Assistant Attorney General, and John W. Bricker, special counsel in the office of the Attorney General, will act as special counsel in the case. The Attorney General's announcement was made following a conference with D. F. Hurd, Cleveland, and E. S. Ballard, Chicago, counsel for the Pittsburgh Vein Operators' Association of Ohio.

The Kalbaugh Coal Co., of Cumberland, Md., has made application to the Interstate Commerce Commission to have its rate on eastern coal shipments reduced. The concern operates a mine at Barnum, near Piedmont, Mineral County, W. Va., and it asks the commission for a lower rate than the mines further west, because the Baltimore, & Ohio R.R. does not have the expense of hauling its product over the Alleghany Mountains. At present all the mines of the Preston County fields, which include Tunnelton and other sections have the so-called Myersdale rate, which is 25c. less than the Fairmont rate. An Interstate Commerce Commission examiner will hear the application in Cumberland, Md., on Feb. 4.

# Obituary

**James R. Thomas**, 65, president of the Carbon Fuel Co., Cincinnati, Ohio, died Dec. 27 at his home in Charleston, W. Va. He was widely known in coal circles in Cincinnati, where he was a member of the Queen City Club and other organizations. In the late eighties he became purchasing agent for the Mt. Carbon Coal Co. and acquired holdings on Cabin Creek, which later were to be the scene of much coal activity. About twenty-five years ago he, with A. E. Humphries planned and built the long spur of railway line up Cabin Creek, which was connected with the Chesapeake & Ohio lines at Leeward. Through this Mr. Thomas was able to open and develop the coal lands which he owned on Cabin Creek. In order to market the product of this and other mining properties in the Kanawha fields the Kanawha Coal Co. was organized with main offices at Cincinnati. This selling organization was maintained until about twenty years ago, when Mr. Thomas established the Carbon Fuel Co.

**Andrew Cattanach,** for 35 years connected with the coal trade in the Twin Cities, died recently at his home in Minneapolis, Minn., aged 65 years. He was first connected with the C. G. Lewis Coal Co. in St. Paul. The business was afterward purchased by the Philadelphia & Reading Coal & Iron Co. and he remained with that company in varying capacities for a number of years. About five years ago he was made cashier of the Minneapolis office. The widow, a brother and three sisters survive.

## Coming Meetings

**Chicago Wholesale Coal Shippers' Association.** Annual meeting, Great Northern Hotel, Chicago, Ill., Jan. 6, 1926. Secretary, G. H. Merryweather, Temple Bldg., Chicago, Ill.

**American Wood Preservers' Association.** Annual meeting, Jan. 26-28, 1926, at Cleveland, Ohio. Secretary, E. J. Stocking, Chicago, Ill.

**Coal Club of Philadelphia.** Annual meeting, Jan. 28, 1926, at the Bellevue-Stratford Hotel, Philadelphia, Pa. Secretary, C. K. Scull, Philadelphia, Pa.

**Northeast Kentucky Coal Association.** Annual meeting, Jan. 28, 1926, at Ventura Hotel, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

**American Institute of Electrical Engineers.** Annual convention, Feb. 8-12, 1926, at Engineering Societies Bldg., New York City. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

**American Institute of Mining and Metallurgical Engineers.** Annual meeting, Feb. 15-17, 1926, at Engineering Societies' Building, New York City. Secretary, Dr. H. Foster Bain, 29 West 39th St., New York.

**The Rocky Mountain Mining Institute.** Winter meeting, Feb. 23-25, 1926, at Albany Hotel, Denver, Colo. Secretary, Benedict Shubart, Boston Building, Denver, Colo.

## New Companies

**The Cedar Coal Co.** was incorporated in Canon City, Colo., early this month, with a capital stock of $20,000, by B. M. Narron, Wm. Starret and P. Westwater.

**The Widwest Coal Co.** was incorporated in Colorado the first week in December, with a capital of $25,000, by S. W. Ackerman, of Grand Junction, and J. S. Chayney, N. Richards and D. Moschetti, of Palisades.

**The Westerik & Folkerts Coal Co.** was incorporated in Denver, Colo., the first part of December, with a capital of 50,000 shares of no par value by G. J. B. Westerik, P. S. Van Cise and others.

**The A. W. Hall Coal & Oil Co.** was incorporated in Denver, Colo., early in December, with a capital stock of 500 shares of no par value, by A. M. McNeil, F. A. Wachob and A. W. Hall.

**The Copen Creek Coal Mines, Inc.,** has been organized with a capital of $10,000 to operate at Copen, in the Braxton County field of West Virginia. Chiefly interested in the new concern are C. W. Flesher, Mary E. Flesher, Lucille Flesher, all of Gassaway, and J. K. Favison and J. K. Tosh, of Bower, W. Va.

## Association Activities

The annual meeting of the **Hazard Coal Operators' Exchange** will be held at Lexington, Ky., on Jan. 22, with a business meeting in the daytime and a banquet in the evening.

The annual meeting of the **New River Coal Operators Association,** held at Mount Hope, W. Va., Dec. 17, was attended by more than 100 operators. The officers' reports showed the organization in a flourishing condition. M. L. Garvey, general manager, Maryland-New River Coal Co., Winona, W. Va., was elected president; William McKell, vice-president; P. M. Snyder, treasurer, and S. C. Higgins, secretary and traffic manager. The executive committee chosen was as follows: G. H. Caperton, president of the New River Coal Co., Charleston; S. A. Scott, vice-president, New River Coal Co., MacDonald, W. Va.; William McKell, president, McKell Coal & Coke Co., Glen Jean, W. Va.; Ernest Chilson, vice-president and general manager, Raleigh Coal & Coke Co., Raleigh, W. Va.; R. E. Taggart, vice-president, Stonega Coke & Coal Co., Big Stone Gap, Va.; P. M. Snyder, president, Long Branch Coal Co., Mount Hope, and President Garvey. A general discussion of roads followed, during which it was decided that a large delegation representing the association—which in turn represents the heaviest tax payers in that section of the state—should wait upon the road commission with a definite plan of suggestions regarding the designation and building of much needed public highways for the whole southeastern part of West Virginia.

# New Equipment

## Combined Hanger Increases Circuit Efficiency

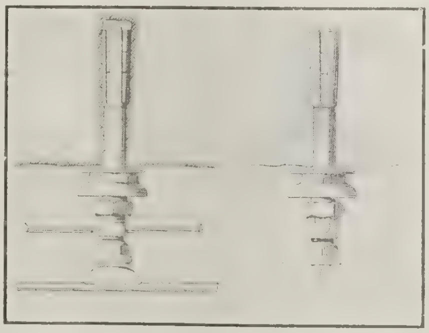
Necessity, justly famed as the mother of invention, not infrequently proves herself the grandmother of economy. Such was the case with the combined trolley and feeder-cable hanger shown in the accompanying illustration, which is the invention of C. E. Rogers, chief electrician of the Logan division of the West Virginia Coal & Coke Co., and which is being placed on the market by the Guyan Machine Shops.

Carrying the feeder cable along the side of the entry and joining it to the trolley outlet at considerable intervals introduces many disadvantageous features. Thus an appreciable difference may exist between the potentials of the wire and feeder while a jumping trolley may break the connection between the two. A side feeder also entails a separate line of supports and insulators with their necessary expense of insulation and upkeep.

In this new hanger the lower part or element is similar to that of the ordinary type being fitted with the usual jaws to grip the grooved trolley wire. The upper end of this element, however, is split or forked to receive the feeder. This is here inserted and the tightening of the nut binds the feeder in place and bonds it electrically to the trolley. The size of the feeder employed may range anywhere from a 4/0 wire to a 500,000-circ.mil cable. Either, or any intermediate size can be held securely.

### Lowers Costs, Increases Safety

By the use of a hanger such as this only one line of insulators and supports is used in a heading, the cost both of installation and upkeep being proportionately decreased. There is no danger of the connection between feeder and trolley wire being broken by contact with a "wild" trolley wheel or pole. Furthermore, the feeder and trolley are connected at frequent intervals assuring that both will be at practically the same potential at all points along their course.



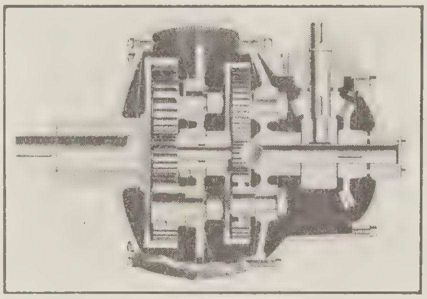
**Side and End Views of Hanger**

This device is practically an ordinary trolley hanger with added provision for supporting a feeder cable above it. The arrangement is such that a line of these hangers may be put in place without taking down or even seriously disturbing the trolley. If either trolley or feeder line becomes slack through stretching or otherwise they may be tightened both quickly and easily.

Most locomotive drivers blame the return for all the ills of low voltage. As a matter of fact the positive side of the circuit in many instances is quite as truly responsible for the low potential at the point where electrical energy is applied as is the negative. It is just as important, therefore, to reduce the losses in the trolley and feeder lines as in the rails. Efficiently copper-bonding the rails is not in itself enough to prevent severe electrical losses with their attendant evils. Over six miles of this kind of electrical construction has been installed during the past few months and is giving excellent satisfaction.

## New Right-Angle Drive Spur Reducers Save Space

In order to effect space economies impossible with straight-line motor drives, especially for installations where the driven machine is crowded against a wall or into a corner, Foote Bros. Gear & Machine Co. has brought out a new line of IXL right-angle drive spur reducers.



**It Is a Compact Unit**

This cut-away view of the new speed reducer shows the arrangement of gears and shafts—especially the bevel pinions at the high speed end—which permit of right-angle drive for tight corners where there is no space for straight-line mounting of the motor.

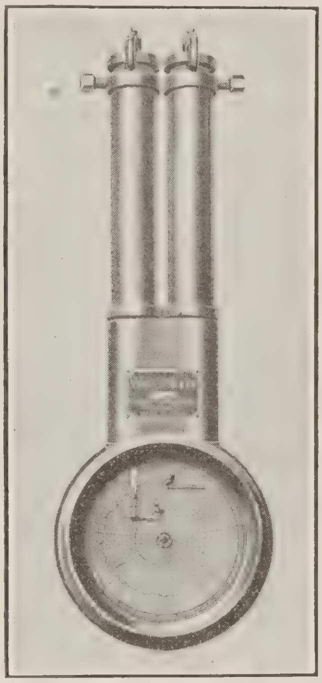
The new unit is similar in exterior appearance to the company's standard straight-line drive speed reducers, except that the high speed and low speed shafts project through the case at right angles to each other. This change in direction is accomplished by means of bevel or mitre gears mounted in the high speed end of the unit. A secondary bevel or mitre gear is mounted on the high speed driving shaft which is concentric with the low speed shaft.

The high speed pinion is integral with the high speed shaft and delivers the power through three idler gears set at 120-deg. angles to a large rotating integral gear. The internal gear is securely fastened to the slow speed shaft. The high speed pinion, together with the idlers, internal gear and slow speed shaft comprise the entire mechanism for a single reduction train which can be repeated in obtaining greater reduction ratios.

By changing the size of the pinion and internal gear and the relative size of the bevel gears in the high speed end, almost any desired relation may be obtained between the speeds of the two shafts. The manufacturers produce these right angle spur reducers in a large variety of standard sizes and reduction ratios, horsepowers ranging up to 150-hp. and reduction ratios up to 350 to 1.

## Waste Meter Continuously Indicates Boiler Losses

In any boiler plant the greatest loss sustained is that of the hot gases going up the stack. In order to measure accurately this loss the Uehling Instrument Co., of Paterson, N. J., recently has placed on the market a recording instrument known as a waste meter and shown in the accompanying illustration. This records both the temperature of the escaping flue gas and its content of carbon dioxide on the same chart. The corresponding loss may be read from a table furnished by the manufacturer.



**Shows Heat Losses**

This little instrument continuously indicates both the temperature of the flue gases and their content of carbon dioxide. A constant visual index is thus afforded the fireman of the conditions existing within the furnace.

Reduction of chimney losses involves both a decrease in temperature and an increase in the content of carbon dioxide of the products of combustion. With the aid of an instrument of this kind it is an easy matter for the fireman to control the air supply and to make the stack loss a minimum. This instrument embodies both a pyrometer and a gas analysis element.

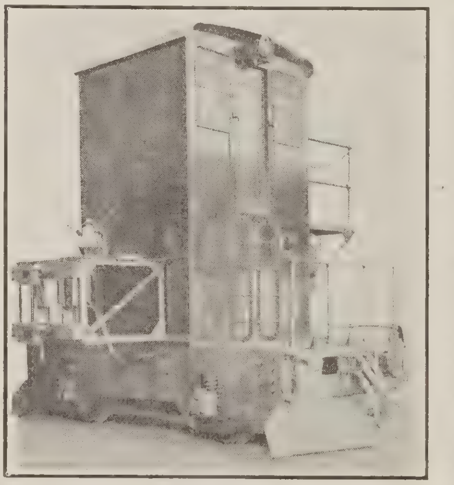
The pyrometric element works on the principle that any change in temperature of the flue gases will make a corresponding difference in the pressure of vacuum existing in a chamber into which flue gases at constant temperature and at actual stack temperature pour through two orifices under the action of a constant suction.

The gas analysis element is similar to that recording temperatures except that the gas is passed through a dry cartridge that absorbs the carbon dioxide. By these means two pens are actuated upon a single circular chart and both the temperatures and carbon dioxide content of the flue gases continuously recorded. Careful manipulation of the drafts is particularly necessary during peak load periods because at that time losses both from temperature and excess air are likely to be most severe. Visual indication of conditions existing in the furnace and boiler, made possible by the use of this instrument, do much to rectify errors in air supply and increase the overall efficiency of the entire equipment.

## High Locomotive Facilitates Coke Quenching

In the accompanying illustration may be seen a new type of locomotive recently placed on the market by the General Electric Co., of Schenectady, N. Y. This machine is intended for handling quenching cars in byproduct coke yards, particularly for transporting hot coke from the ovens to the quenching tower.

This locomotive is especially designed to facilitate these operations. A platform on the side enables the driver to leave his inclosed cab for purposes of observation. The cab itself is of the double-deck type and may be lined with asbestos as a protection from the heat of the ovens and coke. The projection or arm on the left side, upon which the bell is mounted, is the third rail collector, the third rail used at coke plants being usually suspended above rather than laid along the ground as in elevated and interurban lines. The locomotive is supplied with air-brake equipment, the pump also being used to supply air to the dumping mechanism on the quenching car.



**High Enough for Good Observation**

On the left is the arm carrying the shoes that collect current from the third rail. A slightly higher platform on the right serves for purposes of observation. The air pump not only furnishes air for the operation of the brakes but for the dumping mechanism on the quenching car as well.

## Publications Received

**The Industrial Museum,** by Charles R. Richards. The Macmillan Co., New York City. Pp. 117; 6 x 9½ in.; illustrated. Price, $3. A plea for the establishment of industrial museums in America. The author describes his trip to the four great European industrial museums in Paris, London, Munich and Vienna.

**Factors Affecting Production of Lump Coal,** by J. E. Tiffany and B. L. Lubelsky. Coal mining Investigations under auspices of Carnegie Institute of Technology, U. S. Bureau of Mines and Advisory Board of Coal Mine Operators and Engineers. Bulletin 19. Pp. 94; 6 x 9 in.; illustrated. Price, $1.

**Mechanical Safeguarads in Rotary Drilling,** by H. C. Miller. Bureau of Mines, Washington, D. C. Technical Paper 369. Pp. 38; 6 x 9 in.; illustrated. Price, 10c.

**Coal-Dust Explosions:** The Effect of Release of Pressure on Their Development, by H. P. Greenwald and R. V. Wheeler. Safety in Mines Research Board, Paper No. 14. H. M. Stationery Office, Kingsway, London, England. Pp. 12; 6 x 9½ in.; illustrated. Price, 3s. net.

**Mechanical World Year Book, 1926.** Emmott & Co., Ltd., Manchester, England. Price, 36c. Pp. 348; 4x6 in.; illustrated. New features introduced in this edition are sections on the Uniflow Engine, Fuel Economizers, Notes on Grinding, etc.

**A Study of Skip Hoisting at Illinois Coal Mines,** by Arthur J. Hoskin. Prepared under a co-operative agreement between the Engineering Experiment Station of the University of Illinois, the Illinois State Geological Survey and the U. S. Bureau of Mines. Price, 35c. Bulletin No. 151. Pp. 66; 6x9 in.; illustrated. Describes the results of an investigation into the advantage claimed for skip hoisting.

**Fifth Annual Report of the Federal Power Commission:** 1925, Washington, D. C. Pp. 209; 6x9 in.; parts I and II.

Report of the Mining Engineer and Agent of the Girard Estate in Schuylkill and Columbia Counties, Pennsylvania, for the Year 1924. Pp. 56; 6x9 in.; tables.

**Coal Statistics for Canada** for the Calendar Year 1924. Dominion Bureau of Statistics, Ottawa, Canada. Pp. 96; 6½x9½ in.; tables.

**The Support of Underground Workings in the Coal Fields of Scotland.** Safety in Mines Research Board Paper No. 12, H. M. Stationary Office, Adastral House, Kingsway, London, England. Pp. 24; 6x9½ in.

## Trade Literature

**Cleveland Worms and Gears.** The Cleveland Worm & Gear Co., Cleveland, Ohio. Bulletin No. 105. Pp. 15; 8x11 in.; illustrated. Dimension tables and drawings of standard gears and worm mountings are included, together with a list of gear ratios available on standard centers.

**Industrial Control Catalog.** General Electric Co., Schenectady, N. Y. Catalog 6001B, superseding all previous catalogs, with the exception of those dealing with railway, mine and industrial supplies and merchandise products. Pp. 1100; 8x10½ in.; illustrated. The catalog is thumb-indexed into 16 sections, some of which cover generation, wire and cable, distribution transformers, arresters, voltage regulators, switchboards and accessories, meters and instruments, motors, etc. The products are classified both by subjects and by catalog numbers in the indexes.

A convenient chart for the use of engineers who have occasion to calculate quantities connected with the expansion of steam is being distributed by the De Laval Steam Turbine Co., Trenton, N. J. The well-known Mollier diagram is printed upon a stiff sheet of bristol board, attached to which is a scale that can be broken off and used directly for measuring heat available, etc.

General Electric Co., Schenectady, N. Y., has issued a four-page folder describing and illustrating its single-stage centrifugal **air compressors.**

**Electrical Drives for Power Plant Auxiliaries** is the title of circular 7381, recently issued by the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. The circular is well illustrated.

**Sangamo Meters.** Sangamo Electric Co., Springfield, Ill. Bulletin No. 70. Pp. 23; 8x10½ in.; illustrated. Describes the Sangamo type H single and polyphase watt-hour meters.

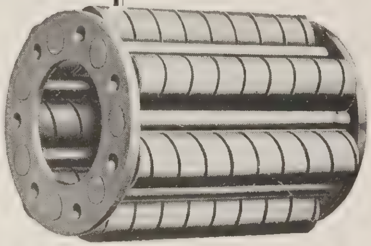
**Greater savings in labor, time, power, lubricant and upkeep come from the higher thrust, shock and radial capacity of Timken Tapered Roller Bearings. The difference in economy is so marked that Timkens are displacing every other means of mounting mine car wheels.**

TIMKEN *Tapered Roller* BEARINGS

# "I have succeeded"

said the purchasing official, with evident exultation, "in getting our next lot of mine cars cheaper than those we bought last spring. I got prices from several manufacturers. I will have to watch to see that all specifications are lived up to. They certainly figured low."



The General Manager of Mines picked up the order form and fingered it thoughtfully.

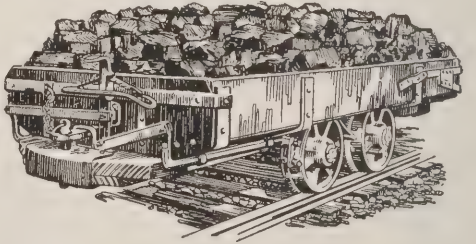
"As a purchasing Agent you have done exactly right," he said "But now look at this business a moment as I have to look at it—as a manager concerned with production and the cost per ton.

"Take this plant, for instance, the tipple equipped with labor-saving devices, the best mining machines we could find, modern locomotives and an expensive group of efficient mine executives who know how to produce coal 'backwards' at a good cost. We could have built and equipped a cheaper plant and I could get much lower priced men.

"Now our mine cars are but a part of the fabric of the whole plant—yet they are the bottle-neck of our production, for transportation from the face to the tipple and the cost of same frequently spells the difference between a poor return or a satisfactory return upon an investment."

"What do you suggest?"

"I suggest that you pick from the group of manufacturers you got in touch with first, three or four whom you know are capable of building good cars—they are the only ones we can afford to buy—and get proposals and interview their representatives, and we will get together with the operating heads and decide who will get the business. Your inquiries specify Hyatt bearings don't they? They are our standard."



"Yes sir, I am sure your superintendents wouldn't consider any other kind."

## Saving Anthracite

"ELECTRIFY!" IS THE INJUNCTION many an engineer has given anthracite producers who wonder how to cut down the tonnage of their own coal consumed at the mines. The Glen Alden Coal Co. is obeying the injunction. The story of how it reduced its power house consumption to a scant 7.8 per cent of its total production in 1924 is told in next week's issue of *Coal Age* by C. R. Seem, the company's electrical engineer.

The Glen Alden properties are highly electrified because the records prove that it pays to run mines on that basis. The quantity of steam used to generate electrical energy for motors is, in most instances, less than one-third that necessary to drive steam-operated equipment. On an average, 76 lb. of coal were required under the boilers for every horsepower-hour of work done at the shaft of a steam engine and but 29 lb. to generate electricity for the same unit of power. This sort of thing does its own convincing.

FAILURE OF CONCRETE SHAFT LININGS is another subject treated interestingly in the forthcoming issue. Newell G. Alford, of Pittsburgh, has concluded, after an exhaustive study of such linings in Pennsylvania, that most of the 30 failures out of 105 cases he covered were due to poor drainage behind the shaft walls. Even the best of concrete aided by design and workmanship above reproach cannot withstand the presence of much water behind the lining. Many a mining man will realize this after he reads Mr. Alford's article next week.

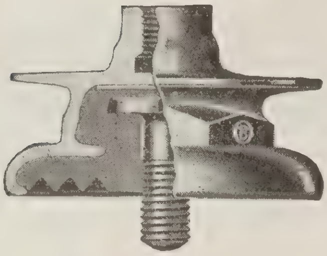
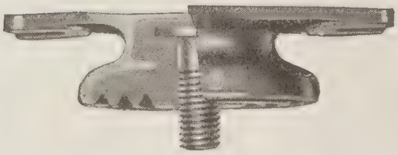
*ROOF — TIMBER — PIPE — I-BEAM*

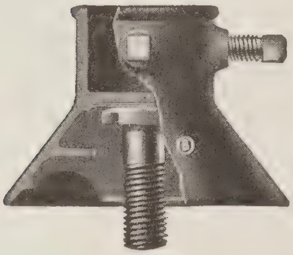
# Insulated Hangers



**Type K—for roof**



**Type H—for timber. With clamp, for I-beam**



**Type U—for pipe**

There is quite a variety in the different types of O-B insulated Hangers. But that is not evidence that O-B has tried to see how many different designs could be originated.

It is evidence of a wide experience in mine electric haulage. The many types have been developed from actual contact with a variety of mine trolley requirements.

And back of this is an active engineering organization willing and anxious to apply information gathered from work at many properties to those problems peculiar to your property.

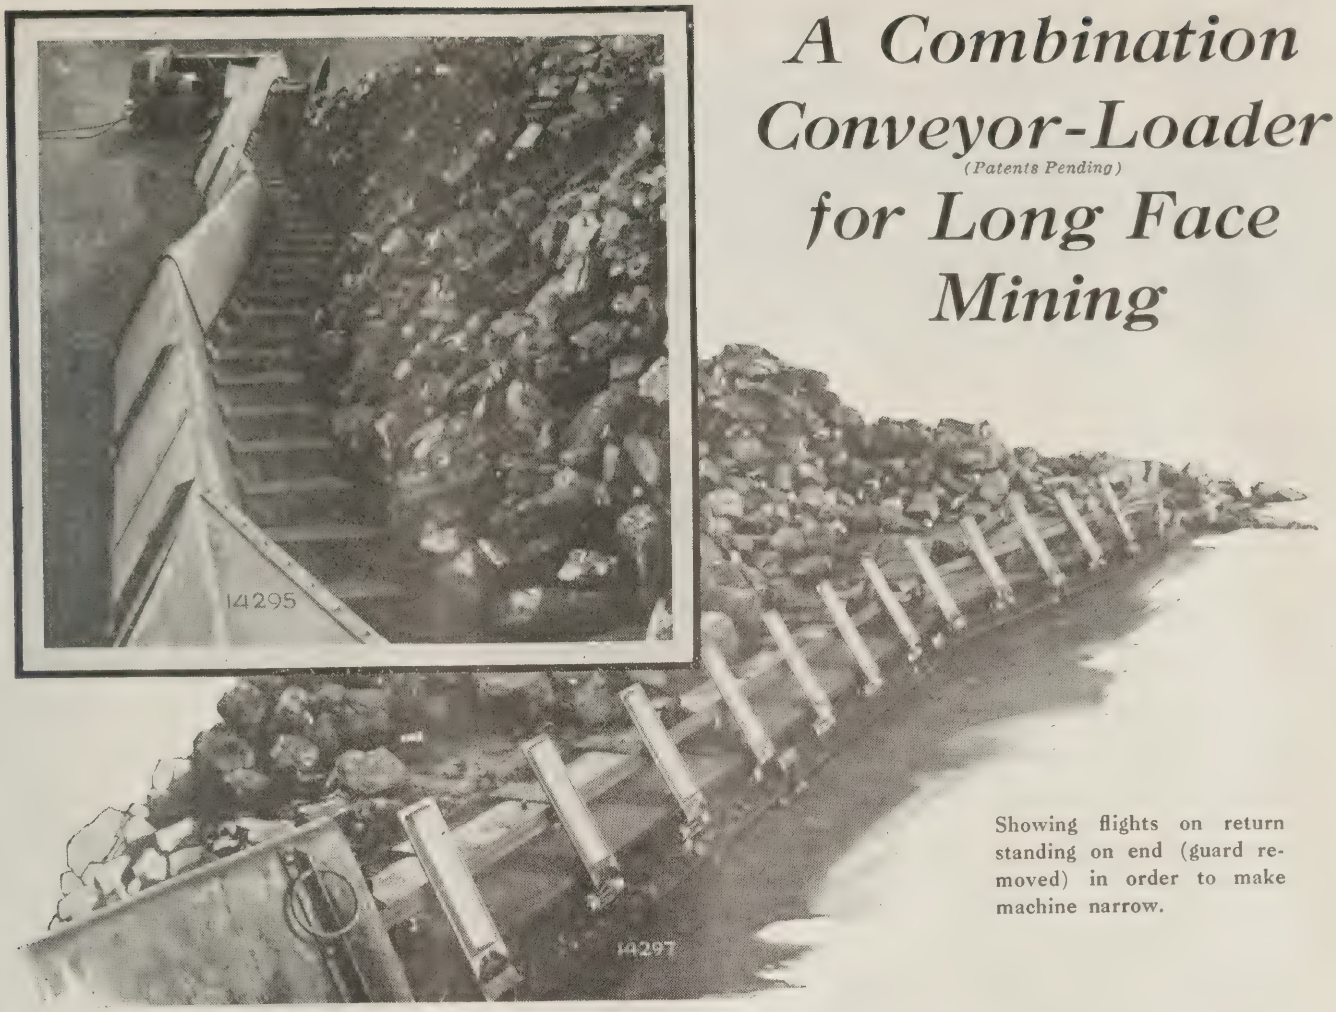
**TROLLEY MATERIAL**

# *A Combination Conveyor-Loader* *(Patents Pending)* *for Long Face Mining*



Showing flights on return standing on end (guard removed) in order to make machine narrow.

THE Jeffrey 44B Machine is a self-loading sectional conveyor and is used on faces preferably 100 ft. or more in length.

After coal has been undercut and shot, the conveyor is pushed into the loose material, the flights picking it up and carrying it away, along the face to a sectional conveyor which delivers it to either mine cars or to still another conveyor.

Built extremely low—the flights travel practically on the mine floor. Larger pieces can be readily rolled onto the conveyor than can be lifted into other types.

Made up in sections 10½ feet long—coupled together with a universal joint—can be quickly lengthened or shortened.

*Send for complete information on the Conveyor-Loader and other Jeffrey Equipment for Aiding Concentrated Mining.*

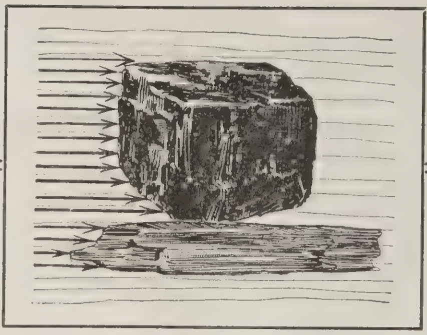
**COAL MINE EQUIPMENT**



# *What does* Rhéolaveur *mean?*

Rhéolaveur (French) translated means Current Washer.

The Rhéolaveur Process depends upon current washing for its primary classification. It utilizes the principle of specific gravities of the particles of coal, bone and slate, combined with the resistance their size and shape offers to a horizontal current of water.

By subjecting a mass of raw unwashed coal to a stream of water down an incline, the heavy slate quickly goes to the bottom of the chute and is slowed down by the friction against the bottom, while the lighter and more round coal tumbles over this lower strata and travels in a strata of its own making on top.

The Rhéolaveur Process utilizes this principle in a manner to get the greatest possible benefit from this phenomena.

This is the meaning of the name Rhéolaveur.

***Write for further details and be sure to read the Rhéolaveur advertisements in the coming issues of Coal Age***

# Sharp curves—
# *What if there are?*

No danger of derailments around sharp curves when a Vulcan Trolley Locomotive is doing your hauling. Due to the 3-point suspension of the chassis and other shock and strain absorbing features, this Vulcan Electric Locomotive adjusts itself to sudden turns as well as bumps and abrupt grades. The service life is prolonged just as the life of the Vulcan Steam Locomotive which has records of 30 and 40 years on a job.

Look over the features listed in the panel on this page and send for the story complete.

McCormick Bldg.

*Established* 1849

VULCAN *of* WILKES-BARRE
VIW LOCOMOTIVES

## How and why it's built like the Vulcan Steam Locomotive

Here is the answer to the demand of the industry for a Trolley Locomotive with the same shock-resistant, long-service features as the Vulcan Steam Locomotive.

### 3-Point Suspension

This 3-Point Suspension of the entire chassis is an exclusive feature of the Vulcan Trolley Locomotive. One pair of springs supports the frame through one set of hangers. One end of another pair of springs is held by other hangers. The opposite ends of the springs engage an equalizing bar extending across the machine and supported in the center. By means of this arrangement shocks are absorbed, the weight is evenly distributed and the locomotive runs smoothly over any ordinary inequalities of track.

### Other Features

Cast Steel Bar Frame

Each side frame is cast in one piece and of steel bar design, thus combining maximum rigidity as well as accessibility. The open spaces permit ample ventilation and simplify inspection.

Brake Rigging

The powerful, easily operated brakes, like the other two features, have been adopted in a large degree from Vulcan Steam Locomotive practice.

# "Should We Buy or Generate our Power?"

YOUR answer to this question should be based on facts! Either way your power bills are large enough to mount as power needs grow through increased mechanization and output.

Usually, if a proper water supply is available and load factors properly balanced, a coal mine of today's required capacity for economical production can burn its unmarketable coal in a well-designed power plant and generate its own power needs at less cost than central station service. Too often, however, antiquated equipment or needless operating expenses are responsible for abandoning mine power plants that might be regrouped or re-equipped with handsome returns on the investment. Too often the right choice is guessed at with either decision a mistake. And in too many instances inaccurate costs or *indifference* are wasting thousands of dollars yearly in excessive power bills.

Do you know your real power costs at present? Can they be reduced by a few simple changes in load cycles or distribution layout? Are you now scrapping mine waste that can be turned into kilowatts? Should you scrap or modernize your present plant? Can several wasteful plants be bunched to advantage in a high-efficiency "central" plant of your own? Or can you save real money by switching over to purchased power?

Allen & Garcia engineers are experienced in getting at the unprejudiced answers to these questions. Possibly the *correct* solution may have an unsuspected bearing on your costs-per-ton.

# Cheaper Air Power
## with an
# I-R Oil Engine Air Compressor

The Ingersoll-Rand Type "POC-2" Oil Engine Air Compressor illustrated will operate a 10-hour shift at full load on 60 gallons of fuel oil and ½ gallon of lubricating oil.

With fuel oil costing 6 cents per gallon and lubricating oil 60 cents per gallon, the operating cost for a 10-hour shift is less than $4.00.

At full load, the compressor will furnish sufficient air for operating continuously three R-72 "Leyner-Ingersoll" Drifters or eight BCR-430 "Jackhamer" Drills.

These oil engine air compressors are rugged, simple, and reliable. They are the cheapest source of air power. Skilled operators are not required.

# CHANCE COAL CLEANER

COAL cleaned by the Chance process always meets established standards —and more than this, it sets a standard of its own that is unequalled by the product of any other method of preparation.

The Chance Cleaner meets these requirements regularly, continually, dependably day by day, without regulation after it is once adjusted and without any retreating of the output. One cleaner has marketed very close to a million tons of all sizes, from egg to birdseye without a single car being condemned or rejected. For instance, one operator who has been using a Chance Cleaner for three years writes as follows:

> *"In spite of the fact that our coal shipments in all sizes run on an average of one per cent slate or less, we still find that our rock bank seldom exceeds one per cent of coal. We have tested under very rigid inspection at various times, both the coal going to market, and rock and slate going to spoil bank, and we claim that we are preparing the best coal in the anthracite region and our slate and rock bank is practically perfect."*

Other operators, who are using Chance Coal Cleaners, say:

> *"We obtain a much higher price for our coal." "The preparation of the coal is perfect from egg down to and including barley."*

The necessity for meeting higher standards in the production of Anthracite is daily becoming clearer and more urgent, and the operator who equips his operation to produce the cleanest and best coal is the one who will retain his markets under competitive conditions and realize maximum returns. This is one of many ways in which the Chance Cleaner increases profits. Others are dealt with at length in a series of advertisement reprints that will be sent you upon request.

**PORTER**
"better built"
locomotives

# PORTER LOCOMOTIVES

**The car that fits the needs of Northumberland Mining Co.**

# Of big capacity for both hard and soft coal mines!

You would expect such a big capacity car as this (113 cubic feet water level) when built for the anthracite field, to be 9 to 12 inches higher. But the Northumberland Mining Company wanted it to meet the requirements of the bituminous fields too. So "Car Foundry" Engineers designed it accordingly—only 4 ft. $\frac{5}{8}$ inches overall, from the top of the rail.

It is a composite steel and wood proposition. A $2\frac{1}{2}$-inch wood floor, covered with $\frac{1}{4}$-inch steel plate, acts as a cushion for buffing and provides, at the same time, a wearing surface to stand the gaff of mechanical loading and end gate dumping.

It has an adjustment for bearing outside the wheels, allowing the wheels to be replaced without difficulty—a low-maintenance-cost feature which bids fair to gain wide popularity in the mining industry.

"Whatever your car needs, you can depend upon Car Foundry" Engineers to design and build the type most suited.

*Get a "Car Foundry" quotation before you buy.*

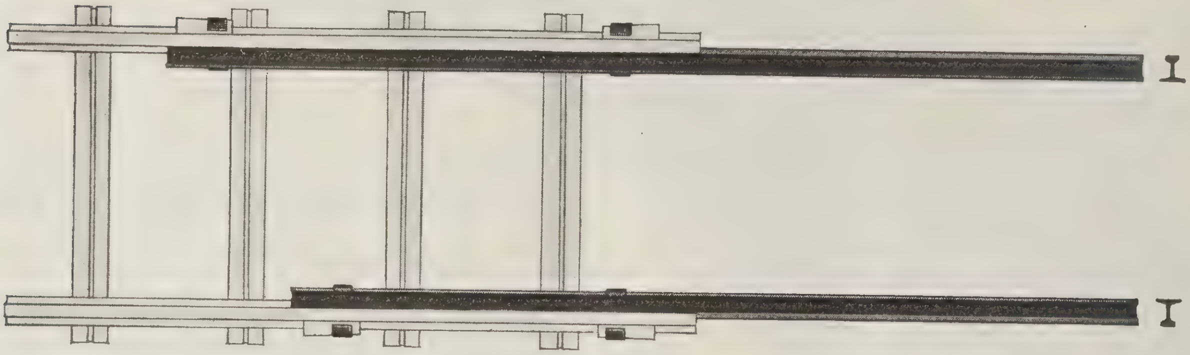
Grimm Rail Clamp

Grimm Rail Clamps provide a quick and handy means of extending track. The clamps firmly hold the rails together, and under load the flanges of the "Balled" rails become embedded in the mine floor, preventing spreading and offering great rigidity for Arc Wall Mining Machines.

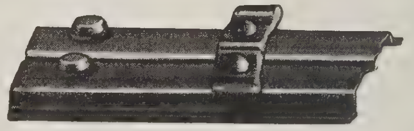


# How to save money!

THE problem of how to save money in extending or "balling" track at the mine face has been efficiently and economically solved for you in the Grimm Rail Clamp.

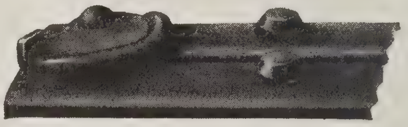
This is how it is done. The use of Grimm Rail Clamps lessens the amount of capital invested; eliminates the use of six ties at each mine face; gives more clearance for mine cars which allows bigger loads; and if wooden ties are used the saving in the cost of spikes, at each mine face, will almost buy a set of clamps. In addition to the foregoing, Grimm Rail Clamps save time and labor, thus increasing production.

There is nothing about the clamp to wear out—you can use it for years. Let us demonstrate the many advantages and money-saving features of the Grimm Rail Clamp.



**The Bethlehem "Standard" Tie**

For general use in Mining and Industrial track. Tie is made to fit any rail section from 16 lb. to 60 lb. per yard, and to any track gage.



The "Universal" Tie

This tie is made purposely to meet conditions where there are several different rail sections in use, and where severe corrosive conditions affect the rail base. The same tie will fit all rail sections from 16 lb. to 30 lb. per yard.

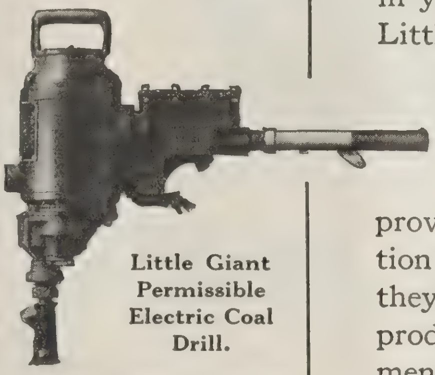
# Little Giant Electric Coal Drills

**For Use in Gaseous Mines**



**Little Giant Permissible Electric Coal Drill.**

All running parts of the motor are fully enclosed in a sealed motor housing. Furnished in Reversible and Non-reversible types for operation on direct current only, 115 and 250 volts.

WHATEVER may be the atmospheric conditions in your coal mine, there is a Little Giant Portable Electric Drill that will meet the need. Operators in every Coal Producing State have conclusively proven through the installation of these machines that they reduce costs, speed up production, crowd development and increase the percentage of lump coal.

The Little Giant Permissible Electric Drill shown at the left is approved by the U. S. Bureau of Mines for use in gaseous mines or dust laden atmosphere. Now every shot hole can be bored electrically, even though your mine is liable to outbursts of gas at the faces.

When Little Giant Drills are used, the whole mining operation is smoother, safer and speedier. Write for Bulletins containing full information.

# Lift yourself by your boot straps

THROUGHOUT the past year these advertisements have told you about Linde Process Service for Linde users. They have shown how it can help you, whether you have only a comparatively simple job, or whether you want to make the oxy-acetylene process part of your production work with all the managerial and engineering problems that this involves.

Linde Process Service goes even further. Under the title of Procedure Control, instructions are being assembled for every application of the oxy-acetylene process. So, when you ask for help, we shall be able to send you a set of instructions for your particular job. They will tell you how to select your materials, how to instruct your welders, how to set up and carry out the work, and how to test the finished job.

So you can, in reality, lift yourself by your boot straps. Linde Service men will always be available when needed, but, with the aid of Procedure Control alone, you will be able to apply the oxy-acetylene process to your manufacturing problems.

Next year our advertising will describe some of the outstanding achievements of the oxy-acetylene process in industry—achievements made possible by the use of Linde Process Service.

# Lubrication in a Nut Shell

Not long ago, a prominent industrial engineer asked, "Why don't the oil companies put out a lubrication chart for industrial machinery similar to the automobile charts now so popular all over the country?" Acting on his suggestion, and after a long, tedious research, we have produced the first of its kind for general distribution.

Here it is!

Every mine superintendent, every mine engineer, and everyone who has to do with mine lubrication should have one of these books. In addition to the lubrication charts, they contain a valuable treatise on Industrial Lubrication. This is not an advertisement; it is primarily an aid to industry as a whole, and everyone should avail himself of our offer to mail him a copy—gratis.

Use the coupon, if you like.

*Plant of the former Weir Frog Company, Cincinnati, Ohio*

*Plant of the former Kilby Frog & Switch Company, Birmingham, Ala.*

# A consolidation that doubles service facilities

This consolidation of the former Weir Frog Company and the Kilby Frog & Switch Co. of Birmingham, Ala., as the Weir Kilby Corporation, Cincinnati, Ohio, is in line with the Weir ideal of constant improvement in service to the coal mines of America.

Now, as never before, real efficiency is the prime necessity at all coal-mining property to meet the new-day conditions, and only those haulage tracks that are kept in good condition can handle the heavy trains at high speed that modern mining demands.

Well-built, rightly designed frogs, switches, switchstands, room turnouts, crossings, etc., for which the name WEIR and KILBY have both become recognized, must help mine operators maintain production schedules and keep production at rock-bottom costs.

"Wire Weir" now has a double significance. It means still better service! *Try it.*

WEIR KILBY CORPORATION
*Cincinnati, Ohio*

**WEIR**

**FROGS · SWITCHES · STANDS**

# Out'a track again!

*Always an unwelcome message*

When the loader's out of track—and the track crew's busy elsewhere you know what happens.

It means *that production costs are going up and tonnage is going down.*

If the loaders in ten rooms out of a hundred run out of track it means a ten per cent decrease in tonnage and a still bigger increase in costs.

Why run the risk? It is no longer necessary. Every loader equipped with a set of Tompkins' Extension Rails can put them in position himself in thirty seconds, and eliminate all temporary track laying costs. No ties, no spikes, plates, bolts, nuts, or tools.

Tompkins' Extension Rails come in 16 and 20 ft. lengths "Standard" and "Heavy Duty" weights. They slip right over the ends of permanent track. Strong, durable, and practically last forever.

Get a few sets and try them out. We know you'll like them. Your jobber will see that you are supplied promptly or write us.

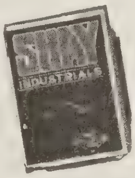
# How Shays Save Money In Strip Mine Hauling



*May we send you a copy of our catalog?*

SHAYS are saving their cost over and over again in many strip mines, by serving continuously and dependably over long periods of years, operating on inexpensive track, over steep grades and sharp curves.

"We are using six Shays," writes the Superintendent of one company. "They have been in service since 1908 and 1911 and are doing their work as well as new machines.

"They will operate on track that a rod engine could not move on."

This company is using various types of locomotives at their operations, but they say, "for traction and power, the Shay leads them all."

May we explain how powerful and dependable Shays can reduce your hauling expense?

Copyright 1924 by E. I. du Pont de Nemours and Company

It protects your mining property from three angles.

First—we *know* the *causes* of corrosion and decay of metal, wood and concrete in the coal industry and we will send experts to check up conditions in *your* particular property.

Second—we know the proper *composition* of paint to check rust, decay or corrosion under any given conditions.

Third—our experts will select the correct paint for any given protective problem—not merely paint, but the *right* paint for the circumstances and materials.

This Service covers all your mine or any part of it. Let a Du Pont expert call to make recommendations.

## Scottdale Coal Tipple Equipment

Screens, picking tables, shakers, loading booms, feeders and other Scottdale coal mining machinery, are all designed to handle coal efficiently and with minimum breakage.

25 years' experience in the design and manufacture of coal tipple equipment, with intimate contact with the development of mining practice, qualifies the Scottdale engineering staff.

Besides manufacturing coal tipple machinery we also design and erect complete coal-handling plants.

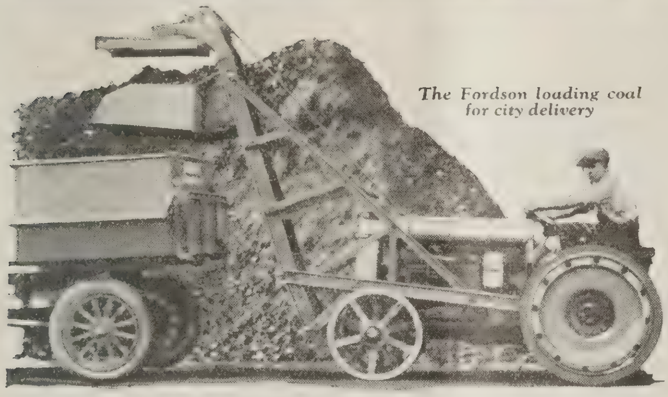
Fordson with 5-Ton Dump Body Trailer used for coal deliveries by Campbell Coal Co., Memphis

# Fordsons are Low-Cost, Full-Time Coal Haulers



The Fordson loading coal for city delivery

Fordson Tractors are taking the place of heavy, expensive hauling equipments in many of the leading coal yards of the country. The investment is only a fraction of the cost of heavy duty trucks.

The Fordson with shovel equipment or conveyer bucket loaders can also eliminate the costly expense of hand loading. This is another of the many jobs in which the Fordson proves extremely useful around coal yards.

Your nearest Authorized Ford Dealer will gladly show you facts concerning Fordson performance in the coal business. Let him substantiate these claims with a complete Fordson demonstration in your yards.

Ford Motor Company
DETROIT, MICH.

Dumping the load right where it is wanted.

# Sure Grip

MANY "improved" trolley clamps have been put on the market since the Sure Grip was first produced but after seventeen continuous years, the Sure Grip still remains the standard. Engineers of this company have found no possible way to improve upon the Sure Grip design and apparently no other manufacturer has been able to produce as good a clamp.

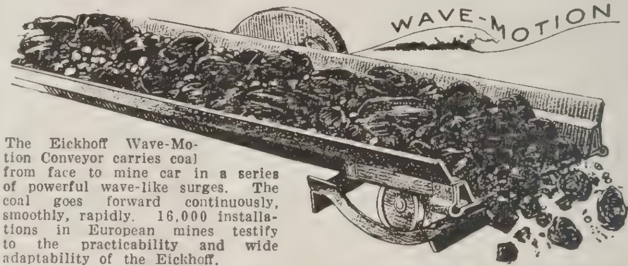
## IT CONVEYS COAL WITH A



The Eickhoff Wave-Motion Conveyor carries coal from face to mine car in a series of powerful wave-like surges. The coal goes forward continuously, smoothly, rapidly. 16,000 installations in European mines testify to the practicability and wide adaptability of the Eickhoff.

**Conveyor Sales Co., Inc.**

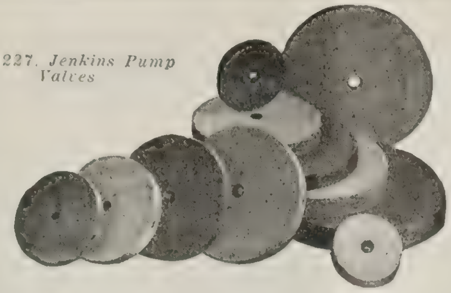

*Fig. 227. Jenkins Pump Valves*

## Get a pump valve to fit the service

In its composition a pump valve must fit the service in which it is to be used, the fluid handled and the pressure the pump is working against.

Jenkins Pump Valves afford the engineer a range of choice which assures him of the proper valve. A schedule of these pump valves and the service for which each is guaranteed is yours for the asking.

## MINING MACHINERY

3—SA-1090 Morgan-Gardner Shortwall machines.
1—4½-ton Jeffrey Gathering Locomotive.
1—150-Kw., 250 volt D.C. Generator. Belt Drive.
1—250 HP., 18x18 Skinner Automatic Engine.
1—Harrisburg Engine Direct Connected to General Electric 160 Kw., 275 volt, 160 r.p.m. Generator.

**The Hocking Valley Mine Supply Company**
Athens, Ohio

---

## BELTING FOR SALE

New, approximately 400 ft. 18-in. width, 5/16-in. thick, rubber faced rubber belting. Will be sacrificed for immediate disposal.

Communicate with

**M. L. TUCKER, LENA RUE COAL CO.**
Lenarue, Kentucky

---

FOR SALE

## POWER PLANT

All or part interest in a Hydro Electric and Power Plant, located on the Eagle River in Colorado.

**PERRY STEELE, Gypsum, Colorado**

---

## Opportunity to Secure a Synchronous Convertor At A Saving Of 40%

**200 kw. General Electric Mine Type HCC, 250 v., 800 amp. compound wound interpole D.C., 6 ph., 60 cy., 1200 r.p.m. unit, complete with brush lifting device, end play device, speed limit device and squirrel cage winding for self starting from A.C. end. This unit has been completely overhauled, is in condition equal to new and ready for immediate shipment.**

**The Fuerst-Friedman Co.**
**Cleveland, Ohio**

---

## SYNCHRONOUS MOTOR GENERATOR SETS

1—65 kw., 250-v. D.C., 2200-v., 3-ph., 60-cy. A.C. Milwaukee Westinghouse.
1—150 kw., 250-v. D.C., 2200-v., 6-ph., 60-cy. A.C. Westg. rotary.
2—200 kw., 275-v. D.C., 2200/6600-v., 3-ph., 60-cy. A.C. Westg. rotary.

## DIRECT CONNECTED STEAM ENGINE GENERATOR SETS

1—50 kw., 250-v. D.C. General Electric Skinner.
1—75 kw., 250-v. D.C. Crocker-Wheeler Steam Engine Co.
1—150 kw., 250-v. D.C. Burke Harrisburg.
1—250 kw., 250-v. D.C. General Electric Ball.

## MINING MACHINES

1—250-v. D.C., 27-A Jeffrey Breast Machine.
8—250-v. D.C. CE-7 Sullivan Shortwall Machines.
3—250-v. D.C. 35-B Jeffrey Shortwall Machines.
2—250-v. D.C., 28-A Jeffrey Shortwall Machines.
6—250-v. D.C. 12-DA Goodman Shortwall Mining Machines.
1—250-v. D.C. 112-AA Goodman Shortwall Mining Machine.
1—250-v. D.C. 12-AB Goodman Shortwall Mining Machine.
2—220-v., 3-ph., 60-cy. Sullivan or Goodman A.C. Machine.

**Track gauge can be changed to suit your requirements.**

## LOCOMOTIVES

2—3-ton, 42-in. gauge, 250-v. D.C. 1600-K Goodman Gathering Locomotives.
4—4-ton, 39-in. gauge, 250-v. D.C. Morgan Gardner Gathering Locomotives.
1—5-ton, 36-in. gauge, 250-v. D.C. General Electric Gathering Locomotive.
1—6-ton, 30-in. gauge, 250-v. D.C. Jeffrey haulage locomotive.
4—7-ton, 36-in. gauge, 250-v. D.C. Goodman haulage or gathering locomotives.
2—7-ton, 38 or 42-in. gauge, 250-v. D.C. Westinghouse Bar Steel Frame Locomotives.
2—8-ton, 38 or 42-in. gauge, 250-v. D.C. Westinghouse Bar Steel Frame Locomotives.
1—8-ton, 36-in. gauge, 250-v. D.C. General Electric Locomotive, with reel.
3—10-ton, 36-in. gauge, 250-v. D.C. Jeffrey Haulage Locomotives.

***The electrical resistance of UNA Rail Bonds is extremely low because the return current passes from rail to rail through copper and copper only.***

*The UNA Bond is made of copper.*

*It is welded to the rail with copper.*

*In the welding operation every strand of the bond becomes a part of the welded bond head.*

*The area of contact of the copper to steel weld is six times the area of the bond itself.*

***With a continuous, unbroken path of copper from rail to rail the unusually high electrical conductivity of UNA Rail Bonds is an easily understood fact.***

*Send for a sample of a UNA Copper to Steel weld.*

**UNA Welding and Bonding Co.**
Cleveland, Ohio

*UNA Rail Bonds, Processes, Molds and Mold Parts fully protected by U. S. Letters Patent.*

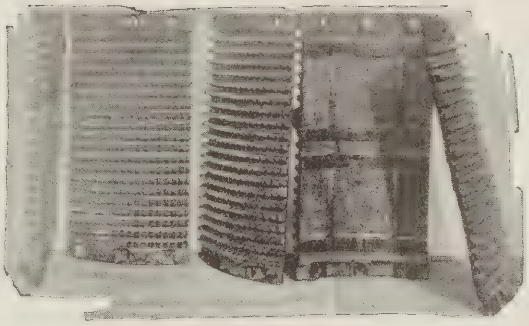
# "Tool Steel" Crusher Segments Outlast Manganese Steel



In Segments and in rolls for crushing coal, careful tests show that "Tool Steel" material will outlast manganese in the ratio of about 4 to 1.

Send us your inquiries and blueprints.

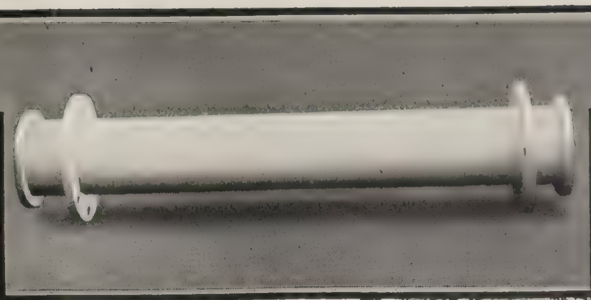
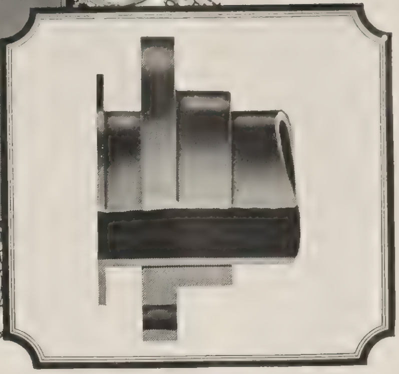
Reinforced Van Stone Joint Showing Square Corner



A length of Van Stoned Reading Pipe, ready for installation.



Reinforced Square Corner Van Stone Joint showing Loose Flange.

# *An Accomplishment of Interest to the Engineering Profession*

Ever since the Van Stone joint was perfected, it has been the desire of the engineering profession to successfully Van Stone genuine wrought iron pipe. Owing to the structure of this metal, however, the very quality (the siliceous slag content) which protects genuine wrought iron from corrosion was that which prevented the formation of the square-edged, strong flange required for a perfect Van Stone joint.

During the past two years, however, a new method of fabricating this joint has been perfected and a number of jobs with Van Stoned Reading Pipe have been installed with the greatest success.

It is no longer necessary to use less enduring pipe in power plants. Reading Genuine Wrought Iron Pipe can be used throughout, including all sizes that are to be Van Stoned.
